Authors of Volume 13

Dr S. van Balen

Honorary Researcher, Zoological Museum, University of Amsterdam, Amsterdam, The Netherlands.

Professor R. A. Cheke

Professor of Tropical Zoology, Natural Resources Institute, University of Greenwich at Medway, Kent, England.

Dr L. Christidis

Assistant Director and Head of Research and Collections, Australian Museum, Sydney, New South Wales, Australia.

B. J. Coates

Publisher and freelance ornithological consultant, Brisbane, Queensland, Australia.

Professor H. A. Ford

Division of Zoology, University of New England, Armidale, New South Wales, Australia.

P. A. Gregory

Professional bird guide and field ornithologist, Field Guides Inc. & Sicklebill Safaris, Kuranda, Queensland, Australia.

S. Harrap

Freelance ornithologist, naturalist and photographer, Norfolk, England.

P. J. Higgins

Consultant ornithologist and science editor, Sawtell, New South Wales, Australia; also, Senior Editor Handbook of Australian, New Zealand and Antarctic Birds (HANZAB).

Dr P. J. Jones

Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, Scotland.

Dr R. S. Kennedy

Director of Natural Sciences, Maria Mitchell Association, Nantucket; also, Associate, Ornithology Department, Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts, USA.

Dr H. Löhrl

Formerly Head of the Vogelwarte Radolfzell, Max Planck Institute for Behavioural Physiology, Radolfzell, Germany. Deceased.

S. C. Madge

Freelance wildlife consultant and writer; also, President, Cornwall Bird-watching & Preservation Society, Cornwall, England.

Dr C. F. Mann

Freelance ornithologist/biologist, London, England.

Dr H. C. Miranda

Assistant Professor, Department of Biology, Texas Southern University, Houston, Texas, USA.

Professor I. Newton

Emeritus Fellow, Centre for Ecology & Hydrology, Monks Wood Research Station, Huntingdon, England.

D. H. de Swardt

Head of Ornithology Department, National Museum, Bloemfontein, South Africa.

Dr B. A. Walther

Science Officer, DIVERSITAS, Muséum National d'Histoire Naturelle, Paris, France.

M. G. Wilson

*Honorary Research Associate, Edward Grey Institute, Department of Zoology, University of Oxford;
also, freelance translator and editor (ornithology), Oxford, England.*

Dr J. C. Z. Woinarski

*Principal Scientist, Biodiversity Conservation Division, Department of Natural Resources,
Environment and The Arts; also, Adjunct Professorial Fellow, School for Environmental Research,
Charles Darwin University, Northern Territory, Australia.*

Foreword

Bird Migration

The term migration, as used by ornithologists, is usually understood as a regular, large-scale return movement of individual birds twice each year between restricted breeding and wintering areas. Non-migratory birds are usually described as sedentary or resident because they occupy the same areas year round, and their populations show no obvious seasonal shifts in distribution. However, closer examination of bird behaviour reveals a more complex and variable array of movement patterns, which for convenience can be divided into six main types (after Newton 2008):

- **Routine movements** centred on the place of residence. As part of everyday life, such movements occur in all birds, whether classed as resident or migratory. They include the flights from nesting or roosting sites to feeding sites, or from one feeding site to another. In most birds these movements are short and localised, restricted to a circumscribed home range, and extending over distances of metres or kilometres. But in other species (notably pelagic birds) regular foraging movements can extend over hundreds of kilometres out from the nesting colony.
- **One-way dispersal movements** also occur in both sedentary and migratory bird species. After becoming independent of their parents, young birds typically disperse in various directions from their natal sites. Individual young seem to have no specific inherent directional preferences, so within a population, dispersal movements occur randomly in all directions, unless constrained by local topography. In most bird species, dispersal distances can be measured in metres, kilometres or tens of kilometres, but in a few species (notably pelagic birds) such distances can be much greater. Post-fledging dispersal of this type does not usually involve a return journey (see below), but in any case most surviving young subsequently settle to breed at some distance from their hatch-sites (called natal dispersal). In addition, some adults may change their nesting locations from year to year (breeding dispersal), or their non-breeding locations from year to year (non-breeding or wintering dispersal). In general, dispersal movements cause no seasonal change in the centre of gravity of a population or in its overall geographical distribution.
- **Migration** in which individuals make regular return movements, at about the same dates each year, often to specific destinations. Compared with the above movements, migration usually involves a longer journey over tens, hundreds or thousands of kilometres and in much more restricted and fixed directions. Most birds spend their annual non-breeding period at lower latitudes than their breeding period. Such migration occurs primarily in association with seasonal changes in food availability, resulting from the alternation of warm and cold seasons at high latitudes, or of wet and dry seasons in the tropics. Overall, directional migration causes a massive movement of birds twice each year between regular breeding and wintering ranges, and a general shift of populations from higher to lower latitudes for the non-breeding season.
- **Dispersive migration** in which post-breeding movements can occur in any direction from the breeding site (like dispersal), but still involve a return journey (like other migration). Although these movements occur seasonally between breeding and non-breeding areas, they do not necessarily involve any change in the latitudinal distribution of the population, or any change in its centre of gravity. They are evident in some landbird species usually regarded as ‘resident’, but also include altitudinal movements in which montane birds shift in various directions from higher to lower ground for the non-breeding season. In addition, many seabirds can dis-

perse long distances in various directions from their nesting colonies to over-winter in distant areas rich in food, but returning to their colonies the following spring.

- **Irruptions (or invasions)** are like other seasonal migrations, except that the proportions of birds that leave the breeding range, and the distances they travel, vary greatly from year to year (the directions are roughly the same but often more variable between individuals than in regular migration). Such movements are usually towards lower latitudes, and occur in association with annual, as well as with seasonal, fluctuations in food supplies. In consequence, populations may concentrate in different parts of their non-breeding ranges in different years. Examples include some boreal finches that depend on sporadic tree-seed crops, and some owls that depend on cyclic rodent populations.
- **Nomadism** in which birds move from one area to another, residing for a time wherever food is temporarily plentiful, and breeding if possible. The areas successively occupied may lie in various directions from one another. No one area is necessarily used every year, and some areas may be used only at intervals of several years, but for months or years at a time, whenever conditions permit. The population may thus be concentrated in largely different places in different years. This kind of movement occurs among some rodent-eating owls and raptors of tundra and boreal regions, and among many birds that live in desert regions, where infrequent and sporadic rainfall leads to local changes in habitats and food supplies. Because these changes are unpredictable from year to year, individual birds do not necessarily return to areas they have used previously, and may breed in widely separated areas in different years.

These different kinds of bird movements intergrade, and all have variants, but in any bird population, one or two kinds usually prevail. Almost all bird species show post-fledging dispersal movements, in addition to any other types of movement shown at other times of year, and some species show both nomadic and irruptive movements. Through migration, irruption and nomadism, birds exploit the resources of mainly different regions at different times. The birds thereby maintain greater survival or reproductive success (and hence greater numbers) than if they remained permanently in the same place, and adopted a more sedentary lifestyle. In other words, because of their movements, populations probably persist at considerably larger size than they otherwise would.

The main variables in these different types of bird movements include: (1) the directions or spread of directions; (2) the distances or spread of distances; (3) the calendar dates or spread of dates; and (4) whether or not they involve a return journey. They also differ in whether they occur in direct response to prevailing conditions, or in an 'anticipatory' manner, in adaptation to conditions that can be expected to occur in the coming weeks, and leading birds to leave areas before their local survival would be compromised or arrive in other areas in time to breed when conditions there are suitable. Each of these aspects of bird movement behaviour can be independently influenced by natural selection, giving overall the great diversity of movement patterns found among birds, related to the different circumstances in which birds live. In the rest of this chapter, however, I shall be concerned primarily with regular seasonal migration—that large-scale seasonal shift in bird populations which has fascinated people throughout history, raising obvious questions such as why birds do it, where they come from or go, and how they find their way.

Migration as a product of natural selection

Migration might be expected to occur wherever individuals benefit more, in terms of survival or reproduction, if they move seasonally between different areas than if they remain in the same area year-round (Lack 1954). The usual reason why breeding areas become unsuitable during part of the year is lack of food. Such food shortages occur for many birds because plant growth stops for part of the year, and many kinds of invertebrates die or hibernate or become inaccessible under snow and ice. At high latitudes, daylengths also shorten in winter to such an extent that many diurnal birds would have too little time to get enough food, even if it were available. Hence, the purpose of the autumn exodus from high latitudes is fairly obvious.

The reason why birds leave their wintering areas to return in spring is sometimes less obvious, because many wintering areas seem able to support the birds during the rest of the year. But if no birds migrated to higher latitudes in spring, these latitudes would remain almost empty of many species, and a large seasonal surplus of food

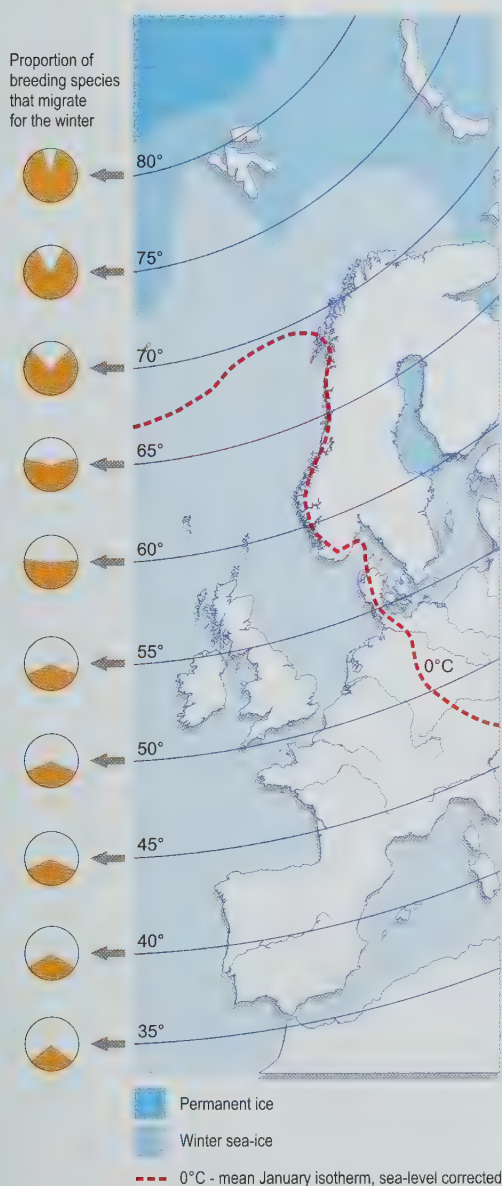

Snow Buntings (Plectrophenax nivalis).
Helsinki, Finland.
Markus Varesvuo.

would go largely unexploited. Under these circumstances, any individuals that moved to higher latitudes, with increasing food and long days, might raise more offspring than if they stayed at lower latitudes and competed with the birds resident there. So whereas the advantage of autumn migration can be seen as improved winter survival, dependent on better food supplies in winter quarters, the main advantage of spring migration can be seen as improved breeding success, dependent on better food supplies in summer quarters. Compared to survival, reproduction often has more stringent requirements in terms of specific food needs and predation avoidance.

In effect, migration reduces the seasonal fluctuations in food supplies to which a breeding population could otherwise be exposed. This does not rule out an influence of other factors, such as reduced predation, parasitism or competition, all of which have at one time or another been proposed as contributing to the evolution of migration, but on scant evidence. Whatever the main selective forces, however, the migratory habit ensures in the long term that species in seasonal environments adopt and maintain movement patterns that allow individuals to survive and breed better than if they remained in the same area year-round.

Global patterns

Figure 1
Map of western Europe showing the proportions of breeding bird species at different latitudes that migrate south for the winter.
From Newton & Dale (1996a).

Throughout the world, migration is most apparent wherever the contrast between summer and winter (or wet season and dry season) conditions is great. Migration thus allows individual birds to exploit different areas at different times of year, whether to benefit from seasonal flushes of food or to avoid seasonal shortages. In fact, some migratory birds occupy habitats over winter that they could not use for breeding, and then occupy breeding areas that would not support them in winter. This applies to all arctic nesting shorebirds which spend the winter on sea coasts where, due to tidal flooding, nesting would be impossible, and then migrate north to breed on the arctic tundra which is frozen and snow-covered for the rest of the year. Thus some bird species exist over much or all of their range only by exploiting widely separated habitats at different seasons.

Although most marked at high latitudes, migration also occurs in the tropics, especially in the savannahs and grasslands exposed to regular wet and dry seasons. In the northern tropics, for example, many species move south for the dry (non-breeding) season, some crossing the equator, while in the other half of the year many species of the southern hemisphere move north. In contrast, birds confined to lowland equatorial rainforest are probably the least migratory, especially the small insectivores of the understorey where conditions remain relatively stable and suitable year-round. This year-round consistency in the rainforest environment removes any advantage in moving, and many individuals may remain within the same few hectares throughout their adult lives. In the same forests, however, some nectar-eaters and fruit-eaters move within small latitudinal or altitudinal bands in response to flowering and fruiting patterns, while other birds from higher latitudes move in for their 'winter'.

In general, the proportions of species which are migratory increase from equatorial to polar regions, as the contrast between summer and winter conditions widens (Newton & Dale 1996a, 1996b). Progressing northward up the western seaboard of North Africa and Europe, for example, the proportion of breeding bird species which move out totally to winter further south increases from 29% of species at 30°N (North Africa) to 83% of species at 80°N (Svalbard), a mean increase of 1.3% of breeding species for every degree of latitude (Figure 1).

This relationship holds, it has been suggested, because at high latitudes the numbers of resident birds (species and individuals) are held at low level by winter severity. The flush of food in summer is greater than the small number of resident species can exploit, leaving a surplus available for summer migrants. The latter therefore increase in proportion with latitude, as the severity of the winters increase, and the numbers of year-round resident species decline. At lower latitudes, a large proportion of breeding species can remain year-round, leaving fewer openings for summer visitors (Herrera 1978, O'Connor 1985).

In the largely different avifauna of eastern North America, the proportion of migrants among breeding species also increases with distance northwards from 12% at 25°N to 87% at 80°N, a mean increase of 1.4% per degree of latitude (Figure 2; Newton & Dale 1996b). The difference between eastern North America and western Europe (Figure 2) reflects the climatic shift between east and west sides of the Atlantic: over most of the latitudinal range, at any given latitude winters are colder in eastern North America than in western Europe. Correspondingly, at any given latitude, a greater proportion (on average about 17% more) of breeding species leaves eastern North America for the winter than leaves western Europe. The slopes of the two linear

regression lines calculated from the data in Figure 2 do not differ significantly, but their positions do, reflecting this climatic difference.

On both continents, this northward trend in the prevalence of migration is easily understood in terms of winter conditions. In Europe, during much of the 20th century, mean January temperatures exceeded 10°C only in southern Spain and North Africa; they lay within the range 0–5°C in much of western Europe, but fell below freezing and as low as –15°C in most of Fennoscandia, plunging to –20°C in Novaya Zemlya in the far north. Minimum winter daylengths were around 11 hours at 35°N in southern Europe but decreased to zero at the Arctic Circle. The season of plant growth lasted 6–9 months at 35–50°N, but shrank to less than three months in Svalbard, a mean decline in growing season of about one month for every 11° of latitude. In continental western Europe, most fresh waters north of 55°N froze in winter, although they mostly remained open in Britain and Ireland. Much of the Baltic and Barents Seas also iced over during the course of the winter, closing these areas for seabirds. In North America, similar latitudinal trends occurred, but were more marked because the continent spans a wider range of latitude than Europe. Throughout much of these areas, winter temperatures are now rising, as part of ‘global warming’, and bird migration patterns are changing accordingly, but they still relate to gradients in prevailing conditions.

The few species that remain to winter in the far north include the Common Raven (*Corvus corax*), Rock Ptarmigan (*Lagopus mutus*), Gyrfalcon (*Falco rusticolus*) and Snowy Owl (*Nyctea scandiaca*) among landbirds, and the Northern Fulmar (*Fulmarus glacialis*), Ivory Gull (*Pagophila eburnea*) and Glaucous Gull (*Larus hyperboreus*) among seabirds. The most northerly seabirds depend in winter on the open water provided by polynyas, and some of the gulls also scavenge the remains of seals killed by Polar Bears (*Ursus maritimus*). However, some individuals of these species may move south to some extent in the darkest weeks of winter.

The relationship between the proportion of migrants and latitude, established above for Europe and North America, continues southwards towards the equator. There are insufficient data to examine the trend in detail, but by 8° latitude in Panama, only five (0.6%) out of 807 breeding species are wholly summer migrants (Ridgely & Gwynne 1989). This is consistent with the regression line between proportion of migrants and latitude derived from the data for North America in Figure 2. The five migratory species found at Panama are all insectivores which leave for the winter dry season and head further south, namely American Swallow-tailed Kite (*Elanoides forficatus*), Plumbeous Kite (*Ictinia plumbea*), Common Nighthawk (*Chordeiles minor*), Piratic Flycatcher (*Legatus leucophaius*), and Yellow-green Vireo (*Vireo flavoviridis*).

The proportions of all bird species that are migratory are correlated not only with latitude, but also with various climatic factors that vary with latitude, such as the temperatures of the hottest or coldest months or the temperature difference between the hottest and coldest months (Newton & Dale 1996a, 1996b). These various measures are of course interrelated, but what really matters is the degree of climatic difference between summer and winter. It is this difference that, for many birds, governs the difference in food supply between summer and winter at particular latitudes, and hence the difference in environmental carrying capacity between the two seasons.

The seasonal difference in carrying capacity may also vary from west to east, according to changes in climate (as between west and east sides of the Atlantic). From west to east across Europe, summer climates become warmer and drier, and winter climates become colder. In consequence, progressing eastward through Europe into Asia, increasing proportions of the local bird breeding species become migratory. This is especially obvious in comparing populations of coastal areas that live under mild oceanic climates with those further inland that live under more extreme continental climates. For example, Common Starlings (*Sturnus vulgaris*) live year-round on the Shetland Islands at 60°N, while at the same latitude in Russia (and for 10–15° south of it) Common Starlings are wholly migratory.

Superimposed on the overall latitudinal trend is another related to diet. Broadly speaking, those species that are resident year-round in a particular region exploit food sources that remain available there all year, whereas those that leave after breeding exploit foods that disappear about that time. In the northern coniferous forests, for example, residents include mainly species that feed directly from trees, on bark-dwelling arthropods (tits, treecreepers), fruits and seeds (some corvids, finches, tits), buds or other dormant vegetation (grouse), or that eat mammals and other birds (some corvids, raptors and owls). Almost the entire resident landbird fauna at high northern latitudes falls into one or other of these dietary categories. In contrast, species that depart for the winter include those which eat active leaf-dwelling or aerial insects (warblers, hirundines) or which eat foods that become inaccessible under snow or ice (ground feeding finches and thrushes, some raptors, waterfowl and waders). Towards the equa-

Figure 2

Proportions of breeding bird species (y-axis) at different latitudes (x-axis) in western Europe and eastern North America that migrate south for the winter. On regression analysis for western Europe: $y = 41.49 - 1.03x + 0.02x^2$, $r^2 = 0.97$, for eastern North America: $y = -75.05 + 4.33x - 0.3x^2$, $r^2 = 0.98$. The slopes of the regression lines from Europe and North America showed no significant difference, but the intercepts did differ ($F_{1,19} = 27.5$, $P < 0.001$), reflecting the climatic differences between west and east sides of the Atlantic. From Newton & Dale (1996b).

Figure 3
Latitudinal shift between summer and winter distributions of bird species that breed in western Europe. Includes wintering areas in Europe, Asia and Africa.
From Newton (1995).

tor, as winters become less severe, the range of bird dietary types that remain for the winter increases, as a wider range of food-types remains available year-round.

This relationship between migration and diet means that, in some mid-latitude areas, similar numbers of species may be present in summer and winter, but species composition changes somewhat between seasons, as some species from lower latitudes are present only in summer and other species from higher latitudes only in winter (Newton & Dale 1996a, 1996b). In southern England, for example, insectivorous swallows and warblers arrive from the tropics for the summer, whereas fruit-eating thrushes from further north arrive for the winter. Seasonal changes in bird communities in particular regions are thus tied to seasonal changes in the types of food available. This emphasises the point that migrants often exploit seasonal abundances in both their breeding and non-breeding areas. It is a strategy that, for obvious reasons, is much more developed in birds than in most other animals.

The overall effect of bird migration is to alter the latitudinal distribution of birds between summer and winter, so that species numbers in the northern hemisphere are at their greatest in the northern summer and in the southern hemisphere in the austral summer (northern winter). Take the west European migrants as an example. Some species move relatively short distances within Europe, but others move longer distances to Africa or southern Asia (Newton 1995). But the net result, each autumn and spring, is a huge latitudinal shift in avifaunal distribution (Figure 3). In summer, the whole European assemblage of breeding birds is (by definition) concentrated north of 25°N, but in winter the same assemblage extends southwards as far as the southern tip of Africa (35°S) and beyond. Forty-eight species of Palearctic birds reach the southern Cape of South Africa (Harrison *et al.* 1997), and some seabirds extend into the seas further south. When they are in their wintering areas, the migrants add to the local species, increasing the overall species numbers, especially in the tropics.

The above analyses (Figures 1-3) were based on the presence or absence of species at particular latitudes in winter. They were therefore based only on complete migrants, in which all individuals move out for the winter, while for purposes of analysis partial migrants (in which only a proportion of individuals leave for the winter) were counted as year-round residents. However, in many species that breed over wide areas, a greater proportion of individuals migrate from higher than from lower latitudes. Thus, some such species in the northern hemisphere are completely migratory in the north of their breeding range and completely sedentary in the south, while in intervening areas some individuals leave and others stay (partial migration). European examples include Common Blackbird (*Turdus merula*) and Peregrine Falcon (*Falco peregrinus*), and North American examples include American Robin (*Turdus migratorius*) and Red-tailed Hawk (*Buteo jamaicensis*). In general, therefore, the extent to which any population migrates for the winter broadly corresponds to the degree of seasonal reduction in food supplies. Taking account of partial as well as complete migrants, the latitudinal trends discussed above would be even more marked.

Altitudinal migration

By moving a few hundred metres down the sides of a mountain, birds can achieve as much climatic benefit as by moving several hundred kilometres to lower latitudes, but without the extra winter daylength. Mirroring the latitudinal trend, with rising altitude, increasing proportions of breeding species move out for the winter, but in contrast to latitudinal migration, altitudinal movements can be in any directions that reach lower ground. They occur on mountain ranges worldwide, from the Himalayas to the Andes, and can involve a large proportion of local montane species. Examples include the Citril Finch (*Serinus citrinella*) and Water Pipit (*Anthus spinoletta*) in Europe, and the Rosy Finch (*Leucosticte arctoa*) and White-tailed Ptarmigan (*Lagopus leucurus*) in western North America. Seasonal altitudinal movements occur even on relatively low mountains, such as the Great Dividing Range in southeast Australia, where several montane species appear in lowland towns and farms in winter.

Comparisons between hemispheres

Migration of landbirds from their breeding areas is a much more obvious phenomenon in the northern hemisphere than in the southern. This is partly because land covers three times the area in the northern hemisphere as in the southern hemisphere, and the difference is most marked at high latitudes (we can ignore Antarctica because it holds no landbirds). In North America, Greenland and Eurasia, some landbird habitat extends north of 80°N, but in the southern hemisphere, South America reaches

only to 55°S, Africa to 35°S, Australia to 43°S, and New Zealand to 47°S. The net result is that latitudes 30–80°N hold 15 times more land than do latitudes 30–80°S, and it is at these latitudes that winters are coldest, and migration is most developed (for discussion of area effects in South America see Chesser 1994, and in Australia see Chan 2001). The greater latitudinal spread of land in the northern hemisphere results not only in more marked migration, but also in generally longer journeys than are undertaken by southern hemisphere breeders, which are closer to the equator.

Another factor is temperature, which has a steeper downward gradient north of the equator than south of it. For example, in the New World the mean midwinter (January) temperature at the Tropic of Cancer is about 13°C, while at 50°N it is –15°C, a 28°C difference. In contrast, the mean midwinter (July) at the Tropic of Capricorn is 16°C, while at 50°S it is 0°C, a 16°C difference. Similar hemisphere differences are apparent in much of the Old World too. This difference in steepness of temperature gradient between hemispheres may explain why greater proportions of species leave from temperate latitudes in the northern hemisphere than in the southern. For example, about 29% of species leave completely for the winter from Morocco, but only 6% of species leave from equivalent latitudes around the Cape in South Africa (Harrison *et al.* 1997, Newton & Dale 1996a). It is presumably largely for both these land-related and temperature-related reasons that landbird migration is much more marked in the northern than in the southern hemisphere.

Regarding length of journeys, many landbird species that breed in the northern hemisphere migrate south of the tropics, yet no landbird species that breed in the southern hemisphere move north of the tropics. This may be because the much larger landbird populations of the northern hemisphere have to travel far to the south to find sufficient accommodation, while the smaller landbird populations of the southern hemisphere find sufficient accommodation by travelling relatively shorter distances to the north. This difference is another likely consequence of the imbalance in available land areas between the two hemispheres.

In extent of seasonal migration, pelagic seabirds provide a revealing contrast with landbirds. Associated with the reduced land areas in the southern hemisphere, the sea areas are correspondingly larger than in the northern hemisphere. Linked with these greater sea areas and larger numbers of scattered island breeding sites, pelagic seabirds breed much more numerous in the southern hemisphere than in the northern, both in terms of species and of individuals. Correspondingly, a greater proportion of southern than of northern hemisphere breeding seabird species make long migrations. Five (11%) of 47 species that breed north of the tropics extend to south of the tropics in the northern winter, whereas 14 (23%) of 61 species that breed south of the tropics extend to north of the tropics in the austral winter (calculated from maps in Harrison 1983). Some seabird species that breed in the southern hemisphere, such as Wilson's Storm-petrel (*Oceanites oceanicus*) and Sooty Shearwater (*Puffinus griseus*), are amongst the commonest seabirds in the North Atlantic and North Pacific in the northern summer (austral winter). The implication is again that the sheer numbers of individual birds, in relation to the habitat available, influence the distances moved and areas occupied outside the breeding season.

Species that migrate between the northern and the southern hemispheres gain the advantage of 'summer' conditions in both their breeding and non-breeding homes. The question then arises why the same individuals do not breed twice in one year, in both northern and southern quarters. One reason in many species is that individuals moult while in their non-breeding areas, a process that takes several weeks or months and could not be undertaken at the same time as breeding (the two processes being mutually exclusive in most birds). Another reason is that many migratory species do not remain for long in the same area in winter, but periodically move to other areas in response to changes in food supplies. This exploitation of temporary abundances is one way in which migrants in the southern hemisphere could avoid competing with the local birds which, breeding at that time, are tied to fixed nesting areas. Neither explanation applies to all trans-equatorial migratory species, however, and there are still some that are sedentary while they are in both breeding and non-breeding areas, and would seem able to breed in both, six months apart, but do not.

Sex and age differences

In many bird populations, sex and age differences occur in the proportions of individuals that migrate, in the timing of outward and return movements, and in the distances travelled. The latter give rise to geographical gradients in sex and age ratios from high to low latitudes across the wintering range. In many species, adult birds winter, on average, nearer to the breeding areas than first-year birds, and males,

Gulls and terns.
Khaluf, Oman.
Hanne & Jens Eriksen.

on average, nearer than females. Winter sex ratios have been studied in detail in the Common Pochard (*Aythya ferina*) in which the proportion of females in local flocks increases from north to south across the European wintering range (Carbone & Owen 1995).

Sex differences in migration within species can often be linked to the different roles of the sexes in breeding, and both sex and age differences partly to dominance and competition within populations, duration and timing of moult, and perhaps also to other (as yet unknown) factors. Thus, in many bird species, males are responsible for establishing nesting territories, and arrive in breeding areas before females. In addition, in species in which only one partner looks after the young, the other leaves breeding areas earlier (males in ducks, males in some shorebirds, females in other shorebirds). In Curlew Sandpipers (*Calidris ferruginea*), the males play no part in parental care, so depart early, leaving the females to raise the young. In Spotted Redshanks (*Tringa erythropus*), the opposite occurs, in that the females depart earlier, leaving the males to rear the young. In yet other waders, both partners help to the same stage with parental care, and the two sexes migrate at about the same time, as in the Northern Lapwing (*Vanellus vanellus*) and Black-tailed Godwit (*Limosa limosa*). Typically, in all these species, adults leave breeding areas earlier than young of the year.

Variants on a migratory theme

Several variants occur on the return two-way movement between regular breeding and wintering areas, associated with the ecology of the species concerned.

Moult migration

Moult migration is a regular movement which many waterbirds and others perform each summer, travelling long distances from their nesting areas to assemble at traditional sites that offer food and safety (Jehl 1990). Here they pass the flightless period, replacing all their large wing feathers simultaneously within the space of a few weeks. Geese migrate to moult mainly in latitudes higher than their nesting areas, but ducks migrate in any directions from their nesting areas. After moulting, depending largely on location, the birds may return to their nesting areas, move on to their wintering areas, or stay in their moulting areas all winter, returning to nesting areas in spring.

One of the best known moult migrations concerns Common Shelducks (*Tadorna tadorna*), in which individuals from large parts of Europe gather each summer on the vast tidal mudflats of the Grosser Knechtsand in the German Wadden Sea, where they feed on the abundant mud snail (*Hydrobia ulvae*). The birds converge on this site from all directions, travelling up to several hundred kilometres from their nesting areas. Their numbers peak at more than 200,000 individuals. Yearlings and young adults arrive first, followed by failed breeders, then successful adults which leave their well-grown young behind (Patterson 1982). After moult, the birds drift back to their breeding sites over a period of weeks or months or move on to wintering areas, depending on whether their particular breeding areas are habitable in winter. In some other duck species, individuals have been found by ringing to travel distances of more than 2000 km from breeding to moulting sites, and some of the biggest concentrations hold tens of thousands or hundreds of thousands of birds. In general, sea-ducks perform longer journeys than freshwater ducks. For example, King Eiders (*Somateria spectabilis*) from most of eastern Canada travel to coastal areas off mid-western Greenland to moult, travelling up to 2500 km, and forming a concentration of more than 100,000 birds (Salomonsen 1968). Moult migrations are also known among grebes, auks and other waterbirds.

Movements in the breeding season

Some multi-brooded bird species nest in more than one locality each year, migrating from one site to another during the course of the breeding season. Typically, individuals raise a brood in one locality, then migrate several hundred kilometres to another locality, and raise another brood. Such 'itinerant breeding' has been recorded in various seed-eaters, including the Red-billed Quelea (*Quelea quelea*) of the African savannas. Throughout the dry season, Red-billed Queleas subsist on dry grass seeds picked off the ground, but when the rains break, this seed suddenly germinates, thus removing the food supply. The birds then fly over the approaching rain front to areas

where rain fell about two months earlier and new grass seed has already formed. This new seed, together with insects associated with growing vegetation, enable the birds to breed. After raising their young, the birds move en masse, stopping again in an area where rain has recently fallen, and raise another brood (Jaeger *et al.* 1986, Ward 1971). Conditions suitable for rearing young do not last long in any one place, and despite a short breeding season of only five weeks, Red-billed Queleas cannot raise successive broods at the same place. Only by remaining within the slowly shifting zone of seedling grasses are individual Red-billed Queleas able to raise more than one brood per year, each time moving some hundreds of kilometres.

Itinerant breeding has also been suspected among Common Quails (*Coturnix coturnix*), as they breed first in North Africa and then in the northern Mediterranean region, and possibly a third time in temperate Europe, as spring begins progressively later with distance northward (Cramp 1980). It has also been suspected among Common Redpolls (*Carduelis flammea*) in northern Europe, as they breed first in the boreal forests as conifer seeds are shed from the opening cones, and then further north on the strength of birch and grass seeds (Peiponen 1967).

Movements in the non-breeding season

Many birds make long movements within the non-breeding season, usually to escape food shortages. Some such movements occur in response to depletion of fruit and seed crops, while others occur in response to cold and snow. For example, following the first heavy snow-fall in temperate latitudes, thousands of birds can be seen moving southwards, particularly ground-feeding species, such as plovers, larks, pipits and finches. Such escape movements vary from year to year, depending on the severity of the winter, and in years without serious snow, no such movements occur.

Nomadism

Apparent nomadic movements occur in species which exploit sporadic habitats and food supplies, concentrating temporarily wherever conditions permit. They are shown by some boreal finches which move around to exploit sporadic tree-seed crops, by certain owls which exploit the cyclic peaks of rodent populations, and by many desert bird species which move around in relation to irregular rainfall which generates their food supplies (Dean 2005, Newton 2008). Such species seem to show little year-to-year consistency in their movement patterns, but shift from one area to another, residing for a time in whichever parts of their range food is plentiful at the time.

Every few years, however, at times of widespread food-shortage, such species may move longer distances, and appear well outside their usual range. In the central Australian desert, the populations of many species increase greatly as a result of good breeding in occasional wet years, and then many individuals move outwards to the more humid peripheral districts in the following dry years (Nix 1976). Many birds probably die before they can return, but individuals of some species spend long periods in coastal localities and occasionally move inland to breed in vast numbers when rain creates suitable conditions. For example, Banded Stilts (*Cladorhynchus leucocephalus*) can live for years as non-breeders on scattered briny coastal lagoons. But within days of rain falling inland, they concentrate in tens of thousands on newly formed shallow lakes, feeding on the freshly-hatched swarms of brine shrimps (Burbidge & Fuller 1982, Robinson & Minton 1989). They breed while conditions last, making repeated nesting attempts, while the young form huge crèches. Water evaporates rapidly, however, and the land soon resorts to its usual parched state. The birds return to the coast, if necessary leaving the last eggs and young to die. Years may pass before they can breed again, but not necessarily in the same sites. A similar outward movement of desert species at times of widespread drought is illustrated in Eurasia by the westward movements of Rose-coloured Starlings (*Sturnus roseus*), Pallas's Sandgrouse (*Syrhaptes paradoxus*) and others from the steppes into western Europe.

One of the puzzles of nomadic birds, which seem to move in any direction from one breeding area to another, is how they find their way to suitable areas. One possibility is that they search at random, gradually settling wherever conditions are good, but this seems inefficient, and desert birds, in particular, may have other means of detecting areas where rain has fallen, responding perhaps to atmospheric pressure changes, cloud formations or changing odours. As yet, though, it remains a mystery how birds find widely separated patches of temporarily favourable habitat in the vastness of the desert.

Migratory flight

The reason that long-distance movements are so well developed in birds is that most species can fly. One of the main advantages of flight is its speed, which is much faster than the alternatives of walking, running or swimming. Flight requires more energy per unit time, but because of the greater distance covered, it is also the cheapest mode of transport overall. One type of flight, by soaring–gliding, is cheaper still, but is practised mainly by larger species, such as albatrosses, which can travel the Southern Ocean with little more energy expenditure than sitting still. Long-distance flight also allows birds to cross hostile areas that would otherwise act as barriers to their movements. Nevertheless, while most birds migrate by flying, penguins and some other seabirds migrate by swimming, and some landbirds by walking for part or all of their journeys.

The flight speeds of birds have often been measured using a car or airplane travelling alongside, or by using radar to track the movements of particular flocks or individuals (Bruderer & Boldt 2001). Measures taken from a vehicle or airplane cannot be corrected for wind effects, and are often of doubtful accuracy, so are of limited value. Radar measures can be obtained specifically for birds on migration and can be corrected to allow for wind speed, but do not always provide a reliable identification of species. Other values used for comparative purposes are the theoretical flight speeds calculated from aerodynamic principles on the basis of body mass, wingspan and wing area (Pennycuick 1969). The main findings to emerge from all these various sources of information are that, while individual birds can vary their flight speeds according to circumstance, larger birds generally fly faster than small ones, although body and wing structure also have a major influence.

Birds are assumed to migrate, whenever possible, either at their ‘minimum power speed’ (which minimises energy cost per unit time) or at their ‘maximum range speed’ (which minimises energy cost per unit distance). Both speeds are somewhat slower than the maximum speed of which the bird is capable. On average, 10 g birds have a theoretical maximum range speed in flapping flight of around 22 km per hour, 20 g birds of around 32 km per hour, 100 g birds of around 55 km per hour, 1000 g birds of around 85 km per hour and 10 kg birds of around 90 km per hour (Pennycuick 1969). As a rule of thumb, the theoretical maximum range speed of birds roughly doubles for every 100-fold increase in body mass up to around 15–20 kg, the approximate weight limit for flying birds. These are mean theoretical values, however, and species of similar weight would be expected to vary somewhat in their actual flight speeds, according to body and wing shape and other features, which differ from one type of bird to another. Hummingbirds, pigeons, ducks and auks fly faster than expected from their body weight, while terns, harriers and owls fly slower.

In steady flapping flight, a bird must generate the forces which support its weight against gravity and which at the same time provide the forward thrust necessary to overcome the friction and other forces that make up drag. The power for both the lift and forward thrust is supplied by the breast muscles, while directional control is provided mainly by the tail. Given sufficient fuel reserves, some birds that migrate by continuous flapping flight, such as passerines and waders, can travel for hours or days on end. They can cross water or other hostile terrain, and can fly by night as well as by day. In moving between their breeding and wintering places, therefore, such birds often travel directly, taking the shortest routes. As populations, they migrate mostly on a broad front, but concentrate to some extent through mountain passes or along coasts or other ‘leading-lines’ that deviate little from their main direction. Because flapping flight is expensive, however, such species must normally lay down substantial body reserves, especially for travelling over large areas of sea or other inhospitable substrate where they cannot feed. Sustained flapping also produces heat, which may enable birds to fly at high latitudes and altitudes without having to burn extra fuel to keep warm. In hot conditions, however, heat production can result in the need for evaporative cooling (panting), which increases water loss and dehydration risk.

The situation differs somewhat in birds that migrate mainly by soaring–gliding flight, notably the broad-winged raptors, storks and pelicans, which gain most of the energy they need for flight from the ambient atmosphere. Typically, these birds make use of updrafts created either by wind striking a cliff or slope being directed upwards, or by ‘thermals’, which are columns of rising air caused by uneven heating of the ground. Typically, soaring birds circle upwards in a thermal, then glide with loss of height to the next thermal and rise again; they repeat this process again and again along the migration route, and over long distances in ideal conditions they seldom need to flap their wings (Figure 4). Because the lift comes largely from rising air currents and the forward motion partly from gravity, this still-wing flight mode requires much less internally-generated energy than continuous flapping. Many soaring

Figure 4
Soaring–gliding bird migration, indicating soaring within thermals, gaining height, and gliding between thermals, losing height. Thermals are often topped with cumulus clouds.

species use a mix of gliding and powered flight, with intermediate costs, but seek to maximise the contribution from gliding, resorting increasingly to flapping as thermal conditions deteriorate. Flapping during a glide ('power gliding') can provide additional lift and speed, but at a cost in fuel use. The extreme soaring species thus depend for their movements mainly on a source of energy external to their own bodies, and unlike flapping birds, soaring species can continually correct for the effects of crosswinds without wasting energy.

Soaring-gliding flight has other consequences. Because of their dependence on updrafts, soaring landbird species must migrate mainly over land, favouring routes where appropriate conditions develop. They are also constrained to travel by day when the sun heats the land surface, creating rising air currents. Their migration typically reaches its peak, and moves most rapidly, in the middle part of each day when thermal activity is greatest. It is then that the birds achieve the greatest heights, and can make the longest and fastest glides across country (Spaar 1997, Spaar & Bruderer 1996). Soaring landbirds also tend to concentrate along narrow land bridges (such as Panama), or at narrow sea crossings (such as Gibraltar or the Bosphorus), and thereby avoid spending long periods over water where thermal soaring is seldom feasible. In this way, soaring landbirds often take long roundabout routes between breeding and wintering areas in order to make as much of their journey as possible over land, and minimise their use of expensive flapping flight. Despite the greater distances, their total energy consumption is thereby much reduced. Moreover, because their travel routes are determined by geography and topography, they tend to take the same traditional narrow-front 'corridor' routes year after year.

Soaring-gliding flight is not confined to landbirds. Many seabirds make use of up-currents formed either as the wind is deflected off waves (equivalent to slope soaring), or as a wave of 'swell' displaces air upwards as it moves over the sea surface. Some seabirds also use 'dynamic soaring', which depends partly on wind speed being slowed by the sea surface, an effect which is lessened with height up to about 16 m. The bird first climbs into the wind, then makes a high leeward turn, gaining distance by gliding with the wind whilst losing height. After making a low turn in the trough of a wave, it starts the cycle again. A bird could also make use of discontinuities in wind flow near the sea surface, as it flies first behind a wave crest and then emerges for a time into the unobstructed wind. At this moment, the bird tilts its body so that the temporary gust strikes its ventral surface, providing lift, enabling further onward gliding flight (Pennycuik 2002). Over most oceanic areas, soaring seabirds are normally constrained to fly low over the sea surface, where conditions are most favourable.

Migration mode

Some birds may benefit by migrating as rapidly as possible, thus minimising the time spent on travel (the 'time minimisation model' of Alerstam & Lindström 1990). Such birds would then gain the longest possible time on their breeding, wintering or moulting sites, but would require large fuel stores to permit long, non-stop flights. Other birds may have food available throughout their migration route, so that they can stop and feed almost anywhere. Because heavy fat loads mean greater transport costs, one way to save energy is to keep fuel loads small and fly only short distances at a time, refuelling as necessary (the 'energy minimisation' model). Moreover, because extra weight reduces flight performance (notably climb rate and agility), minimising fuel loads can also reduce predation risks (the 'predation minimisation' model). The second and third options may thus be combined as the 'load-minimising' strategy. The particular migration mode adopted by individuals in any population might be a compromise between any of these different options, depending partly on the type of terrain over which birds travel, the distribution of potential feeding sites, and the risks of predation. Moreover, any 'ideal strategy' that the bird might have is likely often to be compromised by external conditions, such as adverse weather or poor food supplies.

Difficult journeys

Landbirds that migrate over oceans provide some of the most extreme examples of endurance flight. They travel without opportunity to feed, drink or rest, over vast stretches of open water, where they cannot stop, as birds do overland, when the weather turns against them. Yet millions of landbirds regularly cross the Mediterranean Sea and the Gulf of Mexico at their widest points (about 1200 km), and smaller numbers regularly cross longer stretches, such as the western Atlantic between northeastern North America and northeastern South America (2400–3700 km), or the northern Pa-

cific between Alaska and Hawaii and other central Pacific Islands (5000–6000 km). To judge from their normal flight speeds, landbirds would take more than 100 hours of non-stop flight in still air to accomplish the longer of their overwater journeys, but by taking advantage of favourable winds, they can shorten their flight times, sometimes by as much as one half. Participants include many passerines and shorebirds, but also waterfowl which, unlike the others, can (and do) rest on the sea if need be. However, the most impressive of all overwater migrations by a landbird is undertaken by Bar-tailed Godwits (*Limosa lapponica*) from eastern Siberia and Alaska, which in autumn apparently accomplish an astonishing 175-hour non-stop 10,400 km flight to New Zealand (Gill *et al.* 2005). These figures are minima, and recent satellite-based radio-tracking of godwits has shown that both non-stop flight times and distances can be even longer.

Some overland journeys are also difficult. Long desert crossings are made by the many species (including passerines) that travel between Eurasia and tropical Africa (Moreau 1961). Most west European species cross at least 1500 km of the Sahara Desert immediately after crossing the Mediterranean Sea. In autumn some species may make this Mediterranean–Saharan flight without a break, a total journey of 1500–2700 km, depending on the route taken. Other individuals on the same journey fly by night but stop and rest in the shade by day, but without feeding or drinking (Biebach 1990). Yet other birds from further east cross the central Asian deserts, and then another 1700 km of southern Arabia and its bordering gulfs, before reaching East Africa. In Australia, some shorebirds cross the central desert in moving between southeast and northwest coasts, a journey of more than 2000 km.

Yet other birds cross high mountain ranges, including the Himalayas and Tibetan plateau. One such species is the Bar-headed Goose (*Anser indicus*) which in the process can rise to more than 8 km above sea level, where the air is thin and very cold. Other species cross extensive areas of pack-ice that lie in spring between Siberia and Alaska or between Norway and Svalbard. A few species cross 2000 km of the 2-km-high Greenland ice cap on journeys between northeastern Canada and western Europe.

Seabirds migrating entirely over the sea would seem to have plenty of opportunity to pick up food en route. But this is not always the case. Many species breeding at high latitudes migrate over the equator, and tropical seas are notoriously poor in food. In any case, foods such as surface fish tend to be concentrated in particular nutrient-rich places, which may be few and far between. Evidence is accumulating that, like some landbirds, some seabirds refuel at widely-separated staging areas before continuing migration. For example, after breeding in western Europe, Black Terns (*Chlidonias niger*) assemble at one major feeding area, the IJsselmeer on the Dutch coast. Here they increase in body mass by 25–30% within 2–3 weeks, which would then enable a non-stop flight of more than 3600 km to West Africa. The birds ascend in the evening to more than 500 m and start migration at night. Although Black Terns are seen at localities en route, no important stopover site is known between the IJsselmeer and West Africa (van der Winden 2002). In Namibia, a similar increase in the body mass of Black Terns was noticed prior to spring migration.

Duration and speed of migration

It is not so much the speed of flight that determines the speed of migration, but the time spent on stopovers where fuel reserves are replenished. Migration speed is a function of both flight times and stopover times. From knowledge of the average fuelling rates and flight costs of small passerines, it has been calculated that, for every hour spent in flight, about seven hours would need to be spent on the ground, feeding and resting (Hedenström & Ålerstam 1998). Such a ratio has been borne out by field observations. In larger birds which refuel at a slower rate, the proportion of stopover time is two to three times greater than in passerines (Newton 2008).

Actual migration speeds have been measured mainly by use of ring recoveries of birds identified at different points on their migration routes, or in recent years from the satellite tracking of radio-marked individuals or other electronic means. Such studies have revealed that the times spent on migration by different bird populations are enormously variable, depending partly on features of the birds themselves (such as body size, wing shape and flight speed), but largely on the distances travelled and the conditions encountered en route. At one extreme, some birds can complete their migration in less than one day (such as a radio-tagged Bald Eagle (*Haliaeetus leucocephalus*) that flew 435 km between its wintering site in Michigan and its nesting place in Ontario, Grubb *et al.* 1994). At the other extreme, some landbirds take at least four months to reach their distant winter quarters, and at least two months to return, so that more than half of every year is spent on migration. Long journey times are also shown by some

marine species, including shearwaters and petrels, which have a fixed base only during the breeding season, and are effectively on migration for the rest of the year, pausing to feed at places where food is available en route. Whatever the advantages in migrating as quickly as possible, external conditions provide severe constraints, notably the rate at which food can be obtained and converted into body reserves to fuel the flights, and also the weather at the time, which could speed or slow the journeys. Rain or snow, cold or ice, or unfavourable winds can delay migration for days or weeks at a time.

We should not be misled by birds that make their whole over-sea migration in one flight. In favourable winds, wild geese have been found to fly 5000 km over water within 60 hours, giving mean speeds of around 2000 km per 24-hour day, or around 80 km per hour. Bar-tailed Godwits travelling from Alaska to New Zealand covered more than 10,400 km non-stop in seven days, around 1500 km per day, or 60 km per hour (Gill *et al.* 2005). However, these estimates exclude the initial fuelling period, which could extend to several weeks, considering the large fuel reserves necessary to power such long over-water flights. Strictly speaking, fuelling times are part of migration, and should be added to flight times. These record speeds would then not seem so unusual.

Weather effects on migration

Weather has obvious effects on bird migration. It influences the times when birds can travel, the energy costs and risks of the journey, and the visibility of any celestial or ground-based cues that birds might use for navigation. Yet assessing the effects of weather on the volume of bird migration is not straightforward. This is partly because migration depends less on the prevailing weather than on the intrinsic migratory state of the birds themselves. The numbers of individuals migrating on particular days depend not just on the prevailing weather, but on the weather over preceding days, the date in the season, and the proportion ready to leave at the time. Towards the end of the migration season few birds may be left to migrate, however good the weather. The association between the volume of migration on particular days and the prevailing weather is therefore not constant, which complicates analysis. In addition, because species differ in body size, flight mode and other aspects, they are affected by adverse weather to different extents, some species being able to travel in conditions that would ground others (Alerstam 1978, Lack 1960).

Another problem is that different weather factors tend to be associated with one another, with some occurring under cyclonic and others under anticyclonic conditions (Lack 1960, Richardson, W.J. 1990). Even with the help of multivariate statistics, it is often hard to tell which factors are critical to migration and which are coincidental. Almost certainly, migrants do not react to the general weather situation as such, but to one or more components of it, such as wind and rain. Nevertheless, for the human observer, the synoptic weather situation of fronts and pressure systems gives a good indication of how much migration is likely to occur at different places on particular days.

Visual records from ground-based observers armed only with binoculars may miss birds flying too high to be seen by day, and provide little or no information on nocturnal migration. Yet radar has revealed that most migration of birds that fly by flapping flight occurs above binocular range. In fact, the proportion of birds flying within sight, and the proportion that come to ground, tend to be greatest in conditions that are unfavourable for flight (Lack 1960). Thus, migrants tend to fly low in opposing rather than following winds, and to settle whenever they encounter strong opposing winds, mist or rain, or reach coastlines or islands. The observer equipped only with binoculars might conclude that these were the very conditions that favoured migration, a once firmly held view but the opposite to reality. Birds also tend to fly low along coasts in these conditions, reluctant to strike out over water. It is therefore important to distinguish the influence of weather in promoting migration from its influence in making migration conspicuous (Alerstam 1978, Lack 1960).

The advent of radar greatly clarified the situation, because it enabled migrants to be detected at almost all heights (missing only those below the radar horizon), day and night, and in all weathers. From radar-based studies, consensus has now emerged that, within the appropriate seasons, migration is favoured by fine anticyclonic conditions with favourable tailwinds, and also by rising temperatures in spring and by falling temperatures in autumn. In effect, at both seasons the birds prefer to migrate under clear skies with following or light winds. Clear skies assist navigation, especially at night, by making celestial cues more visible, while following winds reduce the time and energy spent on the journey, and the risk of being blown off course. In contrast, birds seldom take off to migrate in strong opposing winds, dense cloud, mist and rain. Opposing winds make progress difficult or impossible, cloud hampers navigation, while mist or rain can soak many kinds of birds and force them down.

While temperature is important to migration, the basis of this relationship is less clear. In spring, warmth occurs in association with other conditions favourable to flight, as does cold in autumn. But temperature may have direct effects through influencing the energy balance of the birds, and more importantly through influencing their food supplies, because all vegetative growth, insect activity, and ice melt are temperature-dependent. It is therefore of obvious advantage for migrants to adjust their migratory schedules to year-to-year variations in temperature, and they are clearly deterred in spring by extreme cold and snow.

If migrating birds meet low cloud and unfavourable wind en route, they may be forced low and, if over land, they can settle and wait for conditions to improve. Over the sea, as radar has revealed, landbird migrants that enter cloud or mist banks often become disorientated, milling in all directions and gradually drifting downwind, or actively flying downwind which gives a good chance of reaching clearer weather (Lack 1960, Richardson, W.J. 1990). If cloud persists, migrants over the sea are sometimes attracted in large numbers to lighted ships or oilrigs (Bourne 1979). Although heavy overcast appears inimical for migration, some birds seem to maintain more or less straight courses with complete cloud cover. Below the cloud they can see the ground, and above it the sun or stars (although flying above the cloud seems infrequent).

Importance of wind

In general, wind speeds are stronger at mid-day than at night or early morning, and increase from the ground, where friction slows the flow, up to several thousand metres. In addition, the air mass in which birds migrate is continually changing in speed and direction, and birds must continually adjust their behaviour if they are to migrate to a predetermined destination in the most energy-efficient way. That birds respond to wind is shown by the frequent observations that: (1) they tend to depart only in favourable (following) winds; (2) they often select flight altitudes where winds are favourable; and (3) they compensate for wind drift, at least to some extent, providing that they can see the ground below.

Wind assistance is like food or fat reserves: it is a resource that fuels migration. If a bird with a given flying speed was blessed with a tailwind of the same direction and speed, it could in theory fly twice as far on the same fuel and in the same time, or the same distance on half the fuel and in half the time. Yet a bird flying into a headwind of the same speed could make little or no progress, however great its fuel reserve. In practice, it seems from radar studies that birds flying overland do not behave in quite this way, but fly slower than usual with a tailwind, and faster than usual against a headwind (Alerstam & Gudmundsson 1999, Hedenström *et al.* 2005, Liechti 2006). It is as though they conserve energy when conditions allow, and expend more than usual when necessary. The net effect is that birds make slower progress than expected in a tailwind, and faster progress than expected in a headwind, but further study is needed to find how widespread this behaviour is. In any case, following winds reduce the energy cost of migration, which is important to many migrants.

If the wind blows from the side, the bird can in theory correct for this by adjusting its heading so as to remain on track with respect to the ground (Figure 5). Birds do not then progress in the direction they are heading, but at some angle to it, which is closer to the intended track. The greater the crosswind component for a given flight speed, the greater this compensating angle must be (aircraft pilots refer to the angle between heading and track as the drift angle, *alpha*). This angle can be reduced if the bird flies faster. The point at which a bird is no longer able to compensate for lateral drift is thus a function of wind speed and direction, as well as the maximum flight speed that the bird itself is able to maintain (called the threshold for drift, Evans 1966).

Radar observations have been used to explore not only the extent to which migrating birds can compensate for drift by crosswinds, but also how much the prevailing circumstances (wind strength, visibility, day or night, over land or over sea, and cloud cover) affect the response. Patterns of compensation, full lateral drift, partial drift and downwind drift have all been observed, depending on conditions. Birds can presumably 'know' they are being drifted off course only when they have reference to some stable feature, such as the ground below; for drift would have to be substantial before it could be detected from celestial or magnetic cues. These considerations may explain why compensation seems usual in low-altitude (<1 km) diurnal migrants, but is much less frequent or complete at high altitudes, and why it is more frequent in light winds (up to 5 m per second) than in stronger ones (Bruderer & Jenni 1990). In any case, it is rarely complete in nocturnal migrants and over large water bodies (Richardson, W.J. 1990). Drift by crosswinds is, of course, one of the commonest ways in which migrants turn up as vagrants in places off their normal routes.

Figure 5
Diagram showing relationships between heading (H , the direction the bird faces), wind direction (W), and track (T , direction the bird travels on a journey). The track vector (T) is the sum of the heading (H) and wind (W) vectors. The angle α between track and heading depicts the amount of drift with constant heading, while the angle β shows the wind direction in relation to the track direction.

With respect to wind, soaring birds provide a partial exception to the usual patterns. Updrafts strongly reduce the energy cost of migration for such birds, which often fly in side-winds or light opposing winds if updrafts are present. Thermals develop in calm or light wind conditions, but not in strong winds, which suppresses soaring bird migration in some regions, regardless of wind direction. Soaring birds also show no particular tendency to migrate on cold days in autumn, as do many other birds, probably because the necessary thermals develop best on warm days (Alerstam 1978, Kerlinger 1989).

Flight altitudes

As revealed mainly by radar studies, the altitude of migratory flight is related to prevailing atmospheric conditions, especially wind speed and direction, but also cloud thickness and height, topography and other factors, as well as features of the birds themselves. Over low land, most migration takes place within 1.5 km of the ground, with decreasing numbers of birds at higher altitudes up to 3 km or more (Bruderer 1999). When birds need to cross high mountains or find favourable airstreams, they sometimes fly much higher, occasionally reaching more than 7 km.

Several species migrate regularly over the Himalayas, and as mentioned above, at least one species, the Bar-headed Goose, has been recorded at more than 8 km above sea level. Some birds can thus achieve feats of high altitude performance unmatched by other animals, and can do so without needing time to acclimatise. Clearly, they must be pre-equipped physiologically to avoid altitude sickness (hypoxia). Not all birds have such flexibility in their flight altitudes and, whatever the advantages of high-altitude flight, some species (such as swans) seem confined to migrate at low elevations, presumably for physiological or energy-based reasons (one published high altitude estimate for swans probably being erroneous).

Soaring birds are limited in flight altitude by the height reached by thermals, which is greatest around noon over land, and in most conditions seldom exceeds 1.5 km. During their migrations, soaring birds are continually rising and falling, as they climb in successive thermals and lose height between them (Leshem & Yom-Tov 1996b, Spaar & Bruderer 1996). Unlike many other birds, therefore, soaring species cannot maintain constant altitude over long distances.

Diurnal and nocturnal migration

As indicated already, some birds migrate mainly by day and others mainly by night. Nocturnal species such as owls and nightjars, or optional diurnal–nocturnal species such as shorebirds, might be expected to migrate under cover of darkness. Surprisingly, however, many normally diurnal species also prefer to travel at night. To judge from their eye structure, diurnal birds may have no better vision at night than do humans, but this would still enable them to fly safely through the open skies, and recognise star patterns and landscape features that might help them find their way.

Apart from soaring landbirds, which depend on daytime thermals, it is not immediately obvious why particular species migrate at one time rather than another. Among passerines: crows, finches, pipits, larks, wagtails, tits, swallows and others migrate primarily by day; while warblers, flycatchers, thrushes, chats and others migrate primarily by night. Among non-passerines: pigeons, raptors, cranes, herons and egrets migrate by day; while cuckoos, shorebirds, rails, and grebes migrate mainly by night. Comparing different families, there is no obvious and consistent connection between migration times and difficulty of journey, habitat, diet or other aspects of ecology. Among closely-related families, some striking differences occur, as in the passerines just mentioned, and also among waders, in which plovers (*Charadriidae*) migrate more by day than sandpipers (*Scolopacidae*). Although most species within a family seem consistent in their migratory behaviour, occasional revealing exceptions occur, with the tendency to nocturnal migration increasing with migration distance (Dorka 1966). For example, most species of *Emberiza* buntings in western Europe migrate by day over short distances, but the Ortolan Bunting (*E. hortulana*) migrates by night over long distances, being the only species that winters in Africa south of the Sahara. Similarly, most pigeons migrate by day over short distances within Europe, but the European Turtle-dove (*Streptopelia turtur*) migrates partly by night over long distances to Africa. In addition, Tree Pipits (*Anthus trivialis*) are more nocturnal than Meadow Pipits (*A. pratensis*), Willow Warblers (*Phylloscopus trochilus*) than Common Chiffchaffs (*P. collybita*), and Common Redstarts (*Phoenicurus phoenicurus*) than Black Redstarts (*P. ochrurus*). In all these species pairs, the first mentioned migrates

further than the second. Nevertheless, there are still some puzzling exceptions: for example, European Robins (*Erithaca rubecula*) and Common Firecrests (*Regulus ignicapilla*) are short-distance migrants, but still travel mainly at night.

The division between day and night migrants is most obvious from take-off times, with diurnal migrants leaving mainly in the morning and nocturnal ones mainly in the evening. However, whether day or night, landbirds of both groups must continue flying if they find themselves over water, as must waders and waterfowl over dry land.

The main supposed advantages of nocturnal migration are that: (1) more time is left for feeding during the day, the only time that most birds can feed, so the entire journey can be accomplished more quickly; (2) temperatures are lower at night than in the day which could help to prevent over-heating and dehydration in warm regions; (3) humidities are usually higher at night and early morning, which could further reduce dehydration risk; (4) energy demands are lower, because it costs less to fly in cooler denser night air than in warmer daytime air; (5) wind speeds are generally lower at night, thus reducing the effects of headwinds or crosswinds, and vertical turbulence is less, further reducing the total energy costs of flight; (6) the use of stars for navigating is possible; and (7) the likelihood of predation during flight is much reduced. The main threat to flying migrants is from falcons or eagles during the daytime (plus gulls over water), but a wide range of other raptors take migrants when they are on the ground. Owls do not normally fly high enough to encounter migrants and in any case seldom catch prey on the wing. Given these advantages, it is surprising that any birds (apart from thermal-dependent soaring species) migrate by day.

Control of migration

In considering the timing of migration, it is helpful to separate the ultimate from the proximate causal factors. The ultimate factors, notably seasonal changes in food supplies, are those that act through the survival and reproduction of individuals, favouring those genotypes which migrate in spring in time to take advantage of optimal conditions for breeding, but leave in autumn before their continual survival in breeding areas would become precarious. The proximate factors are those, such as changing daylengths, which act to trigger migration at appropriate dates each year. The birds may thus be said to migrate in spring because they can then take advantage of a developing food supply in breeding areas (the ultimate cause) or because they are stimulated to do so by increasing daylengths and other prevailing conditions (the proximate cause).

As every bird-watcher can see for himself, many long-distance bird migrants arrive at their nesting or wintering places every year at around the same dates. This implies the existence in the birds of precise timing mechanisms that, in response to external stimuli, trigger migration at about the same dates each year and maintain it for long enough to allow the bird to cover the distance required. The relatively small differences in timing that occur from year to year are mainly associated with variations in prevailing weather or food supplies.

In the scientific literature dealing with the timing of bird migration, German words are often used, even in texts written in English or other languages. This custom persists from a time when Germany led the world in migration research, mainly in the first few decades of the 20th century, when many of the basic concepts and paradigms were laid down. Anyone who reads widely in this subject area can thus expect to come across words like *Zugdisposition* (readiness to migrate), *Zugunruhe* (migratory restlessness), and *Zeitgeber* (time keeper).

The migratory state

Migratory condition (*Zugdisposition*) in birds is marked by a sudden weight increase, due largely to the deposition of additional fat which serves as the main fuel during the journey. In captive birds, it is also marked by the development of so-called 'migratory restlessness' (*Zugunruhe*). This is a distinct form of behaviour in which birds hop and flutter round their cages, and undertake long periods of 'wing-whirring' in a perched position (perhaps equivalent to migration in a cage). Typical diurnal migrants show this behaviour by day, and nocturnal ones by night. It gives a useful indication of migratory condition in captive birds because it can be quantified automatically. From studies of body weight and restlessness in caged birds, much has been learned about the proximate control of migration. Under natural daylengths, caged birds from migratory populations develop fat reserves and migratory restlessness at appropriate dates in autumn and spring, at about the same times as their wild counterparts (Berthold 1996, Gwinner 1986).

Endogenous rhythms

While the ultimate extrinsic factor controlling the annual cycles of birds is the seasonality of the environment, the primary intrinsic proximate factor is apparently an endogenous rhythm within the bird. This self-sustaining rhythm tends to ensure that the major processes of migration, breeding and moult occur in the correct sequence each year, and at roughly the right times. The evidence for the existence of an internal rhythm has come largely from studies on captive birds kept for up to several years under rather specific but constant daylengths (Berthold 1996, Berthold & Terrill 1991, Gwinner 1968, 1986, 1996, Gwinner & Helm 2003). Such birds have no clue from the outside world as to what the date might be. Yet they usually moult and reach breeding and migratory condition in the correct sequence, and at roughly appropriate intervals, with corresponding cycles in body weights, gonad sizes and hormone levels. This finding is taken to imply the existence of some underlying 'endogenous' controlling system. However, in conditions of constant daylength, the cycles do not stick strictly to a year, but tend to drift, getting either shorter (rarely) or longer, hence the term 'circannual' cycles, which typically last 9–13 months.

The existence of internal circannual rhythms, underlying the natural yearly cycles, and persisting for at least two cycles, has now been shown experimentally in more than 20 different bird species, including resident and migratory, temperate and tropical, passerines and non-passerines, as well as in other animals and plants (Berthold & Terrill 1991, Gwinner 1981, 1986, 1996). Circannual rhythms evidently underlie the control of seasonal activities in a great variety of organisms. Among birds, circannual cycles may be reflected in gonad condition alone, in moult alone, in migratory condition alone, or in any combination of these activities. The cycles can thus be viewed as consisting of separate but integrated components involving the different activities (Wingfield 2005). Which of these components are expressed in captive birds depends largely on the constant photoperiod to which the birds are exposed, and perhaps also on the time of year (= internal physiological state of the birds) when the experiment starts.

Spontaneous endogenous rhythms are most apparent in long-distance migrants, which are normally exposed to varying photoperiodic regimes on migration, and in which the need for some form of endogenous control is greatest. They are also apparent in some resident species of equatorial regions, where daylengths are constant year-round. For example, equatorial Common Stonechats (*Saxicola torquata axillaris*) kept caged in Germany under constant 11.8 hours of light alternating with 11.2 hours of dark went through up to 12 reproductive-moult cycles in a 10-year period (Gwinner 1996). However, in temperate zone residents and short-distance migrants caged in constant conditions, the cycles tend to continue for less long, and are more variable among individuals; they seldom proceed for more than one year, and the different events tend to become increasingly out of phase with one another. They are thus less rigid and persistent, as found in some Blackcap (*Sylvia atricapilla*) populations (Berthold *et al.* 1972) and in Common Stonechats (*S. t. rubicola*) from Europe, as opposed to Africa (Gwinner 1996).

The role of daylength

Under natural conditions, the endogenous cycles of many birds are kept in phase by seasonal daylength changes, and in experimental conditions particular events can be advanced or retarded by appropriate use of an electric light (Farner & Follett 1966, Lofts & Murton 1968). For example, if migratory birds of some species are exposed in late winter to photoperiods longer than natural days, their gonads begin to grow earlier than usual, and they show migratory and reproductive behaviour prematurely (King 1972, Lofts *et al.* 1963, Rowan 1925, Wolfson 1959). Similarly, if they are exposed in late summer to shorter days than usual, they moult and reach migratory condition earlier than usual.

The importance of daylength as a time-keeper (*Zeitgeber*) derives from its reliability. Its seasonal changes are consistent between years, making it the most obvious environmental feature that, at most latitudes, gives a reliable cue to date. The synchronisation of the internal annual cycle to photoperiod has been shown most convincingly in experiments in which birds were exposed to seasonal photoperiodic cycles with periods deviating from 12 months (e.g. six month cycles). As a rule, the birds' biological rhythms then conformed to the altered photoperiodic regime (Gwinner 1986, 1990b). For example, when the normal annual cycle of daylength was shortened to six months without altering its amplitude, Garden Warblers (*Sylvia borin*) went through four instead of two moult periods within one calendar year, two instead of one gonad

Figure 6
Relationship between the usual distance migrated and the number of nights that captive juveniles showed migratory restlessness for different populations of *Sylvia* warblers. The longer the journey undertaken by wild birds, the more nights of migratory restlessness were shown by captive birds from the same population. From Berthold (1973).

cycle, and four instead of two periods of migratory restlessness (Berthold 1996). The same occurred in Sardinian Warblers (*Sylvia melanocephala*), in which the usual one annual moult occurred twice within one calendar year (six months apart). It also occurred in Common Stonechats which underwent two gonad and moult cycles in one calendar year (Gwinner & Helm 2003). More remarkably, Dark-eyed Juncos (*Junco hyemalis*), which were exposed to four periods of short (9-hour) days and five periods of long (20-hour) days in one year, showed in this time five periods of gonadal activity, five of fat deposition and two of moult (Wolfson 1954).

Time and distance programmes

In general, the longer the distance between breeding and wintering areas, the greater is the duration and intensity of migratory restlessness (*Zugunruhe*) shown by caged birds. Different *Sylvia* warblers that breed in Europe migrate average distances varying from a few hundred to nearly six thousand kilometres, and show corresponding average periods of restlessness varying from less than twenty to more than 1000 hours (Figure 6). This implies that periods of restlessness in these different populations are endogenously (genetically) determined. In addition, the amount of fat accumulated by captive birds at migration times is related to the types of journeys they make in the wild. Birds that migrate by long flights, as from Europe to sub-Saharan Africa, typically accumulate more fat in captivity than do birds that migrate short distances within Europe (Berthold 1973, 1984). This contrast is evident in comparisons between related species, such as Willow Warbler and Common Chiffchaff (Gwinner 1972), and between different populations of the same species which migrate different distances, as in the Blackcap (Berthold & Querner 1981). Hybrids between short-distance and long-distance populations of the Blackcap show intermediate patterns of restlessness and fattening (Berthold & Querner 1981).

Directions

The timing and duration of migratory restlessness, and patterns of fattening, are not the only features under endogenous control, as the same applies to directions. Birds from populations that take different directions in the wild show the same directional preferences when tested in captivity in special 'orientation cages'. These circular test cages have a wire top, so the bird can see the sky, and some system of automatic recording which indicates the directional preference adopted by the bird during periods of restlessness.

Blackcaps in western Europe mostly migrate southwest in autumn, while those from eastern Europe migrate southeast, the two types separated by a distinct 'migratory divide'. Birds from the two types, reared together in captivity and then tested in orientation cages, showed appropriate directional preferences, either southwest or southeast, depending on their region of origin (Helbig 1991). Moreover, hybrids between the two types showed intermediate directional preferences, more or less due south. These and other findings provide strong evidence that directional preferences are inherent, and endogenously controlled.

Some wild migrants in spring retrace their path from the previous autumn, but others take different routes at the two seasons (so-called loop migrants). When tested for directional preferences in orientation cages, hand-reared Garden Warblers kept in constant (12Light:12Dark) conditions changed their mean heading from southwest to southeast part way through their autumn migration period. This corresponded with a change they would normally make part way through their journey between central Europe and Africa (Gwinner & Wiltshko 1978). They made no such change in spring, when they return by a more direct northerly route, requiring no change in direction during the journey. This gave another indication that directional preferences were endogenously controlled, and that spring directions were not simply the reverse of autumn ones.

Integration of time-distance and direction programmes

The combination of inherent time-distance programmes and directional preferences could explain how juvenile birds migrating on their own can reach wintering areas unknown to them but specific to their population. On this basis, naïve autumn migrants would fly in the right direction for an appropriate period, and would not need to experience the particular conditions of their wintering areas before they stopped mi-

grating. After an appropriate time, caged birds from both European and North American breeding areas lost their autumn restlessness and fat reserves, even though they had moved no further than the confines of their cages. Moreover, when captive juveniles were experimentally transported to their species-specific wintering areas, or even beyond their normal wintering range, the migratory activity they showed in cages persisted as long as that of individuals kept in the breeding area (for experiments on young Garden Warblers, Lesser Whitethroats (*Sylvia curruca*) and European Pied Flycatchers (*Ficedula hypoleuca*) see Gwinner 1971, Rabøl 1993). Similarly, juvenile Common Starlings and other species that were trapped on migration, flown by airplane and released immediately in the usual wintering areas for their population, or at some other locality off the normal route, resumed migration. Ring recoveries revealed that these transported juveniles moved in the same direction and covered about the same additional distance that they would have travelled had they not been displaced (Figure 7; Perdeck 1964, 1967). These experiments again suggested control of timing and direction by an endogenous programme, rather than by location. This type of migration is often called 'clock-and-compass' or 'vector' migration.

The role of experience

On current thinking, then, the urge to migrate in autumn and spring is genetically controlled. It is reflected in an autonomous rhythm of physiology and behaviour, which is kept on schedule by daylength changes (Berthold 1996, Gwinner 1972, 1986). This inherent system controls both fattening and migratory restlessness, as well as the general direction and time-course of migration. However, most of the experimental work which gave rise to these ideas was based on naïve juvenile birds that had no previous knowledge of the wintering range of their population. The situation differs somewhat in experienced birds migrating to a known site. This was first shown in experiments with Common Starlings and others, in which adults birds displaced off their normal route did not stick to their inherent direction, like the juveniles described above, but corrected for their displacement, changed direction and headed back to their previous wintering areas (Figure 7). These birds revealed more than one-directional orientation; they had a map sense, as they knew where they ought to be, and headed towards their goal (Perdeck 1958). On return migration to breeding areas, both juveniles and adults proved able to return to the region of their birth, but in this case both age-groups had previous experience of the area (Perdeck 1958).

Later experiments on Dark-eyed Juncos showed that individuals that were held captive on their wintering areas all summer did not show the usual autumn restlessness and fattening. Many of those that were released in autumn in wintering areas stayed nearby, often within the same home range they occupied the previous winter (Ketterson & Nolan 1986). They acted as though they knew where they ought to be at that time of year, and remained there without migrating. However, they disappeared from the area in the following spring and some reappeared in the next autumn, so they were assumed to have spent the summer as normal on more northern breeding areas.

Comparable findings emerged from an experiment in which migratory Indigo Buntings (*Passerina cyanea*) were held in their breeding areas through the winter, and released there in spring (Ketterson & Nolan 1990, Sniegowski *et al.* 1988). Seven out of 20 males released in spring in their nesting territories remained, while eight out of 20 that were transported and released 1000 km to the south returned to their nesting localities. The remaining birds were unaccounted for, but it seemed that when migrants were exposed in spring to their previous nesting place, they did not migrate. These findings gave a further indication that the inherent template of migration, so important to the first migration of juveniles, could be modified by experience.

Other factors influencing the timing of migration

Within the migration season, migratory flights may be influenced by prevailing weather, as discussed earlier, and also by food supply. The role of feeding conditions in affecting autumn fattening rates, body condition and departure dates has been established in the field for a number of species ranging from the Sedge Warbler (*Acrocephalus schoenobaenus*), studied by Bibby & Green (1981), to the Greylag Goose (*Anser anser*), studied by van Eerden *et al.* (1991).

When they reach an appropriate weight, migrants normally leave immediately if weather permits. This would be expected because, once acquired, fat reserves are dangerous and expensive to maintain, conferring increased vulnerability to predation. For example, when captive Blackcaps were exposed to simulated predator at-

Figure 7

Displacement experiment performed on Common Starlings which were caught while on migration through the Netherlands, and then displaced to the south and released. Juveniles migrated in the same direction and for the same distance as they normally would, following a route parallel to their usual route, while adults corrected for their displacement, and headed northwest towards their normal wintering area. The juveniles had never previously experienced the normal wintering area, whereas adults 'homed' to the area they had experienced in previous years. From Perdeck (1958).

tacks, individuals carrying a fuel load equivalent to 60% of lean body mass (the maximum recorded in this species) were calculated to suffer reduction of 32% in angle of ascent and 17% in velocity, compared to lean Blackcaps (Kullberg *et al.* 1996). This degree of difference could put fat birds at substantially greater risk. Research on captive birds, or on wild ones caught during migration, has confirmed that the motivation to proceed with migration is related to fat reserves, as is the strength of directional preference. In general, individuals with the greatest body reserves at any one time showed the greatest migratory restlessness and the strongest directional preferences (Bairlein 1992, Berthold 1996, Dolnik & Blyumental 1967, Sandberg *et al.* 2002, Yong & Moore 1993).

Autumn migration

Migrants normally leave their breeding areas when conditions deteriorate, but before their continued survival there would become precarious. From any one area, however, departure dates also differ widely between species, between late summer and late autumn, depending largely on their type of food and when it becomes scarce. For example, species that depend on insects from fresh leaves, such as warblers, normally leave before those that depend on fruit or seeds, such as thrushes and finches. Moreover, in association with the earlier onset of winter at high latitudes, many species withdraw from high-latitude parts of their breeding range first, and from lower latitude parts later. The assumption is that, in order to prepare for autumn migration, populations have evolved responses to different daylength regimes, appropriate to the latitude at which they breed.

Obligate and facultative modes

In considering the proximate control of autumn migration, a useful distinction can be drawn between obligate migrants (formerly called 'instinct' or 'calendar' migrants), and facultative migrants (formerly called 'weather' migrants). In obligate migrants, all main aspects are viewed as under firm internal (genetic) control, mediated by daylength changes, which gives a high degree of annual consistency in the timing, directions and distances of movements. For the most part, each individual behaves in the same way year after year, migrating at similar dates and for similar distances. Obligate migrants often leave their breeding areas well before food supplies collapse, and while they still have ample opportunity to accumulate body reserves for the journey. They tend to migrate long distances, often to the tropics or beyond. Examples include swallows and warblers.

In contrast, facultative migration is viewed as a direct response to prevailing conditions, especially food supplies, and the same individual may migrate in some years but not in others. Within a population, the proportions of individuals that leave the breeding range, the dates they leave and the distances they travel, can vary greatly from year to year, as can the rate of progress on migration, all depending on conditions at the time (e.g. Moore *et al.* 2003, Newton 2006, Svårdson 1957, Terrill 1990). In consequence, facultative migrants have been seen on migration at almost any date in the non-breeding season (at least into January in the northern hemisphere), and their winter distributions can vary greatly from year to year. Extreme examples include irruptive seed-eaters, such as Common Redpoll, Eurasian Siskin (*Carduelis spinus*) and Bohemian Waxwing (*Bombicilla garrulus*). Although in such facultative migrants, the timing and distance of autumn movements may vary with individual circumstances, other aspects must presumably be under firmer genetic control, notably the directional preferences and the tendency to return at appropriate dates in spring.

Compared with obligate migrants, facultative migrants tend to migrate shorter distances, although many exceptions occur. The two types of migrants thus have different distribution patterns in mid winter. Whereas obligate migrants are concentrated in a distinct wintering area, usually at long distance from the breeding area, facultative migrants are typically found over the whole migration route from breeding to wintering areas, usually tailing off with increasing distance from breeding area, but with marked annual variations.

In general, it seems that obligate migration occurs in populations whose food supplies in breeding areas are predictably absent in winter, whereas facultative migration occurs in populations whose food supplies in breeding areas vary greatly from one winter to another, according to weather or other variables. The distinction between the two types is thought to reflect the degree to which individual behaviour is sensitive to prevailing external conditions, and hence varies from year to year. However, obligate

and facultative migrants are best regarded, not as distinct categories, but as opposite ends of a continuum, with predominantly internal control (= rigidity) at one end and predominantly external control (= flexibility) at the other.

Another reason for not drawing a sharp distinction between the two categories is that many birds seem to change from obligate to facultative mode during the course of their journeys, as the endogenous drive to migrate wanes with time and distance, and the stimulus to continue becomes more directly dependent on prevailing local conditions (Helms 1963, Terrill 1990, Terrill & Ohmart 1984). Theoretically, the initial obligate phase of any journey might take the migrant across regions where the probability of overwinter survival is practically zero: where any individuals that attempted to winter there in the past were eliminated by natural selection. As migration continues into more benign areas, and survival probability increases, the bird switches to a facultative mode, in which it benefits by responding to local conditions, stopping where food is abundant. The obligate phase would therefore be expected to be undertaken much more rapidly, on average, than the facultative phase, which involves longer and more variable stops. Such a two-phase migration, with obligate and facultative stages, would also ensure that, in any particular year, the bird migrated no further than necessary. In some species only the tail end of the migration may be facultative, in others the entire journey. Most irruptive migrants are near the latter end of the spectrum.

Arctic-nesting geese provide circumstantial evidence for a two-phase migration, in which the first part is obligatory and the second part facultative. Geese need to leave the arctic every year before survival there becomes impossible, and they tend to depart en masse on about the same dates every year. But once they reach suitable wintering areas, their movements become much more variable in timing and extent, depending on local food availability. They appear to change from a primarily endogenous migratory phase (obligate migration) to a stage when the stimulus for further migration is primarily environmental. In effect, as birds travel south in autumn, the drive to continue becomes increasingly dependent on food and other local conditions.

Role of dominance in facultative migrants

Because birds compete for food, and vary in dominance or feeding efficiency, some individuals could survive in conditions where others would die unless they moved out. In facultative migrants, the subordinate sex and age groups typically migrate in greater proportions, at earlier dates, or extend further from the breeding areas, than the dominants. Thus, in many bird species, adult females are more migratory than adult males, juveniles more than adults, and late-hatched young more than early-hatched ones (Gauthreaux 1982, Smith & Nilsson 1987). Such differences have led to the notion that, in facultative migrants, competition (or its effect on body condition) is involved as a proximate mechanism stimulating migration in those individuals least able to survive in local conditions (Gauthreaux 1982).

Timing of autumn migration

In obligate migrants, where all individuals leave the breeding range each autumn, the dates of migration are in general fairly consistent from year to year. This is apparent not only in the dates that birds leave their breeding areas, but also in the dates they pass particular places on their migration routes and arrive in wintering areas. For example, among raptors migrating through Israel en route to Africa, the timing and duration of passage varied greatly between species, but within species the autumn passage dates were remarkably similar between years (as were spring dates). Over nine years, the confidence intervals of the mean autumn dates ranged between 1.5 and 3.4 days (versus 2.1–5.5 days for spring dates), depending on species (Leshem & Yom-Tov 1996a).

In facultative migrants the situation differs. Such populations generally moult after breeding and, in contrast to obligate migrants, individuals do not necessarily depart immediately after finishing moult. If conditions are favourable, they may linger longer in the breeding or stopover areas, leaving only when food supplies dwindle or are shut off by snow and ice. Mean autumn migration dates may therefore vary greatly from year to year, depending on local food supplies, as may rates of travel. This situation is exemplified by most short-distance migrants, especially irruptive seed-eaters, and by waterfowl and others affected by frost. For example, the peak date for passage of Eurasian Siskins through Falsterbo Bird Observatory in south Sweden during 1949–1988 varied from 15 August (in 1988) to 17 November (in 1958), the last date the station was manned that year (Roos 1991). At another site, Eurasian Siskins passed in

Steppe Buzzards (*Buteo buteo vulpinus*).

Klaus Bjerre.

largest numbers, and at the earliest dates, in years when birch seeds (the main autumn food) were scarce (Svårdson 1957). Likewise, the date on which the last Whooper Swans (*Cygnus cygnus*) left Lake Chuna on the Kola Peninsula each year during 1931–1999 varied between about 20 September and 9 November, depending on when the lake froze over (Gilyazov & Sparks 2002). These observations illustrate the point that some migrants depart only when deteriorating conditions encourage them to leave. Together with variable conditions on migration routes, this facultative response gives wide variation in the dates that particular species arrive in their various wintering areas, the more distant of which may be reached only in occasional years.

Split migrations

Although autumn migration is usually considered as a single event, consisting of alternating periods of flight and fattening, some species break their autumn journeys for periods of several weeks, much longer than is needed for refuelling. Some even moult during this break in migration. This behaviour is shown by many Eurasian migrants to Africa, such as the Marsh Warbler (*Acrocephalus palustris*) and Garden Warbler, which remain in the northern tropics for several weeks, and only later move on to the southern tropics (Jones 1995). In this way, they get the best from both regions, remaining in the northern tropics until conditions deteriorate, and arriving in the southern tropics at the optimal time, after fresh rains have promoted vegetation growth. Interrupted migrations are also evident in various irruptive and other facultative migrants that break their journeys to exploit food supplies they encounter en route, and travel much further from their breeding areas in some years than in others (Newton 2006, 2008, Svårdson 1957). One consequence of split migration is that the outward journey (including the break) takes more than four months in some species, whereas the return journey in spring can take only 1–2 months.

Spring migration

Birds normally leave their wintering areas so as to reach their nesting areas in time to breed at the most favourable season. Many migrants winter so far from their breeding areas that they could not judge conditions there from their position in wintering areas. They can only leave their wintering areas at a time that natural selection has decreed is appropriate, using an internal timer combined with local conditions as a cue. Among species wintering in the temperate zone, the main known environmental stimulus for spring migration (perhaps superimposed on an endogenous rhythm) is increasing daylength which promotes extra feeding, fattening and migratory restlessness at appropriate dates for the population concerned (King 1972, Lofts *et al.* 1963, Rowan 1925). In species that undergo a spring moult, this is also initiated by increasing daylengths, as is gonad growth, each of these processes occurring in appropriate overlapping sequence through the season. The role of daylength has been shown repeatedly in experiments on captive birds, in which longer-than-natural photoperiods advance all spring-occurring processes, whether gonad growth, pre-nuptial moult or migration.

As in autumn, however, the effects of daylength may be modified by both temperatures and food supplies. Every bird watcher outside the tropics can see that summer migrants arrive later in cold springs than warm ones, and that migrants can be held up for many days during a cold snap. This situation has been duplicated experimentally. For example, captive White-crowned Sparrows (*Zonotrichia leucophrys*) exposed to air temperatures increasing from 5°C to 26°C advanced the time of migratory restlessness compared with control birds (Eyster 1954, Lewis & Farnier 1973). However, it is hard to tell whether temperature acts directly on the birds, or through its effect on their energy needs and the food available for fuelling.

Different populations of a species wintering in the same area

Different species wintering in the same area, and hence subject to the same daylength regime, may start their migrations at different dates, weeks or sometimes months apart, depending on the distance they have to travel and the dates their breeding areas become fit for occupation (for shorebirds see Piersma *et al.* 1990). Such differences are also found in different races (or populations) of the same species wintering in the same area, as shown for White-crowned Sparrows in California (Blanchard 1941) and for Yellow Wagtails (*Motacilla flava*) in tropical Africa (Curry-Lindahl 1958, 1963). Although exposed to the same winter conditions, the members of the various races

differ in the dates at which their gonads develop, and at which they accumulate fat and depart for breeding areas (Blanchard 1941, Curry-Lindahl 1963, Fry *et al.* 1972). In general, in these northern hemisphere species, races that breed furthest south are first to leave their wintering areas, and those that breed furthest north are last to leave. Thus, in the Yellow Wagtail, the first to leave in spring is the southern race *M. f. feldegg*, then *M. f. lutea*, followed by *M. f. flava* and *M. f. flavissima*, and finally *M. f. thunbergi*. These various races arrive in their breeding areas in the same sequence, spanning the period March–June, from south to north. Inherent differences in endogenous rhythms could explain such population differences, as could inherent differences in the threshold daylengths required to trigger departure. Either mechanism could account for how birds of different races can leave their shared wintering area in appropriate sequence and reach their respective breeding areas (at different latitudes) at appropriate dates. However, the Yellow Wagtails are the more remarkable because several races winter together on the equator, where daylength is constant year round. In these birds, endogenous control seems essential, with different races responding differently, according to where they breed, and setting their ‘internal clocks’ before they reach the equator, so as to leave at appropriate dates some weeks or months later.

Return migration from variable wintering areas

In many bird species, the migrants from particular breeding areas can winter over a wide span of latitude and daylength regimes. For example, Eurasian Siskins breeding in the northern boreal forest of western Europe may winter anywhere between mid Sweden and Morocco, a latitudinal span of about 30 degrees, and the same individuals may winter at widely separated places in different years (Newton 2006). The general pattern in such species is that return migration begins earliest from the most distant (most southern) parts of the wintering range, and latest from the most northern parts. This sequential withdrawal from lower to higher latitudes can be spread over many weeks. It has been examined in detail in White-crowned Sparrows wintering in western North America. In these birds, the date of onset of pre-migratory fattening varied linearly with latitude (and hence with solstitial daylength), averaging 3.3 days later for each degree of latitude northward. The start of withdrawal was thus spread over seven weeks from the 14 degrees of latitude involved (King & Mewaldt 1981). Mean rates of fattening were the same in all areas, regardless of latitude.

Deferred return to breeding areas

In some long-lived bird species with deferred maturity, individual migrants leave their natal areas towards the end of their first summer, and do not return in the next spring, but only in a later one, when they are two or more years old. Other individuals may return part way towards breeding areas, or may visit breeding areas only for a short time each year, leaving wintering areas later and returning earlier than breeding adults. They perform both migrations in less hurry than the breeding adults, and in more favourable conditions. Such patterns are shown by various raptors, seabirds, shorebirds and others in which individuals do not breed until they are several years old.

Most of the first-year shorebirds that stay in ‘wintering areas’ show no sign of pre-migratory fat deposition or spring moult into breeding plumage, but remain light in weight and in well-worn winter plumage until the next ‘post-breeding’ moult in late summer into new winter plumage. In other individuals, ‘pre-breeding’ moult and fattening are much delayed, sometimes into July, too late for the birds to breed that year (McNeil *et al.* 1994). Lack of both weight gain and pre-breeding moult was apparent among juvenile Curlew Sandpipers in South Africa, among Ruddy Turnstones (*Arenaria interpres*) in Scotland, and among Western Sandpipers (*Calidris mauri*) in Panama, while adults wintering in the same places began moult, accumulated body fat and left in spring in the usual manner (Elliott *et al.* 1976, Metcalfe & Furness 1984, O’Hara *et al.* 2002).

Although the birds that stay year-round in wintering areas do not always undergo the pre-breeding moult into summer plumage, their late summer post-breeding moult can occur up to several weeks earlier than in adults returning from breeding areas. Ruddy Turnstones over-summering in England moulted seven weeks earlier than adults returning from their arctic nesting grounds (Branson *et al.* 1979), and Western Sandpipers over-summering in Panama moulted 3–4 weeks earlier than returning adults (O’Hara *et al.* 2002). They provide an example of birds moulting at a more genial time of year when not constrained by breeding to a less favourable time later in the year. More study is needed before we can hope to understand the mechanisms

that control the occurrence and timing of migration in such species during their early years of life.

Recent changes in migration patterns

Mainly in association with climate warming, many birds have changed their migratory behaviour in recent decades, arriving earlier in spring on their breeding areas, and often also departing later in summer or autumn (Newton 2008). In some once wholly-migratory species, some individuals are now remaining in breeding areas year-round, while other individuals are migrating less far than before. In general, such changes are most obvious in regions with the greatest climate change, and are more marked in short-distance than in long-distance migrants. Other species have extended their breeding areas into higher latitudes, where they have become more migratory. Not all these changes are necessarily linked with climate warming, however, as some major changes in food-supplies were human induced. An example is the increased feeding of garden birds in winter, which has enabled some formerly migratory species to remain at higher latitudes in winter, almost entirely dependent on these handouts. The important point is that migratory behaviour has proved flexible, changing rapidly in response to altered conditions. Some of these behavioural changes may have a genetic basis, resulting from the action of natural selection, whereas others may represent facultative responses to environmental changes. Whatever the basis, it is this facility for rapid modification of migratory behaviour which presumably enabled birds to respond to the great glacial changes of the past, and will enable them to adapt to future changes.

Migratory fuelling

At times of migration, as mentioned above, many birds put on extra body fat and other reserves for use as fuel during the journey. Typically, they divide their migration into periods of flight, during which reserves are depleted, and stopovers, when reserves can be replenished by feeding. Species that travel over favourable terrain tend to migrate in short flights, each lasting up to several hours, broken by periods of rest and foraging, when they can replace the relatively small amounts of fuel used on each flight. Given suitable weather, migratory flight can, in theory, occur for part of every day until the journey is completed. However, birds that migrate over seas and other large inhospitable areas have to sustain much longer fasts during flights of up to several days. These flights are preceded by days or weeks of feeding when much larger body reserves are accumulated. Passerines and shorebirds typically take 1–3 weeks to accumulate the fuel reserves necessary for such long journeys, and before departure some may have doubled their normal weights.

Energy needs and body composition

Per unit of weight, fat provides much more energy than any other storable biochemical fuel available. The use of 1 g of fat will yield around 9.2 kilocalories (or 38 kilojoules) of energy, compared with only about 1.3 kcal (5.3 kJ) from 1 g of protein or 1.0 kcal (4.0 kJ) from 1 g of carbohydrate (Table 1). Weight for weight, therefore, fat contains 7–9 times more energy than alternative fuels, providing the maximum energy storage for the minimum weight gain. Fat is an even more efficient fuel than high-octane vehicle fuel, and has the additional advantage that its oxidation yields an equal weight of water, thus contributing to another of the bird's needs during long-distance flight. Moreover, unlike any other potential bio-fuel, fat can be stored without water or protein, and can also be digested efficiently with less loss of heat and no effect on body glucose. The main recognised drawback of fat is that its metabolism requires the breakdown of small amounts of protein to provide enzymes for the chemical processes involved (the citric acid cycle).

Fat is laid down as adipose tissue in various parts of the bird's body, especially under the skin, and in well-defined deposits within the wishbone (tracheal pit) and around the gut. Just before departure, the subcutaneous fat layer in some long-distance passerine migrants covers most of the body, only the central part of the breast muscle remaining uncovered.

Pre-migratory weight increase involves not only the deposition of fat, but also of body protein. Fuel should therefore be regarded as a combination of the two, but not necessarily in consistent proportions. In the most extreme species, protein contents increase prior to migration by less than two-fold, whereas fat contents may increase

Table 1
Energy and water yield of the three main fuel types in birds.
Modified from Jenni & Jenni-Eiermann (1998).

	Lipids in adipose tissue	Protein in skeletal muscle or digestive organs	Glycogen
Energy density (kJ g ⁻¹) in dry mass	39.6	17.8	17.5
Energy density (kJ g ⁻¹) in wet mass	37.6	5.3	3.5–4.4
Water content (%)	5	70	75–80
Metabolic water production (g water g ⁻¹ dry matter)	1.05	0.39	0.56
Total water production (g water g ⁻¹ wet tissue)	1.10	0.82	0.89–0.91
Water produced (g water kJ ⁻¹ expended from wet mass)	0.03	0.16	0.21–0.25

Note. One kilojoule (kJ) is equivalent to 0.239 kilocalories, and a kilocalorie is popularly called a 'calorie' in human dieting.

by more than 10-fold. Nevertheless, the protein and fat levels usually increase in step with one another during migratory fuelling, so appear to be closely correlated. Some species, such as Sandhill Crane (*Grus canadensis*), add protein and fat at migration times in the approximate ratio of 1:10 (Krapu *et al.* 1985), whereas other migratory birds lay down roughly equal weights of protein and fat in the ratio of 1:1 (see later). This difference may result simply from differences in the diets of different species, or in their metabolism, but it may also represent an adaptation to the different types of journey they undertake or their needs after arrival.

Some species alter the ratio of stored protein to fat between seasons. For example, the 40–50 g mass gain by 200 g Eurasian Golden Plovers (*Pluvialis apricaria*) during autumn stopovers consists almost entirely of fat, but a similar mass gain in spring consists chiefly of protein tissue (mainly muscle). This difference may be because Eurasian Golden Plovers face energy deficits on autumn migration and in winter when they eat mainly protein-rich earthworms, but in spring they risk protein deficits, when after arrival in arctic breeding areas they eat mainly berries but must soon produce eggs (Piersma & Jukema 2002). Another indication that birds can adjust their body reserves to oncoming needs derives from King Penguins (*Aptenodytes patagonicus*), which double their body mass before long fasts on land, but with reserves consisting of about 14% protein before incubation, and 29% protein before feather moult (Cherel 1995).

Compared to fat and protein, carbohydrate is of relatively minor importance as an energy source for migratory birds. It is present in the form of glycogen in the liver and muscle tissue. The highest glycogen values reported from birds amount to no more than about 3.0% of liver mass and about 0.5% of total body mass (Blem 1990).

The bodies of resident bird species, or of migrants outside the migration seasons, typically contain fuel amounting to 3–5% of their lean body mass. Some migrants apparently travel with reserves no greater than this. However, most regular passerine migrants depart with fuel loads amounting to 10–30% of their usual body mass, and those making especially long flights accumulate fuel loads between 40 and 70% of their usual mass, approaching 100% in a few species (Blem 1990, Fry *et al.* 1970, Lindström 1991, Moreau & Dolp 1970). Similarly, some shorebirds attain very large fuel loads, as high as 50–90% of lean body mass, but with a maximum of around 100% in those embarking on the longest non-stop flights. They may then lose up to half their body mass during their flights over the next few days.

In addition to fuel deposition, preparation for migration in many birds involves enlargement of the breast muscles, heart and blood vessels, and shrinkage of other organs less important in migratory flight (see below). It also involves the activation of enzyme systems for the storage and rapid mobilisation of fat, an increase in the erythrocyte (haematocrit) content of the blood to enhance oxygen transport during long flights (Jenni-Eiermann & Jenni 1991), and the modification of various aspects of behaviour, including the diurnal rhythm of activity to permit nocturnal flights in some otherwise diurnal species. All these changes vary between species, according to the types of journeys they undertake.

Mechanisms of fuel deposition

To deposit body fuel, a bird must increase its rate of food intake. This may be achieved in various ways, such as feeding more rapidly or for longer than usual each day, or by selecting from potential foods the most calorific and easily digestible items. This is shown by some warblers and other insectivores, which switch to mainly fruit at migration times, the sugars therein being easily converted to fats. A bird might also increase the size of its digestive tract, so as to increase the throughput and processing of food, as again shown in many species of passerines. Some waterfowl and shorebirds can feed both by day and by night, and can thus achieve higher rates of food intake than other birds, and correspondingly higher rates of fuel deposition. But the most obvious way in which a diurnal bird can conserve feeding time is to migrate at night. While this may not increase feeding time over what is usually available, it at least prevents potential feeding time being reduced by flight time.

Not only are birds able rapidly to store and metabolise large amounts of fat, they also undergo many other physiological changes, affecting skeletal muscles and various internal organs (Battley *et al.* 2000, Piersma 1998). Before departure on long journeys, exercise organs (pectoral muscle and heart) tend to enlarge and nutritional organs (stomach, intestine and liver) tend to shrink. This makes sense on long flights where weight reduction is at a premium. Prior reductions in nutritional organs appear most pronounced in populations about to over-fly oceans that offer few or no opportunities for emergency landings, let alone feeding. In other species, the digestive tract is apparently reduced during the flight itself, rather than beforehand, contributing to the

fuel and water needs of the migrant on its journey. Digestive organs are rebuilt after arrival at a staging or wintering site. Hence, a bird refuelling for long-distance migration is not like a plane landing, refuelling and taking off again. Unlike the plane, the bodies of long-distance migrant birds have to be partly reconstructed at each stopover and modified again before take-off (Piersma 1998). This is much less true of species that migrate by short flights.

In some waterfowl, notably geese, reserves accumulated before arrival in breeding areas, and especially at the last stopover site, help in egg formation and survival through incubation (Drent *et al.* 2003, Ebbinge & Spaans 1995, Newton 1977). Such geese often arrive before vegetation growth has begun in their breeding areas, when little food is available. They are described as 'capital breeders', because they reproduce largely on the strength of existing body reserves, and contrast with 'income breeders' which breed on the strength of food eaten at the time. In different goose populations, weight gains of 25–53% have been recorded before the birds set off on spring migration (McLandress & Raveling 1981). This is a lot for birds of this size. Females accumulate more weight than males, in association with the needs of egg production and incubation (in which males do not participate, except in nest guarding).

At least some species of high arctic geese, such as the Lesser Snow Goose (*Anser c. caerulescens*), Ross's Goose (*A. rossii*) and Brent Goose (*Branta bernicla*), can start egg-laying 2–5 days after arriving in breeding areas, before plant growth has begun. They seem to rely entirely on body reserves. Others feed and regain some weight after arrival, but still depend partly on body reserves accumulated further south (Bromley & Jarvis 1993). In Lesser Snow Geese, the relationship between body reserves and reproductive output was studied in females shot at various stages of breeding in the Northwest Territories of Canada (Ankney & MacInnes 1978). The potential clutch size of pre-laying females was found from the number of large vascularised follicles in the ovary, and it emerged that females with larger body reserves had, on average, larger potential clutches. In other females collected after laying, body reserves had been partly used, but the mean weights of remaining reserves from females that laid clutches of different sizes were not then significantly different. Apparently, clutch size in Lesser Snow Geese was determined by the size of nutrient reserves: females with the largest body reserves produced the most eggs. Breeding females used most of their remaining fat and protein reserves during incubation (85% and 24% respectively). Late in incubation when females had depleted their body reserves, some left their nests to feed, while others were found dead on their nests from starvation. Hence, to reproduce successfully in this area, female Lesser Snow Geese had to accumulate beforehand enough reserves to support the last stage of migration, egg production and maintenance during the four weeks of incubation. Only after hatch were females able to feed intensively again, and build up body condition for the return migration to wintering areas.

Navigation

One of the most amazing aspects of migration is how birds find their way over long distances, often through unknown terrain. Many species are capable of migrating year after year between exactly the same breeding and wintering places, located up to thousands of kilometres apart. Some pelagic seabirds wander widely over the oceans, yet each year return unerringly to their own particular nesting islands. Great Shearwaters (*Puffinus gravis*), for example, nest on the isolated Tristan da Cunha Islands, lying at 40°S in the South Atlantic and more than 2000 km from Africa, the nearest continent. In the non-breeding season these birds migrate northward in their millions, ranging over large parts of the North Atlantic. But they return each year with pinpoint accuracy to their tiny breeding islands, which are spread over only 45 km of ocean. Individuals occupy the same nest burrows from year to year, often lying within a metre of those of other individuals. These and other seabirds that migrate long over-water distances to small oceanic islands must surely be among the greatest of animal navigators. But how do birds achieve these remarkable feats of orientation and navigation over such huge distances?

It is not just a question of finding the way. Birds must know where in their journeys they need to do particular things, such as change direction or accumulate extra body reserves in preparation for a long non-stop flight. The fact that they can respond appropriately at specific places on their route again implies that they possess some geographical sense — an ability to detect and respond in an appropriate manner to conditions at particular locations.

The most obvious way in which birds and other animals could find their way around on a day-to-day basis is by use of landmarks. But such features are useful only in familiar areas. When moving over longer distances into unknown terrain, a reliable

geographical reference system is needed by which to navigate. At least two types of factors can provide this reference—celestial and geomagnetic—and both are used by birds as directional aids (for reviews see Able 1980, Åkesson 2003, Emlen 1975, Wiltschko, R. & Wiltschko 1995, Wiltschko, W. & Wiltschko 2003). In migratory birds, compasses based on the sun, various sunset cues, stars, and magnetic information have been studied in detail, but a prior requirement for using any compass is that the bird should ‘know’ beforehand—either by inherent preference or experience—in what direction it needs to head.

Moreover, one feature of celestial cues, such as the sun and stars, is that they appear to change in position through each 24-hour cycle, as the earth spins on its axis. In the northern hemisphere, the sun lies in the south and moves during the day from east to west, and at night the stars rotate anticlockwise around the geographical north. In the southern hemisphere the sun lies in the north and moves from east to west, while the stars rotate clockwise around the geographical south. In using the sun and related factors in direction finding, therefore, birds in both hemispheres must allow for time of day. The same is not necessarily true for star patterns if they are used solely to indicate geographical north or south, determined by the centre of rotation of the night sky. Time-keeping depends on the internal clock, kept to time by the regular day–night cycle of light and dark.

The sun compass

The height of the sun’s arc in the sky varies with latitude and season, but it is always symmetrical with respect to true north or south. Its highest point in the sky at mid-day indicates due south in the northern hemisphere and due north in the southern hemisphere. The use of the sun as a compass by birds has been known for more than 50 years. Under a sunny sky, Common Starlings kept in circular wire cages during the migration period oriented in the same direction as free-living birds. They varied the angle they took to the sun according to the time of day. If the sky became overcast, their directional preference disappeared. When their view of the sun’s direction was changed using mirrors, the birds oriented at the same angle to the apparent sun as they would to the real sun (Kramer 1952, 1957). These experiments confirmed that starlings made use of a sun compass, which gave accurate information only if used in association with an internal clock, allowing adjustment of directional preference as the sun moved across the sky. Additional experiments in which Common Starlings were kept under artificial cycles of day and night of the same duration as natural time, but out of phase, revealed clearly that, in order to orientate, the birds used both the sun’s position on the azimuth (direction from the observer) and the time of day. Given a simulated stationary sun, a caged migrant orientated at different angles to it according to the time of day. The use of a sun-azimuth compass has now been confirmed experimentally in several species, and may be commonly used by diurnal migrants.

If homing pigeons and other species known to use the sun in orientation are transported to the southern hemisphere, they orientate themselves incorrectly, interpreting the sun as if they were in the northern hemisphere, indicating south rather than north. Regular trans-equatorial migrants must presumably be able to make the necessary adjustment, but how they do so is still unknown.

Skylight polarisation patterns

The ability of birds to detect sky polarisation patterns, which change with respect to the sun’s position (being particularly striking around the time of sunset), has also been demonstrated by experiment (Able 1993). Several species of normally nocturnal migrants have been shown to respond to manipulations of polarised skylight, especially around the time of sunset. The birds were tested individually outdoors in otherwise normal conditions in cages covered by sheet polaroids (Able 1982, 1989, Helbig & Wiltschko 1989, Moore & Phillips 1988, Phillips & Moore 1992). In each case, the birds changed orientation as predicted by alterations in the alignment of the polaroids. The experimental birds were clearly responding to polarised light as such, rather than to other sunset features.

The star compass

Providing that enough of the night sky is visible, nocturnal migrants proved able to use the stars as a guide. When tested in orientation cages, they could orientate cor-

Common Starlings (*Sturnus vulgaris*).
Denmark.
Hanne & Jens Eriksen.

rectly on clear starry nights, but became inactive or disoriented under overcast skies. They also became confused if star patterns were varied experimentally in a planetarium (Emlen 1967a, 1967b, Sauer 1957). When Indigo Buntings were tested under a natural starry sky during autumn migration, they preferred southerly directions. They maintained this southerly preference under an artificial star pattern imitating the natural sky in a planetarium. But when the artificial star pattern was changed by 180° , the birds changed their directional preference to the north. Under a static night sky, no obvious migratory restlessness occurred. The development of a star compass evidently involved learning, with celestial rotation as a directional reference, and captive Indigo Buntings without early experience of the night sky failed to orientate correctly in a planetarium (Emlen 1967b, 1975). Similar results were later obtained with Garden Warblers (Wiltschko *et al.* 1987).

In experimental conditions, some birds learnt to respond to a simplified and reduced star pattern, with some constellations blocked out, so long as this pattern rotated about a single conspicuous star. Nestling Indigo Buntings raised under an artificial sky with the star Betelgeuse (in the constellation Orion) as the point of rotation treated Betelgeuse as the Pole Star when subsequently tested. Detecting the rotation of the night sky probably takes considerable time—it could not be determined at a glance. Not surprisingly, therefore, the birds did not depend on the axis of rotation *per se*, but rather learned star patterns that indicated the axis, and thereafter they relied on those patterns. As with the sun compass, however, the ability and tendency to acquire this knowledge was apparently innate.

The use of a star compass has now been demonstrated experimentally in at least six different bird species, and may be general in nocturnal migrants. If the birds use the rotating star pattern only to define the position of the poles, then no correction for time of day is necessary. They may, however, gain further information from star patterns: as long-distance migrants proceed on their journeys over several weeks, stars that were once visible disappear below the horizon behind them, while others appear above the horizon in front, another indication that birds are unlikely to rely throughout on particular star patterns.

Celestial cues and time shifts

In using celestial cues, long east–west migrations present greater navigational problems than north–south flights because they involve time shifts, as the birds pass through successive time zones. If long-distance migrants using celestial cues to navigate did not allow for time shifts when travelling east–west (or west–east), they would make ever greater directional errors, and veer progressively further off course. The problem created by time shift is greatest at the highest latitudes, where the longitude lines are closest together, requiring more rapid adjustment. Hence, a second presumed function of an internal clock is to measure the changes in timing of sunrise and sunset, as the bird flies long distances west or east. High-latitude east–west or west–east flights are fairly common, being performed every year, for example, by the many waterfowl and seabirds that migrate along the northern coasts of Eurasia and North America to reach the Atlantic or Pacific Oceans on either side.

The magnetic compass

The second major system of bird orientation makes use of the earth's magnetic field, which has both horizontal and vertical components. Imagine the earth as a hugely powerful magnet, whose north magnetic pole is situated fairly close to the geographic North Pole, and whose south magnetic pole is similarly close to the geographic South Pole. Running through the atmosphere between the two magnetic poles are invisible longitudinal lines of magnetic force, which circle the globe rather like the segments of an orange. At the equator, the magnetic force lines run horizontal to the earth's surface, but toward higher latitudes they dip more and more strongly into the earth, becoming vertically downward at the magnetic poles. The inclination of the field lines thus varies within each hemisphere according to latitude. Hence, for any creature that can measure the inclination of the force lines, the earth's magnetic field can give a cue to latitude and direction (toward the equator or pole) within each hemisphere. However, it cannot give a reliable cue to longitude, so it cannot provide a firm basis for 'bi-coordinate navigation' (although this may be possible in some regions because of irregularities in the field). In contrast to celestial cues, however, the magnetic field can give consistent information in all weather conditions, both day and night, and unlike the sun compass, it needs no correction for time of day.

As revealed by radar studies, nocturnal migrants can occasionally orientate correctly even under completely overcast conditions, as can caged birds with no view of the sky. Caged birds lost this ability when isolated from both the sky and the earth's magnetic field behind metal-reinforced walls. Moreover, when the magnetic field experienced by caged European Robins was rotated using a powerful electromagnetic coil so that, for example, magnetic north was shifted to the east while the field's total intensity and inclination, as well as other potential directional cues, were kept unchanged, the birds altered their orientation accordingly (Wiltschko 1968). This crucial experiment showed conclusively that birds can respond appropriately to the earth's magnetic field. Since then, the use of a magnetic compass has been demonstrated experimentally in about 20 bird species, and its use may be widespread, but mainly in association with other information. Although the method of its perception is still unclear, birds are sensitive to both inclination and intensity, but apparently not to polarity (Wiltschko & Wiltschko 1972).

Use of multiple orientation cues

Experiments thus indicate that birds can use a number of different compasses for orientation during long-distance migration, based on information from the sun and related pattern of skylight polarisation, from star patterns and from the earth's magnetic field. Birds can learn and modify their use of all these compasses during their early lives or later. These different cues would normally give the same directional message. However, they might vary in reliability between regions, seasons and local conditions, so that for instance the sun compass cannot be used if the sky is totally overcast, the star compass might not be visible during the round-the-clock daylight in high-latitude summers, and a magnetic compass based on the angle of inclination is of little use around the geomagnetic poles and the geomagnetic equator (Åkesson *et al.* 2001). In practice, individual birds probably use information from more than one compass mechanism, with emphasis on whatever cues are most reliable in the conditions prevailing, switching from one type of cue to another during the course of a journey, depending on location, weather and light values (Muheim *et al.* 2006, Wiltschko, Weindler & Wiltschko 1998).

Which of several potential compasses is most important to a bird at a given time has been investigated in so-called 'cue-conflict' experiments. These involve presenting a bird with two (or more) orientation cues at once, manipulating one of them while leaving others unchanged, and monitoring the response of the bird (Able 1993). A typical experiment might involve placing an orientation cage surrounded by electric coils outdoors under a clear night sky. In this situation, the bird would have access to two known orientation cues, the stars and the magnetic field. The coils can be used to shift the direction of magnetic north so that magnetic compass directions differ from star-based ones. If, as compared to control birds tested in an unaltered magnetic field, the birds experiencing the cue-conflict changed direction in line with the magnetic field shift, one would conclude that in this situation magnetic information took precedence over stellar information.

Just such an experiment was conducted on three species of *Sylvia* warblers and European Robins captured on migration (Wiltschko & Wiltschko 1975a, 1975b). When the directions of stellar and magnetic north were at variance, the birds seemed to orient preferentially with respect to magnetic cues. The warblers changed direction during the first test in the conflict situation, but the robins did not shift until tested in cue-conflict for several consecutive nights (a finding later replicated on the same species elsewhere, Bingman 1987). Robins apparently needed longer to work out the changed relationship between stellar and magnetic cues.

Cue-conflict experiments have proved especially useful in assessing the cues used around sunset, a time when many birds set off on migratory flights. Orientation based on visual cues between the time of sunset and the appearance of the first stars could be based on the sun itself (e.g. the azimuth of sunset) or on patterns of polarised skylight as mentioned above. Both could provide the same reliable directional information. However, in cue-conflict experiments involving several different species, polarised light appeared to be the predominant influence on directional preference when placed in conflict with the sun's position or magnetic directions (Able 1993).

So far, we have considered only compass directions, but experienced birds can practice bi-coordinate navigation to re-find places they have previously visited. Such navigation could be provided by any two non-parallel gradients, and in theory the different gradients could be provided by different types of cues, for example one coordinate being based on a celestial cue and another on a magnetic cue. Whereas latitude can be fixed by both celestial and magnetic cues, longitude seems much more difficult

Black Storks (*Ciconia nigra*) and Steppe Buzzards (*Buteo buteo vulpinus*).
Eilat, Israel.
Klaus Bjerre.

to determine. Displacement experiments with White-crowned Sparrows in arctic North America indicated that a combination of geomagnetic and celestial information might be used to define longitude, but the precise mechanism remains unclear (Åkesson *et al.* 2005).

Another way in which different types of cues are not necessarily independent of one another is that a bird may calibrate one compass cue against another. Thus, while the rotation of the earth relative to the sky provides a stable reference for defining geographic north and south, changing geomagnetic declination (waviness in the force lines) renders the earth's magnetic field less reliable in this respect. Accordingly, young birds were found able to use celestial information to calibrate a migratory orientation response to the earth's magnetic field (Weindler *et al.* 1996). The combined experience of the night sky and the natural geomagnetic field seemed crucial for songbirds at high latitudes to find the appropriate migration direction to a population-specific wintering area (Weindler *et al.* 1996). Experienced adult Savannah Sparrows (*Passerculus sandwichensis*) also used celestial cues to recalibrate their migratory orientation to an experimentally shifted magnetic field (Able & Able 1995). Subsequent experiments revealed that Savannah Sparrows used polarised light cues from the region of sky near the horizon to calibrate the magnetic compass at both sunrise and sunset (Muheim *et al.* 2006).

In another study, *Catharus* thrushes caught on migration were exposed to an experimentally deflected magnetic field during twilight, and then released and radio-tracked on their subsequent night flights (Cochran *et al.* 2004). Their tracks indicated that the thrushes recalibrated their magnetic compass in relation to twilight cues, and then relied on their (miscalibrated) magnetic compass for their nocturnal flight, apparently ignoring stellar cues. The experimental birds changed to normal orientation again on succeeding nights, apparently having recalibrated their magnetic compass (correctly) back to north. Daily recalibration of the magnetic compass could explain how birds cope with changes in magnetic declination during the route, as well as various local magnetic anomalies; it could also explain how birds operating with a magnetic inclination compass can cross the equator (where the force lines are horizontal) without becoming disoriented.

Response to specific areas

Experiments using an artificial magnetic field implied that some birds use magnetic information to indicate regions where they must stop migrating, change direction or accumulate large fat reserves before crossing a barrier. For example, young migratory European Pied Flycatchers from western Europe showed a distinct change in compass heading when exposed in captivity to values of the magnetic field normally encountered in southern Europe, where the normal migratory route shifts from southwest to south. However, the altered magnetic field was followed by the shift in orientation only when applied at the appropriate time during the migratory period (Beck & Wiltschko 1988). In European Pied Flycatchers, therefore, the magnetic conditions of the location where the change is to occur and the time programme evidently interact to produce an appropriate response in an appropriate region.

In another experiment, some juvenile Thrush Nightingales (*Luscinia luscinia*) were caught in autumn in Sweden and exposed there to the geomagnetic conditions they would normally experience in northern Egypt. These birds promptly accumulated high fat levels appropriate to the subsequent desert crossing. They contrasted with control birds, exposed to local geomagnetic conditions, which accumulated much smaller fat reserves typical for south Sweden (Kullberg *et al.* 2003). However, birds trapped late in the onset period of autumn migration accumulated a high fat load irrespective of magnetic treatment. It seemed that the relative importance of endogenous and environmental factors in individual birds was affected by time of season, as well as by geographical location.

These experiments suggest that inexperienced birds on their first migration can detect and make use of the geomagnetic field, at least to indicate when major changes are needed during their journeys. The implication is that such birds have an inborn response to external geographic cues (especially geomagnetic cues) that are characteristic of certain latitudes or regions, and that they can use particular conditions to trigger a change in direction or fattening regime (Beck & Wiltschko 1988, Fransson *et al.* 2001). At least two mechanisms seem to be involved. The first is an endogenous time programme which switches particular activities on and off at appropriate times in the migration cycle (see above). The second is a response to particular latitudes or more specific regions, at least partly through regional magnetic or other conditions, which can similarly trigger appropriate changes in migratory behaviour. How much

these separate mechanisms act independently or in conjunction with one another is an open question, but different species would not necessarily be expected to respond to particular experiments in the same way.

Birds that have experienced a wintering area may use the magnetic conditions there to halt migration on subsequent journeys. Adult Tasmanian Silvereyes (*Zosterops lateralis*) were tested near the mid-point of their south–north migration in southeast Australia. Birds exposed in captivity to artificially generated magnetic field values of inclination and intensity normally experienced near the start of their migration, oriented correctly toward north-northeast. In contrast, birds exposed to magnetic field values that they would experience near the end of their migration ceased to show any significant directional preference; in this respect, they acted as though they had arrived in wintering areas (Fischer *et al.* 2003). In contrast, no effects of changing the artificial magnetic field were noted in inexperienced young birds caught prior to their first migration, and which had therefore never visited the wintering area. The implication is that birds can learn the magnetic conditions of areas important to them, and use these conditions to indicate when to stop migrating.

Rhumblines and great circle routes

An unresolved question in migration research is whether long-distance migrants travel on straight ‘rhumblines’ routes (also called loxodromes) or on great circle routes (also called orthodromes). Navigationally, rhumblines are the most straightforward, because the bird could set off in the appropriate direction and maintain the same compass heading throughout its journey. If the route ran directly north–south, it would also be the shortest route between two points on the earth’s surface and would not involve a time-shift. However, if the journey had an easterly or westerly component, so that it involved crossing lines of longitude (as most routes do), a constant heading would still be the simplest but not the shortest route. The great circle route covers the shortest distance between two longitudinally separated points on the globe, but requires continual change in heading during the journey. Great circle routes are thus more demanding in their navigational needs. They can be accomplished by aeroplanes, with sophisticated navigation equipment, but whether by birds remains uncertain. Moreover, on any journey that involves longitudinal displacement, whether on rhumblines or great circle routes, the bird is also subject to time-shifts, as mentioned above. These time-shift problems are greatest at high latitudes where the longitude lines are closest together, but it is also at high latitudes where the distance savings on great circle routes are greatest.

The tracking of individual birds on their journeys has shown that many take a straight, constant-direction rhumblines route, even when they would save much time and distance by taking a great circle route. This held, for example, in Brent Geese migrating between the Wadden Sea and the Taimyr Peninsula in Siberia. However, it was not clear whether these geese took a rhumblines route because they were not capable of navigating the shorter (over-water) route, or in order to stay near the coast with its feeding areas. The shortest (great circle) route was about 4300 km, compared to the rhumblines of about 4700 km. Although the birds that were tracked kept closer to a rhumblines than a great circle, they also made continual minor deviations, bringing their average flight distance to 5000 km, at least 700 km (16%) further than the shortest possible route (Green *et al.* 2002). Similarly, Brent Geese travelling from Iceland to the Queen Elizabeth Islands in northeast Canada tended to migrate along fairly straight rhumblines routes to their breeding areas, and Red Knots (*Calidris canutus*) performed likewise (Gudmundsson *et al.* 1991). Again these routes took the birds mostly over land, where they could come to ground in inclement weather. Many other birds that have been studied have followed rhumblines routes.

In contrast, evidence that any birds take great circle routes (other than north–south) is as yet rather slender. Use of radar on the coast of northern Siberia revealed the occurrence of an east-northeast post-breeding migration, indicating direct flights between Siberia and North America, 1800–3000 km across the Arctic Ocean (Alerstam & Gudmundsson 1999). If the migrants gradually changed their orientation to the right during these flights, they would travel towards Alaska and neighbouring parts of Canada along the shortest possible great circle route to South America. The commonest species involved were the Pectoral Sandpiper (*Calidris melanotos*) and Red Phalarope (*Phalaropus fulicaria*), which winter on and near South American coastlines, respectively. This is one piece of evidence indicating that some long-distance migrants might travel along approximate great circle routes, but it will remain inconclusive until birds have been followed along more of the route. Ring recoveries from these or other candidate species are also insufficient to confirm travel by great circle

routes. Only when not influenced by topographic features, important feeding sites or weather patterns, would migrants be expected to follow either straightforward rhumbline or great circle routes, and this situation may be quite rare.

As a further point, among the known orientation mechanisms, only a sun compass with no compensation for changes in local time could lead birds along a track similar to a great circle route. If birds did compensate for the time shift, using the sun compass they would follow a route similar to a rhumbline route. Hence, either type of route would appear possible using the sun as a compass. However, routes based on use of the stars or the earth's magnetic field would invariably run closer to a rhumbline than a great circle route. One way in which birds could follow an approximate great circle route would be to divide the journey into stages with one or more appropriately positioned stopover sites, flying straight from one to another, but making a directional change at each one. Many landbirds are known to take roundabout routes in order to avoid long water crossings or high mountains, or to make use of re-fuelling sites that are off the most direct route. The journey is thus divided into successive legs with different main orientations. For example, most of the migrants that travel in autumn from western Europe to West Africa travel southwestward into southern Iberia, and then take a more southerly course into Africa. If they continued heading southwestward, they would end up far over the Atlantic Ocean.

Overall, straight rhumbline routes based on constant compass headings appear more likely in many bird populations, and are consistent with the routes frequently recorded by ringing and radio-tracking. They also fit the experimental evidence (based mainly on passerines) of a genetically fixed directional preference that steers inexperienced juveniles towards their wintering areas (although they may change directions at specific points on their journeys). Clearly, more research is needed on the precise routes taken by long-distance migrants before their navigation systems can be more thoroughly assessed.

Route-finding

In conclusion, the navigational tools available to migrating birds include: (a) a celestial compass based on sun, skylight polarisation and star patterns; (b) a magnetic compass based on the earth's magnetic field; (c) an internal clock, recording diurnal (circadian) and longer-term time changes; and (d) an inherited mean migratory direction and time programme, which together ensure that the bird flies in an appropriate direction for an appropriate time. Some, if not all, birds also have a map sense used for homing to a previously experienced place. Moreover, the fact that birds can re-find places they have already visited implies a good spatial memory.

Various other navigational methods may also be used by migrating birds, including the use of ultra-sound and odours. Tube-nosed seabirds, in particular, have a well developed olfaction sense which may be used for locating food and nest burrows, but may also be used in longer-distance navigation, although this idea is conjectural only.

Equipped with these navigation aids, a bird could use at least four different route-finding strategies:

1. In guiding or 'follow-the-leader', some birds might complete their migration by following others which know the way, thereby learning the route. Providing the leaders were experienced, they could pass on knowledge of travel routes to younger individuals by cultural transmission, assuming the youngsters could record and memorise their journey in some way. This strategy is used by swans, geese and cranes, in which young migrate with their parents. Any birds using this method would benefit from a back-up mechanism (such as clock-and-compass) in case they were left to migrate on their own. This method cannot be used by many other bird species, however, because the young migrate independently of the adults, and sometimes at a somewhat different time of year. One example is the Common Cuckoo (*Cuculus canorus*) in which the adults leave their breeding areas a month before their latest young, reared by various host species, have even left the nest.
2. In clock-and-compass (vector) navigation, birds aim to head in a constant migratory direction (which may change once or more times during a journey) for an innately determined amount of time controlled by an internal clock. By this mechanism birds could reach previously unknown but appropriate wintering areas. Theoretically, birds of all ages could use this orientation strategy, which has been demonstrated experimentally in young passerines and others. On this mechanism alone, birds are unable to determine their position and are therefore unable to correct for wind drift, directional mistakes, over-flight, or experimental displace-

Eurasian Cranes (*Grus grus*).
Finland.
Markus Varesvuo.

ment. Also, adults would be unlikely to return to the same precise localities in successive years, which many are known to do.

3. In bi-coordinate navigation, birds can sense at least two global coordinates forming a reliable grid through which they can determine their geographical position. Bi-coordinate navigation could provide continual positional feedback, enabling birds to correct for drift or directional mistakes. Theoretically, birds of all ages could use this strategy, but experimental evidence from several species suggests that it is used primarily by experienced birds returning to a known area.
4. In piloting, a migration route is retraced by using a sequence of learnt landmarks. This method would require birds to build a landmark-based map during a previous migratory journey which is retraced during each subsequent migration. Such landmarks could be visual, auditory, magnetic or olfactory. This method could not be used by inexperienced migrants on a first-time journey, but could help birds returning to a known area.

While we still have much to learn about this fascinating subject, migratory birds clearly have a number of orientation and navigation mechanisms available to them, and are not restricted to just one. They also have an inherent ability to learn to make use of the more important navigational cues, re-assessing them and if necessary cross-checking them at points along the route. By these various means, they can find their way each year between widely-separated localities, to the continuing amazement of mankind.

Birds as colonisers

Like other terrestrial organisms, land-birds that have the opportunity readily expand their geographical ranges across land areas, occupying all suitable habitats. A spectacular example is the Eurasian Collared-dove (*Streptopelia decaocto*) which in the mid-twentieth century colonised much of Europe from breeding areas further east. It is now a common village bird in areas where a century ago it was totally unknown. In addition, however, powers of sustained flight enable land-birds to cross extensive sea areas, and thereby to colonise distant lands in a way that most other animals cannot. As a result, land-birds of one sort or another are found on almost every oceanic island in the world, where other animal groups are poorly represented or altogether lacking.

Every bird-watcher delights in seeing occasional individuals of certain bird species, which normally live far away but periodically turn up as rarities. There can be no doubt that individual birds continually reach localities hundreds of kilometres beyond their normal range boundaries. Bird vagrancy is a familiar phenomenon, especially in well-watched places such as the British Isles, where more than half the species recorded in the last 200 years are classed as vagrants. Some appear in small numbers every year, but others only singly at intervals of many years.

In both Europe and elsewhere, vagrancy is especially evident on off-shore islands. Although the variety of species is somewhat restricted, and most vagrants are drawn from migratory populations, bird movement is clearly not the major obstacle to range extension. The main problem is the difficulty in establishment. Migrants blown off-course are usually programmed to re-fatten and move on, reducing the chance that they will stay in a new area. Unless they are adapted to the journey, birds that have crossed an ocean are likely to arrive so exhausted and low on body reserves that they have poor survival prospects, even in favourable environments; and even if individuals recover from the journey, remain and survive long enough to breed, their low numbers may render them vulnerable for several years.

Despite the difficulties, some remarkable trans-oceanic range extensions have occurred among birds in recent times. One remarkable example is the Cattle Egret (*Bubulcus ibis*) which around 1880 is thought to have crossed the Atlantic from Africa unaided, reaching Surinam in South America. From there it gradually spread to occupy grassland habitats through much of the New World, including Caribbean Islands. In the opposite direction, the same species spread from Asia via New Guinea to Western Australia, and then on to New Zealand. It has doubtlessly been helped by forest clearance, and the proliferation of cattle ranching, as it naturally associates with large grazing mammals to feed on the insects they disturb. Moreover, in the relatively short time since it arrived in these new areas, the Cattle Egret has established new migrations, including one between New Zealand and Australia.

Since the occupation of New Zealand by European people, and the resulting habitat transformation, several bird species have crossed the 1600 km of sea and colonised the country from Australia (Baker 1991, Bell 1991). Besides the Cattle Egret which

Greater Flamingos (*Phoenicopterus ruber roseus*).

Hanne & Jens Eriksen.

arrived around 1958, new colonists include: the Silvereye (*Zosterops l. lateralis*), since 1855; Grey Teal (*Anas gibberifrons gracilis*), re-established since 1916; Welcome Swallow (*Hirundo neoxena*), 1920s; Spur-winged Lapwing (*Vanellus spinosus*), since about 1932; Masked Lapwing (*Vanellus miles*), since 1940; White-faced Heron (*Egretta novaehollandiae*), since 1940; Royal Spoonbill (*Platalea regia*), since 1950, still rare; Common Coot (*Fulica atra*), since 1954; and Black-fronted Dotterel (*Elseyornis melanops*), since 1954. Such species may have reached New Zealand in earlier times, but did not persist, possibly because suitable habitat was lacking then. They contrast with many other animals which have reached New Zealand only with more direct human help.

Concluding remarks

From time immemorial, the seasonal movements of birds have fascinated people. They have continually raised questions about where particular species come from, where they go, how they time their journeys, and how they find their way. After more than a century of scientific research, we have come a considerable way towards answering these questions in broad terms, at least for northern hemisphere species. But substantial gaps in our understanding still remain, notably on important aspects of navigation, fuel accumulation and use on journeys, and the control of migratory timing. In addition, for obvious reasons, we still have only skimpy knowledge of the movement patterns of pelagic birds which spend most of their lives on the open sea. As time goes by, research is likely to extend to a wider range of species, and to other parts of the globe, while developments in technology will make more things possible. In the foreseeable future, smaller and more sophisticated radio-transmitters are likely to become available, enabling us to follow much smaller birds, such as swallows, day by day on their journeys, recording the heights at which they fly, the precise routes they take, and when and where they stop to rest and feed. No doubt future discoveries, like previous ones, will generate excitement and awe in scientists and lay people alike, as we continue to be amazed at what migrating birds can do.

Introduction to Volume 13

Readers are invited to consult the Introductions to previous volumes for explanations of the aims and norms of the HBW series. We do not wish to abuse the patience of regular readers by repeating these same details too often!

Volume 13 covers the creeper and nectarivore groups of traditional classifications, and makes a start on the shrike block. Australasia is again very well represented in this volume, in no small measure due to the large and diverse honeyeater family, Meliphagidae.

The foreword that graces the current volume is on another of the subjects most frequently requested by readers—migration. We have been particularly fortunate that Professor Ian Newton accepted authorship of this essay, covering surely one of the most fascinating subjects in ornithology, and indeed in the natural world. We are quite sure readers will agree that this fine contribution makes an excellent addition to the HBW foreword collection.

We are also delighted and extremely grateful that Lars Jonsson very kindly allowed us to use his splendid plate for the frontispiece.

Sadly for us, with this volume we have to say goodbye to Teresa Pardo, who has decided to follow her calling and become a teacher. Tere started with HBW in 1994, when she took over the Bibliography. As each volume has gone by, she has become more and more important until she has become effectively a fourth Editor. We wish her all the very best in her new job, and hope she will drop in often to keep tabs on us! In the meantime, we are very pleased to report that she has maintained her link with HBW by compiling the Index of the present volume, as well as running a check on the final publishing proofs—among other things.

We have been most fortunate in having ideal cover already available within the team. Both Frank Steinheimer and Amy Chernasky have considerably diversified their hugely important and time-consuming roles to fill the gap left by Tere. Both have been most worthy Assistant Editors on the current volume.

Issues of nomenclature have at times risen to the forefront, as in other volumes, and there are two particular cases that probably merit brief explanation. The family of the Wallcreeper (*Tichodroma muraria*) has for some years been given by various authors in two different versions, Tichodromidae and Tichodromadidae. Until the present volume HBW had adopted the latter spelling, as used, for example, by the Peters *Check-List*. However, closer examination of the case led us to the clear conclusion that, in accordance with Article 29 of the International Code of Zoological Nomenclature, the correct name is Tichodromidae (Art. 29.3.2), as indeed already indicated in Bock's (1994) monograph on the *History and Nomenclature of Avian Family-group Names*.

The other case in question required the formal establishing of priority between two genus names in the family Nectariniidae. In a recent paper in *Zootaxa* Frank Steinheimer has given *Leptocoma* Cabanis, 1851 priority over *Chalcostetha* Cabanis, 1851 (Nectariniidae) on the Principle of the First Reviser (see Steinheimer 2008b).

Acknowledgements

We are grateful for the kind assistance received from museums and their helpful staff, and we would like to give special thanks to the British Museum of Natural History at

Tring (Robert Prys-Jones, Mark Adams, Katrina Cook, Alison Harding), the American Museum of Natural History in New York (Paul Sweet, Peg Hart, Mary LeCroy), the Smithsonian Institution, National Museum of Natural History in Washington (James Dean), the Royal Museum for Central Africa in Tervuren (Michel Louette), the Peabody Museum at Yale University (Kristof Zyskowski), the Natuurhistorisch Museum at Leiden (Hein van Grouw), the Muséum National d'Histoire Naturelle in Paris (Eric Pasquet), the Australian Museum in Sydney (Walter Boles, Jaynia Tarnawski), the Field Museum in Chicago (David Willard, Mary Hennen), the Bernice P. Bishop Museum in Honolulu (Carla Kishinami) and the Zoological Museum at the University of Copenhagen (Jon Fjeldså, Geert Brovad).

In the editing of the bibliographies and also the scientific descriptions, we have been aided by a series of libraries and their on-line catalogues, notably the Museum für Naturkunde in Berlin, the British Museum of Natural History at Tring, Deutsche Ornithologen-Gesellschaft in Berlin, the American Museum of Natural History in New York, the Herzog August Bibliothek in Wolfenbüttel, the Preußische Staatsbibliothek in Berlin, and the Zoological Nomenclature Resource Page (www.zoonomen.net) maintained by Alan P. Peterson in Walla Walla, Washington.

We have been very fortunate to receive help from many individuals in a variety of ways, including refereeing texts, answering queries, providing access to unpublished information and literature, and proof-reading foreign-language references. We warmly thank Vasil Ananian, Óscar Arribas, Norbert Bahr, Rüdiger Becker, Ulf Beichle, Hans-Martin Berg, Walter Bock, Christiane Boehm, Jenny Bounds, Rauri Bowie, Carol Boyse, Axel Bräunlich, Katja Bräunlich, Stuart Butchart, Robert Cheke, Nigel Collar, Paul Cooper, Normand David, Edward Dickinson, Colleen T. Downs, Bob Dowsett, Françoise Dowsett-Lemaire, Guy Dutson, Jon Fjeldså, Christian Hogrefe, Michael P. S. Irwin, Hans Jakober, Martin Jones, Mikhail Kalyakin, Ragnar Kinzelbach, Guy Kirwan, Theo Kleefisch, Albrecht Manegold, Stuart Marsden, Tiffany Mason, Lionel Maumary, Gerald Mayr, Alan Peterson, Douglas Pratt, Christiane Quaiser, Hans-Ulrich Raake, Pam Rasmussen, Martina Rissberger, Gerard Rocamora, Peter Ryan, Svenja Sammler, Richard Schodde, Christian Sturmbauer, Lars Svensson, Jean-Claude Thibault, Kathleen M. C. Tjørve, Colin Trainor, Magnus Ullman, Laurent Vallotton and Mike Wilson. Particular thanks go to Svenja Sammler for her help in the editing of references, literature searches and the checking of original descriptions, and to Axel Bräunlich for his assistance with proof-reading. We are greatly indebted to Normand David for his generous assistance over several months in checking all the genus- and species-level taxa for gender agreement, correct spelling and other details. We also thank him and Edward Dickinson for being on hand for numerous consultations related to scientific names, their original descriptions and accurate dates. As ever, we would like to show our grateful appreciation to Guy Tudor and Michelle le Marchant for continuing to make available to us a wide array of photographs, which is invaluable for the plate preparation.

The French, German and Spanish names for the volume have been provided by Normand David, Peter H. Barthel, Einhard Bezzel, Renate van den Elzen, Frank D. Steinheimer and Eduardo de Juana, together with their respective associates. We thank them all for this important contribution.

On behalf of the individual authors and artists we extend our sincere thanks to Mark Adams, Craig Allen, Des Allen, Richard Allen, James Atherton, Elizabeth Baker, Neil Baker, Sabine Baumann, Bruce Beehler, Linda Birch, Mike Blair, Christiane Böhm, Walter Boles, Remi Borello, Wendy Borello, Jeffery Boswall, Rebecca Boulton, Raurie Bowie, N. Brickle, Murray Bruce, Donald Buden, Rosalind Burr, Pierre Cabard, John Cantelo, M. Catterall, Les Christidis, Michael Clarke, Darrell Clegg, David H. Close, Brian Coates, John Colebrooke-Robjent, Nigel J. Collar, Peter Cowan, Mike Crewe, the late Mike Cullen, Martin Dallimer, Geoffrey Davison, René Dekker, Ron Demey, Jared Diamond, Edward C. Dickinson, Paul F. Donald, Philippe Dubois, Guy Dutson, David Eades, John Eaton, Jen Elkin, Stephan Ernst, S. Ervin, Dave Farrow, Klaus-Dieter Feige, Chris Filardi, Clem Fisher, Jon Fjeldså, Robert Fleischer, Holly Freifeld, Tony Gaston, T. A. Gilissen, Brian Gill, Howard Ginn, Phil Gregory, Sue Gregory, Llew Grimes, Hein van Grouw, Nader Hamidi, Alison Harding, Simon Harrap, Margaret Hart, A. F. A. Hawkins, M. Prins, Serban Proches, Steve Pryor, Robert Prys-Jones, Brian Rabbitts, Richard Ranft, Frank E. Rheindt, C. Richardson, J. Riley, Craig Robson, C. S. (Kees) Roselaar, David Rounsevell, Douglas Russell, Volker Salewski, Margaret Sandwith, Miroslav Saniga, Fabian Schmidt, Joshua Seamon, Tony Sebastian, Patrick Sellar, S. K. Sen, D. A. Showler, Andrew Silcocks, Abdulrahman al-Sirhan, Adrian Skerrett, Hana Slabáková, Jill Smith, Claire Spottiswoode, Robert Stjernstedt, Paul Sweet, Simon Tamungang, Mike K. Tarburton, Jaynia Tarnawski, Cheryl Tipp, Uthai Treesucon, Klaus Uhlenhut, Eric VanderWerf, Michael Walters, Effie Warr, Ralf Wassmann, Edward L. Webb, David R. Wells, Bret Whitney, Gary Wiles, Mike Wilson, John Woinarski and Yong Ding Li, and also to the Alpenzoo in Innsbruck, the Australian Museum in Sydney, BirdLife South Africa, Birds Australia, the British Library Sound Archive, Coffs Harbour Public Library, Leipzig Zoo, the Museum Victoria in Melbourne, the National Museum in Bloemfontein, the Natuurhistorisch Museum at Leiden, Plymouth Library Services, the Queensland Museum in Brisbane, the Royal Society for the Protection of Birds, SASOL, and the Zoological Museum of Amsterdam.

As a special note, Reuven Yosef would like dedicate his contribution in this volume to the memory of his prematurely departed colleagues Tony Harris (South Africa) and Andreas Helbig (Germany).

For their continued support and assistance, we are grateful to M^a Josep de Andrés, Dolores Buxó, Juan Antonio Cantí, Cam Christie, Marc Duquet, Marta Fenollar, Fortunato Frías, Rosa Llinàs, Albert Martínez-Vilalta, Jordi Martínez-Vilalta, Isabel Martínez, Rafael Martínez, Anna Motis, Mary and Jim Ramsay, Olga Rius, Jamer Rivera, Iván Teba, Virginia Toledo and Aurea Vilalta.

As mentioned above, we are extremely grateful to Lars Jonsson for his most generously supplying the frontispiece to this volume. We also warmly thank Toni Llobet for another of his signature back-cover illustrations.

Finally, we should like to pay a special tribute to Dr Hans Löhrl, who died in June 2001. Dr Löhrl's huge contribution to the study of European birds is well known and much appreciated. When we originally approached him with a view to writing the family Tichodromidae, he was slightly reluctant to take on authorship, due to failing health. However, he did agree, but insisted on writing the text right away, years in advance of his deadline, to make sure that he was able to deliver. We are extremely grateful to him for this contribution, and to his widow, Frau Hildegard Löhrl, for assisting Mike Wilson in various aspects of the updating of the text.

Class AVES
Order PASSERIFORMES
Suborder OSCINES
Family REMIZIDAE (PENDULINE-TITS)

- Small to very small birds with sharply pointed conical bill, short to medium-length tail and relatively strong toes; plumage rather nondescript, but four species have bold head patterns and males of two others have colourful heads.
- 7.5–11 cm.

- Africa, Europe and Asia, and one species in southern North America.
- Open forest, waterside trees, reedbeds, desert with scattered vegetation, and montane forest.
- 5 genera, 13 species, 45 taxa.
- No species threatened; none extinct since 1600.

Systematics

Formerly treated as a subfamily, Remizinae, within the family of tits and chickadees (Paridae), the penduline-tits were recognized as being worthy of family status by C. Vaurie, in his 1959 review of Palearctic bird species. This decision was supported by K. H. Voous in 1977, in his taxonomic review of Holarctic birds. A decade or so thereafter, C. G. Sibley and J. E. Ahlquist produced a complete revision of the classification system of birds, following the results of their researches into avian phylogeny based on techniques of DNA–DNA hybridization. These authors revived the subfamily Remizinae, which they housed within an enlarged family Certhiidae. Nevertheless, the majority of authors have followed Vaurie and Voous in regarding the penduline-tits as representing a full family. One notable exception is in the 1996 monograph on the tits, nuthatches (Sittidae) and treecreepers (Certhiidae) by S. Harrap and D. Quinn, who continued to treat the penduline-tits and their allies as a subfamily of Paridae.

Of the five genera currently included within Remizidae, three are monotypic, and are quite different both from one another and from the rest of the family. The placement of these species in the present family remains controversial. In particular, these three species, namely the Verdin (*Auriparus flaviceps*), the Tit-hylia (*Pholidornis rushiae*) and the Fire-capped Tit (*Cephalopyrus flammiceps*), differ markedly from the two basic genera of penduline-tits, *Remiz* and *Anthoscopus*, although they do share certain anatomical features, notably the sharply pointed conical bill.

Sibley and Ahlquist, in 1990, moved the Verdin from their subfamily Remizinae and placed it with the gnatcatchers and gnatwrens (Poliophtilidae) in a subfamily, Poliophtilinae, of their very much expanded family Certhiidae. This move was not followed by F. H. Sheldon and F. B. Gill in their 1996 review of songbird phylogeny, which gave emphasis on the tits and their close relatives; these authors returned the species to the Remizidae, which is where it has remained. More recently, E. C. Dickinson, in the third edition of the *The Howard and Moore Complete Checklist of the Birds of the World*, published in 2003, retained the Verdin with the penduline-tits, as also did K. A. Jonsson and J. Fjeldså in their 2006 review and “supertree” of passerine birds. Nevertheless, it does seem extraordinary that such a small Old World group as the penduline-tits should have an aberrant relative living in the deserts of the southern USA

and Mexico; indeed, it may not be long before the Verdin is moved on again, but in the meanwhile it is housed with the penduline-tits.

The tiny Tit-hylia, alone in the genus *Pholidornis*, is the smallest African passerine, and it has had a remarkable taxonomic history. It was originally described, by J. Cassin in 1855, as a flowerpecker (Dicaeidae), but its similarity to these equally tiny, short-tailed canopy feeders of the Oriental and Australasian Regions is likely to be coincidental, having arisen through parallel

The placement and membership of the family Remizidae have had a fairly complex history. On occasion, the penduline-tits have been demoted to a subfamily, Remizinae, included within the treecreepers (Certhiidae) or tits and chickadees (Paridae). It is now generally considered a family in its own right, although the family limits still remain a matter of considerable debate. In addition to these matters, the number of species that should be recognized in the genus Remiz is the main subject of controversy. Some authorities consider there to be a single polymorphic species. However, structural, habitat and plumage differences suggest that there are actually four species, one being the Chinese Penduline-tit.

evolution, rather than being genetic. It has since been placed variously with the sunbirds (Nectariniidae), the waxbills (Estrildidae), the Old World warblers (Sylviidae), and the tits and chickadees, and alongside the unrelated Green Hylia (*Hylia prasina*) in a new family Hylidae, as well as with the Australasian honeyeaters (Meliphagidae). In 1975, C. J. Vernon and W. R. J. Dean proposed that the Tit-hylia was closest to the penduline-tits, and the two do, admittedly, share similarities in nest construction and roosting habits and in vocalizations, while aspects of their feeding behaviour and basic appearance bear reasonable comparison. On the other hand, *Pholidornis* has bright yellow legs and its upper mandible curves down to the tip, whereas all of the other members of the Remizidae have dark legs and a straight culmen. Until molecular-genetic research sheds light on its true affinities, however, it seems best to keep the Tit-hylia in the Remizidae.

Cephalopyrus, the third and final monotypic genus in the family, is a small bird of Himalayan oak (*Quercus*) forests. In its size and its general plumage coloration, the Fire-capped Tit is reminiscent of a *Phylloscopus* leaf-warbler. With its olive and yellowish plumage and the male's red crown and throat, it is perhaps not surprising that this species was formerly considered to be a firecrest or kinglet (Regulidae), but the final allocation of a family to this little Himalayan-forest oddity seems to be the Remizidae. This is not, however, entirely satisfactory, as *Cephalopyrus*, in contrast to the other species in the penduline-tit family, nests in tree holes, in which habit it resembles the true tits of the family Paridae; moreover, and in common with the Verdin, it lays blue, not white, eggs. Nevertheless, the Fire-capped Tit's song is very like those typical of the genus *Remiz*, as is its small cone-shaped bill, and it is considered best to retain the species in the Remizidae, pending further research. In this connection, it is of interest that the Fire-capped Tit employs a number of feeding actions and other movements which are typical of the penduline-tits, but do not appear in the true tits. In the 1960s, H. Löhr pointed out that *Cephalopyrus*, while feeding, will insert the closed bill into an object to prise it open; it also holds down a food item by grasping this with its foot, and it will reach forwards and, using its foot, pull leaves or food towards itself. All

of these mannerisms are shared with penduline-tits and are not exhibited by the parid tits.

The remaining two genera are the "true" penduline-tits, currently consisting of ten species. *Anthoscopus* contains six species, often termed "kapok tits", which B. P. Hall and R. E. Moreau considered to form a superspecies covering most of sub-Saharan Africa. The Forest Penduline-tit (*Anthoscopus flavifrons*), however, is markedly different from the other five, and C. H. Fry and colleagues, in volume VI of *The Birds of Africa*, considered this inhabitant of West and Central African lowland rainforest to be an independent species and best excluded from the superspecies. The most difficult member of this group to summarize clearly is the Grey Penduline-tit (*Anthoscopus caroli*), which has no fewer than eleven subspecies, these falling into five groups. Within this complex are what could well be two further species, represented by taxa which appear to overlap in range with other subspecies of *A. caroli* but without interbreeding, or which are separated from them by altitude or habitat type. In south Kenya and north Tanzania, the subspecies *sylviella* may be worthy of treatment as a separate species, for which the vernacular name of "Rungwe Penduline-tit" or "Buff-bellied Penduline-tit" has been proposed, with subspecies *sharpei* as a race. Indeed, this was the treatment accorded to these subspecies by Sibley and B. L. Monroe in 1990, but this has not been followed by more recent authorities. Farther south, in north-east Zimbabwe, the very poorly known subspecies *rankinei* may likewise merit elevation to species rank, and the name of "Zambezi Penduline-tit" has been suggested. Unfortunately, so little is known about this taxon that it is impossible to do other than highlight the possibility of its being a separate species, in the hope that researchers will turn to studying its relationships in the field. In this respect, the race *sharpei* is not very well known, either, and how close it really is to *sylviella* remains to be determined.

The final genus, *Remiz*, is no less controversial in the number of species that it contains. Most authors have opted for one polymorphic species, but as long ago as 1940 A. Ivanov pointed out that in the vicinity of the Syr Darya and the lower Waksh of western Tajikistan the breeding ranges of three forms met. He encountered White-crowned Penduline-tits (*Remiz coronatus*) in

All members of Remizidae are small or very small passerines. Even the largest birds, in the genus *Remiz*, do not exceed 11 cm in length.

Morphologically, the five genera have little in common other than a sharp, cone-shaped bill with a straightish culmen.

The Eurasian Penduline-tit has relatively sturdy legs, well suited to a life spent largely in the thick of reedbeds, whereas the more arboreal *Remiz* species have slighter tarsi.

Adults of this genus are relatively colourful and strikingly patterned birds, three species wearing a black facial mask, and the other a full black hood.

Females are duller than males.

Santofia, Spain.

Photo: Joseba del Villar]

deciduous forest of willow (*Salix*) and birch (*Betula*), whilst Black-headed (*Remiz macronyx*) and Eurasian Penduline-tits (*Remiz pendulinus*) only inhabited *Phragmites* reedbeds. In Tajikistan clearly these three penduline-tits were behaving as three species, with no evidence of interbreeding. Black-headed and Eurasian Penduline-tits do, however, hybridize in two areas of the lowlands flanking the Caspian Sea, namely the delta of the River Ural in the north and, in the south-west, the region between Lenkoran and the River Kura. The variable hybrid population at the mouth of the Ural has been given the name *bostanjogli*,

and those in the zone of variable hybrids in the south-west Caspian lowlands have been named as, respectively, *loudoni* and *altaicus*; the last-mentioned is sometimes recognized as a valid subspecies. On the other hand, the Black-headed Penduline-tit overlaps widely with the White-crowned Penduline-tit without interbreeding, a situation which has created a difference in habitat preferences, the former species favouring reedbeds while the White-crowned is more at home in open woodland or bushy hill-sides. Opinions on the speciation of *Remiz* held by Russian taxonomists and scientists tend to differ from those of most of their European counterparts, although one may suppose that the position of the Chinese Penduline-tit (*Remiz consobrinus*) has not yet been considered by the Russian taxonomists, for it has only very recently been found in the Russian Far East. Earlier, in 1955, L. A. Portenko treated *Remiz* as consisting of one variable species, whereas I. A. Dolgushin, 17 years later, accepted three species, namely the Eurasian, Black-headed and White-crowned Penduline-tits. In 1990, L. S. Stepanyan took a different view, by "lumping" the Eurasian and White-crowned Penduline-tits but treating the Black-headed Penduline-tit as a full species.

For so small a family as Remizidae, there are a surprising number of taxonomic riddles still to be solved. This, combined with the fact that all except one of the species construct an extremely elaborate oval nest of felted materials (see Breeding), helps to make the penduline-tits a most interesting and alluring family.

Morphological Aspects

The 13 members in this family of small arboreal birds range in size from the minute, stump-tailed Tit-hylia, which, with a total length of just 7.5 cm, is Africa's smallest passerine, to the moderately longer-tailed Eurasian penduline-tits, up to 11 cm in length. The tail of most of the species is shallowly notched, and the wings are relatively short and rounded, the outermost of the ten primaries being very short and narrow. Despite their short wings, the two northernmost species, the Eurasian and Chinese Penduline-tits, are long-distance diurnal migrants (see Movements).

Members of the Remizidae are a weakly united group of genera, the single unifying feature being a sharply pointed conical

The genus *Anthoscopus* contains six species, often called "kapok tits". Five of the six are thought to form a superspecies, with a distribution that extends over much of sub-Saharan Africa. As the **Mouse-coloured Penduline-tit** amply demonstrates, the plumage of *Anthoscopus* tends to be rather duller than that of *Remiz*. The six species range through uniform dull olive, grey or brown upperparts and whitish or yellow underparts.

[*Anthoscopus musculus*, Negele, Ethiopia.
Photo: Ketil Knudsen]

It may seem strange that an otherwise entirely Old World family should have a single member in the New World. Such a relationship is not borne out by the results of DNA-DNA analysis, which suggest that the **Verdin** is more closely linked to the gnatcatchers (Polioptilidae). Nevertheless, most taxonomists currently treat the Verdin as a monotypic genus within Remizidae. This distinctive, tit-like bird inhabits the deserts of the southern USA and Mexico. The predominantly grey-brown plumage of the adult is offset by a shocking golden-yellow head, and, to a lesser extent, by the bright chestnut lesser upperwing-coverts.

[*Auriparus flaviceps ornatus*, Saguaro National Park, Tucson, Arizona, USA.

Maslowski Productions]

bill, which has a more or less straight culmen, although the culmen of the Tit-hylia is slightly decurved and that of the Forest Penduline-tit is almost imperceptibly so. As with the tits and chickadees of the family Paridae, the nostrils are hidden by the feathers at the base of the upper mandible. The legs and feet of the majority of the remizid species are strong, but they vary among similar species and even among some subspecies. In the genus *Remiz*, for example, the strongest bill and legs are possessed by those species which prefer reedbeds, the Black-headed Penduline-tit being a particularly good example, whereas those species which prefer bushes, such as the White-crowned Penduline-tit, have markedly more slender legs.

Little external sexual dimorphism is apparent in this family. In all 13 species the sexes are basically similar to each other, but females are on average a little smaller than males. The greatest sexual difference in plumage is found among the Eurasian group of penduline-tits in the genus *Remiz*, but even here the sexes are often difficult to determine. Complications arise because first-year males can resemble females, and also because of the effects of plumage wear on the general appearance of the individual bird. The feathers of the head and breast have dark chestnut bases, but in fresh plumage these feathers have wide buffy or pale tips, concealing the chestnut colour; when the tips are abraded, the chestnut becomes visible as mottling on the sides of the breast and on the crown. This can confuse the unwary observer, especially in view of the plumage complexity of the different subspecies of the Eurasian and Black-headed Penduline-tits, as well as the additional plumages presented in the two zones of hybridization between these two species in the Caspian lowlands.

Whereas adult *Remiz* penduline-tits have a distinctively patterned plumage, with a usually prominent dark facial mask, the Afrotropical genus *Anthoscopus* consists of nondescript species, rather uniformly dull olive, greyish or brownish above and whitish or yellow below, with few distinguishing features. Juveniles of the Eurasian genus *Remiz* are distinct from the adults, being duller in plumage and having a plainer head lacking the bold pattern of the adult. In contrast, juveniles of the Afrotropical penduline-tits are very similar to the adults, but very slightly duller.

The aberrant Fire-capped Tit of Sino-Himalayan distribution and the Verdin of Middle American deserts are distinctive members of the family and bear little resemblance to the others. As already mentioned (see Systematics), the Fire-capped Tit is not unlike a *Phylloscopus* leaf-warbler in size and general olive and yellowish plumage coloration, and in some respects it is reminiscent also of *Anthoscopus*, but the male's red crown and throat in breeding plumage are highly distinctive. The female and the non-breeding male lack the red, although some females in spring display a hint of orange or reddish feathering on the forehead and chin. Juvenile Fire-capped Tits are virtually identical to the non-breeding adults. The Verdin is a small tit-like passerine, the adults' dull grey-brown and whitish plumage coloration relieved only by the dull mustard-yellow head and reddish-chestnut lesser upperwing-coverts. The female is similar to the male, except that her lesser coverts are browner and less bright, but this part of the plumage is generally concealed when the bird is at rest. Juveniles of this species are distinctive; they lack yellow altogether and appear grey, with a paler underside, and with the colour of the lesser coverts greatly subdued.

Finally, the tiny Tit-hylia differs from all other members of the Remizidae in its streaked head, throat and breast, its bright yellow to golden rump and belly and, not least, its bright yellow legs. The sexes are more or less identical, and the juvenile is relatively distinct, being somewhat darker above and having the throat and breast less clearly streaked.

Not surprisingly, all members of the family for which the relevant information is available have a complete post-breeding moult. In this, the primaries are replaced descendantly, from the innermost outwards. A post-juvenile moult is undertaken by the penduline-tits in the genera *Remiz* and *Anthoscopus*, although that of most of the *Anthoscopus* species is poorly known. The Verdin, too, has an incomplete post-juvenile moult. Apparently, southern populations of the Eurasian Penduline-tit sometimes have a complete post-juvenile moult. Moreover, observations suggest that some adult Eurasian Penduline-tits occasionally un-

dergo a partial pre-breeding moult, in the late winter or early spring, although further study is required in order to determine how widespread this phenomenon may be.

Habitat

In combination, the 13 species of the Remizidae inhabit virtually all major forest types. This is particularly so in Africa, where the six species of *Anthoscopus* hardly overlap at all in geographical range. The northernmost of these six, the Sennar Penduline-tit (*Anthoscopus punctifrons*), extends across a narrow belt of the deserts of the Sahel zone and the soudanian savannas from Mauritania eastwards to Eritrea, inhabiting desert scrub and stands of acacias (*Acacia*) in wadis. Immediately to the south, the little-known Yellow Penduline-tit (*Anthoscopus parvulus*) occurs in a band of semi-arid soudanian and northern guinean savannas from the Atlantic coast of Senegal east to south Sudan. In the acacias of north-east Africa, it is replaced by the Mouse-coloured

One of three monotypic genera in Remizidae, the

Fire-capped Tit is a taxonomic mystery of forests from the Himalayas to south-central China and northern Indochina. A tiny passerine weighing just 7 g, this species was previously thought to be a type of kinglet (*Regulidae*), and it shares a short tail and largely yellow-green plumage with that group. The Fire-capped Tit differs from all other members of Remizidae in that it nests in tree cavities, in the manner of tits and chickadees (*Paridae*); and it differs from all except the equally intriguing Verdin (*Auriparus flaviceps*) in that it lays blue, rather than white, eggs. These differences notwithstanding, there are good reasons for situating *Cephalopyrus* within this family. Its song is similar to that of *Remiz*, and it has the fine-pointed bill typical of other family members. It also shares several of the family's distinctive foraging techniques, such as using the bill to prise things open and reaching for food with its feet. Only the male has the red forecrown that led to the English and scientific names and, even then, only during the breeding season.

Photo: Kanit Khanikul]

Penduline-tit (*Anthoscopus musculus*) over most of Kenya and Ethiopia. Moving south, the lush lowland equatorial rainforests, extending from Liberia eastwards to DR Congo, are home to the Forest Penduline-tit and also to the Tit-hylia. East African broadleaf woodlands support a plethora of subspecies of the Grey Penduline-tit, whereas the more arid semi-desert and scrubby savannas of south-west Africa are favoured by the Cape Penduline-tit (*Anthoscopus minutus*).

In Eurasia, the genus *Remiz* provides for some interesting ideas on relationships, which have already been summarized (see Systematics). Suffice it to say that most of Europe, except for the north and north-west, now harbours breeding Eurasian Penduline-tits, which have invaded from eastern Europe and colonized central and western parts of the continent. This is the most northerly member of the genus, with a breeding range extending eastwards from south Scandinavia and the Baltic countries to western Mongolia and, in the south, to the north of the Caucasus, across Kazakhstan; the southern limit of its breeding range is in the Mediterranean region and west and east Iran. This species' eastern counterpart, the Chinese Penduline-tit, has increased dramatically in recent decades, at least in its non-breeding or passage areas; little is known of its breeding grounds, which lie chiefly in north-east China. Both species favour lakeside and riverine swampy vegetation and tidal marshes. They prefer a good mixture of emergent vegetation, including *Phragmites* reedbeds, with reedmace (*Typha*), poplars (*Populus*) and willows (*Salix*). The habitat choice of the Black-headed Penduline-tit is similar to that of the aforementioned two, but the White-crowned Penduline-tit differs from its three congeners in that it breeds in stands of poplars and willows beside lowland rivers and in floodplain meadows. It also breeds locally on bushy hillsides, and in orchards and walnut (*Juglans*) groves, and it can be found even in the Kyzylkum Desert, in Uzbekistan, where it nests in the saxaul (*Haloxylon*) scrub. The White-crowned Penduline-tit, when breeding, ascends as high as 2400 m in the western Tien Shan. In the winter months it utilizes equally as varied a selection of habitats, notably open forest, tamarisks (*Tamarix*), tree-lined embankments, reservoirs, and sometimes reedbeds. Interestingly, this species shuns reedbeds during the breeding season, but this habitat is popular among White-crowned Penduline-tits wintering in Pakistan.

Africa's smallest bird, the **Tit-hylia**, has bewildered taxonomists since its discovery in the mid-19th century. As a tiny, short-tailed inhabitant of the forest canopy, it was originally described as a flowerpecker (Dicaeidae), but has subsequently been placed variously in a remarkable seven different families! This monotypic genus has now come to rest within Remizidae, sharing similar nests, roosting habits and vocalizations with other remizids. The Tit-hylia differs, however, in its decurved culmen and brightly coloured legs. It may take genetic studies to reveal its true taxonomic affinities.

The remaining two species are both somewhat incongruous in terms of their habitat choice. The Verdin is a bird of desert scrub in the southern USA and the northern half of Mexico. It is especially fond of woody bushes and thickets growing along dry watercourses in low-lying flat desert, and it reaches elevations as high as 2135 m in Mexico. The other isolate is the Fire-capped Tit, which spends the breeding season high in Himalayan and Chinese forests, usually between 1800 m and 3000 m, post-breeding dispersal taking individuals up to 4300 m in south-east Xizang

The vocal talents of the penduline-tits are fairly unremarkable. The song of the male **Eurasian Penduline-tit** is a rather complex twittering, altering in pitch, and sometimes including mimicry of other bird species. Males tend to sing quietly while nest-building, but increase the volume upon detecting an approaching female. They will often sing from exposed songposts. The typical call of the genus *Remiz* is thin and high-pitched, but surprisingly penetrating. As such, it often offers the first clue as to the bird's presence.

in September. Western populations of the Fire-capped Tit breed in mixed broadleaf forests of oak, hazel (*Corylus*), elm (*Ulmus*) and walnut just below the coniferous alpine zone. In Ladakh, in north-west India, the species is found breeding in alpine scrub, as well as in orchards and stands of poplars, whereas the little-known eastern populations, in China, seem to prefer fir (*Abies*), spruce (*Picea*) and rhododendron (*Rhododendron*) forests. Western populations of this species descend in winter and can be seen in gardens and parks and in willow thickets by rivers and lakesides. Non-breeding visitors spend the season mainly on the plains of central India, where parks and gardens with stands of large trees in fruit or flower attract them.

General Habits

Of the 13 species currently included in the Remizidae, only three or four have been reasonably well investigated. Notable among the older studies is that on the White-crowned Penduline-tit in Transbaikalia and Mongolia carried out 80 years ago by Madame E. V. Kozlova. It is, however, the Eurasian Penduline-tit that has received the most attention, and a monograph on this species, written by M. Schönfeld, appeared in 1994. The fascinating variety of reproductive systems employed by this penduline-tit has been realized only through extensive colour-ringing undertaken by D. Franz and colleagues in the 1980s in Bavaria, in southern Germany, and at Lake Neusiedl, in east Austria. This species' breeding behaviour is discussed in greater detail later (see Breeding).

Eurasian Penduline-tits roost at night both solitarily and communally. Outside the breeding season, they normally roost in reeds or other suitably dense vegetation, such as willow thickets, but in the period preceding breeding they use the partly built nest for this purpose. One small flock was recorded as roosting in a hole in a wall. Early in the breeding season, in the valley of the River Main, in Germany, both local breeders and passage migrants were found to be roosting in reeds or thickets, even though the local breeders were already constructing nests several kilometres from the roosting site. Immediately after the nesting process is completed, the fledged brood, at first accompanied by a parent, gen-

erally sleeps at night in the nest, occasionally using the nest of another pair, or the family-members sometimes roost together in reeds. Little is known about the roosting behaviour of this species at other times of the year. In captivity, four individuals roosted solitarily in the early months of the winter, but later, in January, they slept together in a row, tightly huddled, very much as do Northern Long-tailed Tits (*Aegithalos caudatus*). This warmth-conserving behaviour diminished during February, and by mid-March had ceased altogether. In the Netherlands, wild-living Eurasian Penduline-tits were thought to be roosting in an old nest in December, but no confirmation of such behaviour has been obtained.

In Africa, the members of the genus *Anthoscopus* are basically similar to one another in behaviour, as typified by the Grey Penduline-tit. Unlike the *Remiz* species, they tend to avoid reedbeds and direct contact with wetlands, and are true forest birds. They forage actively in the tree canopy in pairs or in small parties, which are presumed to be family groups. Flitting from tree to tree, in follow-my-leader fashion, they inspect the foliage, sometimes achieving this by swinging upside-down in leaf clusters and flowerheads. Grey Penduline-tits will also feed much lower down, even descending to ground level at times, but chiefly when low-growing shrubs are in flower. Group-members keep in contact with each other by means of constant calling, and they readily associate with mixed foraging parties of other small birds, particularly white-eyes (*Zosterops*) and eremomelas (*Eremomela*).

Extensive studies of the closely related Cape Penduline-tit were made by C. J. Skead, who published the results in 1959. This species replaces the Grey Penduline-tit in semi-desert conditions, spending much of its time in low bushes, but only rarely is it seen on the ground itself. Cape Penduline-tits, too, freely join up with mixed parties of small birds, including Grey Penduline-tits in areas where the two overlap in range; somewhat oddly, however, although Cape Penduline-tits will join foraging Grey Penduline-tits, the latter seem not to join foraging groups of Cape Penduline-tits. The extraordinarily elaborate nest (see Breeding) is utilized also for roosting. Towards the end of the breeding season, two or possibly even three broods of Cape Penduline-tits will roost together with their parents in the nest. In one observed instance, a flock of 21 individuals tried to enter a

Most songs and calls of the genus *Anthoscopus* are variations on a rather prosaic theme, comprising repetitions of a single note. In the case of the **Cape Penduline-tit**, the high-pitched song is rather plaintive. It may be given either from a prominent perch, as here, or from deep within the canopy. The male may draw further attention to himself by performing a short display flight. Members of this species communicate with each other using two types of contact call, one rasping and the other ringing. They also utter a thin hiss, repeated several times.

Photo: Peter Ryan]

single nest; 18 of these succeeded, but three were obliged to roost elsewhere. Penduline-tits do not always use their own nests for roosting. Indeed, they often appropriate the disused nests of various species of weaver (Ploceidae) for this purpose.

The peculiar Tit-hylia was originally described as a flowerpecker (see Systematics), and it has much in common with the members of that family. Like them, it is a difficult species to study owing to its tiny size and its habit of foraging high in the canopy of tall forest trees. It travels in small parties of up to seven individuals, flying directly from one tree to another. It moves quickly as it gleans food items within or beneath the foliage, concentrating its effort at bunches of leaves or clusters of flowers. Like the flowerpeckers, it is fond of mistletoe (Loranthaceae) clumps and vine tangles, through which it hops, flicking its wings while peering under leaves and pecking at bark crevices. Because of its tiny size, it sometimes becomes caught up in spider (Araneae) webs. The Tit-hylia is a communal rooster, with up to five individuals reported sharing a nest at night after the end of the breeding season.

In complete contrast to the above-mentioned species, the Verdin is a desert specialist that has to endure extreme temperatures. These range from about 35°C, and occasionally as high as 45°C, in the daytime to below freezing at night, and it is not surprising, therefore, that the Verdin goes to roost early and leaves relatively late in the morning. It is said that, in its harsh desert habitat, it does not drink water; presumably, it is able to acquire sufficient moisture from its diet. The Verdin has received a fair amount of attention, culminating in several papers by W. K. Taylor, in the 1970s, and M. D. Webster's monograph, in 1999. Verdins are usually encountered in pairs or in small family parties, holding both winter and breeding-season territories. They often join mixed-species flocks, but perhaps only when these are moving through the Verdin's territory. This species keeps mostly to bushy cover, preferring not to show itself in the open. It forages through foliage and searches the flowers of desert shrubs, inspecting the bark and leaf clusters by swinging upside-down in tit-like fashion. It utilizes one of its strong feet to pull twigs or leaves towards itself for closer inspection. Each individual builds a number of roosting nests throughout the territory, the two sexes acting independently and not assisting each other, but males build more of these nests than do females. Roost-

ing nests are often smaller than those used for breeding; they tend to be built around a branch fork, and to have a shallower cup and more centrally placed entrance. The adults do not roost together, but the fledged young often occupy a roost nest with one of their parents.

Finally, the kinglet-like Fire-capped Tit possibly bridges the gap between the true tits in the family Paridae and the penduline-tits. It is a sociable species in winter and during migration, and small groups are not unlike Oriental White-eyes (*Zosterops palpebrosus*) in behaviour as they move from tree to tree, foraging with other small birds in the upper canopy of fruiting trees. Fire-capped Tits search for insects in the middle and upper canopy of tall trees, and on passage often in riverine bushes, too. They are usually found in small parties, but considerable gatherings of 100 or so individuals have been reported. Flocks sometimes gather on bare trees on hillsides, when they can be reminiscent of tiny finches (Fringillidae). The species regularly joins with mixed parties of other small birds, especially outside the breeding season. The Fire-capped Tit forages in tit-like fashion, swinging upside-down to investigate leaf bunches, and it climbs along the underside of branches, peering into nooks and crannies. Although it feeds with great agility, it seems to "walk" with a deliberate gait, rather like a tiny parrot (Psittacidae), sidling along twigs to "haul in" rolled leaves with the bill. Then, while holding the leaf securely under the foot, it prises open the leaf roll.

Little is known of the maintenance and comfort behaviour of the Remizidae. In the Afrotropics, the Grey Penduline-tit has been observed to bathe by shuffling among short tufts of wet grass, thereby soaking its plumage, and then to fly back up into a tree in order to preen, and the Tit-hylia has been seen to bathe by brushing its plumage against wet leaves. Elsewhere, sun-bathing has been recorded for the Eurasian Penduline-tit, which adopts a spread-eagle posture as it absorbs the sun's rays.

Voice

The penduline-tits are not renowned for their vocal ability. Nevertheless, the distinctive "seeeoouu" given by members of the genus *Remiz* is often the first indication of the bird's presence. This call, thin but remarkably penetrating and reasonably far-

In the calm of the desert dawn, the rather simple song of the Verdin is an efficient means of communication, as it is audible over a considerable distance. The song consists of a series of plaintive whistles, varying in volume and number, admixed with brief twittering. In contrast, the typical Verdin call is a rather sharp note that is sometimes run together into a harsh, abrupt chatter. Pairs and family parties also keep in contact using a weak contact call. This meagre vocalization is all that is required to communicate in the sparse woody bushes and thickets that form the Verdin's habitat.

Small invertebrates provide the bulk of the diet of all penduline-tits.

Members of the genus *Remiz* mainly consume insects and their larvae, as well as spiders

(Araneae). However, they also make the most of other food sources offered by their habitat. **Chinese Penduline-tits** will feed on the seeds of willows, poplars and reedmace.

When foraging in reedbeds, they use the strong, sharp bill to good effect, breaking into hollow reed stems and prising apart crevices in order to extract invertebrates that lurk within. Like at least two other members of the genus, the Chinese Penduline-tit is relatively sociable outside the breeding season, sometimes forming quite large flocks during migration periods and in winter.

Ferdinand]

carrying, is given also in flight as a contact note among individuals in migrating parties. Eurasian Penduline-tits have a rather complex song, rising and falling in pitch, which consists of finch-like trills and twittering phrases interspersed with call notes. The song varies somewhat in intensity. The male emits a subdued song while nest-building, but breaks into a more elaborate version when a prospecting female arrives near the partially constructed nest.

Members of the genus *Anthoscopus* have songs and calls based on the repetition of single notes. The Cape Penduline-tit utters a high-pitched and often plaintive "chawee, chawee" or "tseewee, tseewee", repeated six to eight times from a perch or from inside the canopy. At the height of its song it often takes wing in a short courtship flight, uttering an abrupt "zwayt" as it does so. In the acacia savanna in north-east Africa, the Mouse-coloured Penduline-tit utters a rapid rattling trill reminiscent of the sound made by a tinny machine-gun, which is not too far removed from the rhythmic mechanical buzzing of both the Sennar and the Yellow Penduline-tits of Central African savannas. The song of the widespread Grey Penduline-tit is rather variable, the differences possibly being of taxonomic significance. As an example, the East African subspecies *sylviella* has a song described as a thin, yet metallic trill lasting some 2–3 seconds, whereas that of the west Tanzanian race *pallascens* is said to be a high-pitched trill which slowly fades. Most populations of this species utter a short phrase, repeated three or four times, consisting of a prolonged rising note, often preceded by two to four short ones; these can be delivered as a deep rasping "chi-chi-ch-dzzayzza"

or similar, or as a much sweeter, weaker "tsi-tsi-cheweeeee". In contrast, the Forest Penduline-tit of West and Central Africa utters a high-pitched song very much like the sound made by a cricket (Orthoptera) and therefore easily overlooked as coming from an insect; as a consequence, this penduline-tit is a poorly known species. Interestingly, the other rainforest-dwelling member of this family, the Tit-hylia, also produces a remarkably insect-like trill, although its song is relatively loud and is preceded by three or four whistled notes.

When advertising its presence in desert scrub, the Verdin relies on vocalizations. Its loud, plaintive, whistled "tswee, tswee, tswee, tsweet" carries over long distances in the early-morning desert silence. There is some variation in the number of notes and the strength of delivery, and the song may be intermingled with other notes, including short twittering phrases. The Verdin's usual call is a sharp, loud "chip" or "tschk", which has been likened to the sound produced when two ball-bearings are knocked together. This call is sometimes repeated such that it forms a rapid, staccato chatter.

The Fire-capped Tit's song is a prolonged repeated series of short trills and twittering sounds, seemingly a couple of phrases repeated at different speeds and pitches. It can be given during a short song flight, but the songster prefers to deliver its message from the very top of a tall tree, from which the song rises and falls for several minutes. This species' contact calls include a soft and mellow "whitoo-whitoo", and a high-pitched and abrupt "tsit" which is often repeated. Flocks in winter keep up a persistent twittering, and the human observer, if he or she does not ob-

Penduline-tits are active foragers, constantly on the move and investigating potential food sources. Members of the genus *Anthoscopus* inhabit woodland or forest, and are equally at home feeding in the canopy or lower down, in bushes or even shrubs. The diet of the better-studied species mainly comprises insects, including their eggs and larvae. The **Cape Penduline-tit** fits the mould, but also takes small spiders (Araneae), small fruits and small seeds. This species mainly provisions its young with the larvae of butterflies and moths (Lepidoptera) and beetles (Coleoptera). It has also become somewhat of an expert at breaking into plant galls, to extract the larvae of gall-causers (Cynipidae).

[*Anthoscopus minutus*, West Coast National Park, Western Cape, South Africa. Photo: Peter Ryan]

tain a good view, could confuse these with flocks of Tibetan Serins (*Serinus thibetanus*).

Food and Feeding

The diet of penduline-tits consists primarily of small invertebrates. This is especially so during the breeding season, when young birds require a high-protein food supply. Particularly important are small spiders and their cocoons, non-hairy caterpillars and small beetles (Coleoptera). Members of the genus *Remiz* feed also on the fluffy seeds of reedmace, poplars and willows, plants that are generally prominent in the habitat occupied by these birds (see Habitat). They peck at and pull apart the cylinder of reedmace seeds, which are especially important in the winter months. In late summer, Eurasian Penduline-tits switch to foraging in reedbeds, where they take advantage of the seasonal abundance of the mealy plum aphid (*Hyalopterus pruni*), which forms a particularly important component of the bird's diet at this time of the year. The conical, sharply pointed bill is well designed for prising open small objects or small cracks; the penduline-tit inserts the tip of the bill into a small crevice and then forces the mandibles apart. Hollow reed stems provide ideal hibernation sites for many small invertebrates, particularly larvae and pupae of Lepidoptera, and the sharply pointed bill can break into the stems with ease. The Eurasian Penduline-tit forages in the foliage of the outermost branches of poplars and willows; in spring it visits the flowers of willows, perhaps because they attract insects, but penduline-tits may feed also on nectar. Often, a feeding individual holds a willow catkin or a tuft of reedmace seeds in its foot while it breaks into the seeds. It will hold down caterpillars in a similar manner, and decapitate them before swallowing the food.

All of the African species, in the genus *Anthoscopus*, are purely woodland or forest birds, but they feed in a manner similar to that of *Remiz*. They seem, if anything, to be even more active, flitting from tree to tree, often probing while hanging up-

side-down, inspecting crevices in the bark and investigating leaf clusters and flowerheads. The Grey Penduline-tit has a largely insectivorous diet, which sometimes includes ticks (Ixodidae); it augments its diet with small fruits, and it probes the flowers of mountain aloe (*Aloe marlothii*) for nectar. The Cape Penduline-tit, which inhabits dry, semi-desert scrubby country, has developed a habit of breaking into galls of prickly shrubs in order to reach the larvae of the gall-causer inside. It also takes small fruits, such as those of bony-thorn (*Lycium*), and small seeds have been found among the stomach contents of specimens. This species will use its foot to hold larger food items, which it then rips apart.

The Tit-hyllia feeds almost entirely on small invertebrates, especially insects. A good proportion of its food items consists of the hemipteran bugs known as scale-insects (Coccoidea), but small seeds have been found in stomach contents of this species, too. Similarly, Fire-capped Tits are almost entirely insectivorous, although they do consume a certain amount of vegetable material. They have been observed to eat flower buds and young leaves, and they also take the juice or sap exuded from banyan (*Ficus*) leaves. This species holds larger prey items in its foot, extracting the soft contents and discarding the empty "case", but it has not been reported as breaking up an entire item in the manner of parid tits.

The Verdin's diet is made up mostly of insects and spiders, but in autumn and winter small berries are an important additional component, especially as this desert-inhabiting species is said not to drink water. Verdins use their strong toes to grip twigs or leaf buds and then to pull these towards themselves and inspect them. They hold down caterpillars and spider cocoons under the foot, breaking up food items and consuming the lot, as parid tits do.

Breeding

The penduline-tits are named for the incredibly intricate, rather pendulum-shaped nests that they construct. When complete,

the nest has the appearance of an almost pear-shaped felt bag, woven from spiderweb, wool and soft downy plant materials. It is extremely strong and long-lasting, and is attached by means of twigs, which pass through the narrowing "handle" of the nest top.

In Africa, the Cape Penduline-tit is the most studied of the Afrotropical genus *Anthoscopus*, the members of which, it seems, construct nests even more elaborate than those built by the Eurasian species of the genus *Remiz*. Cape Penduline-tits have reduced the possibility of nest predation by incorporating, below the true entrance and nest-chamber, a false entrance leading to an empty false chamber. Entry to the true chamber is by way of a concealed entrance flap; the bird opens the flap, using its foot for this purpose, enters the chamber and closes the flap, which it then seals "Velcro-fashion" with sticky spider webs. The mouth of the false chamber is particularly thick and strong, and this makes it useful as a platform on which the bird can brace itself while opening the "secret door" into the real nest-chamber. This elaborate nest is built by both sexes, in a period of 20–35 days; if the original nest is destroyed by a predator or by storms, however, a replacement can be produced more quickly, in 13–20 days. During construction, when both adults are searching for materials, the nests are likely to be raided by other small birds, especially sunbirds and the larger members of the finch genus *Serinus*, seeking material for their own nests, sometimes to the point that the tits abandon their nest entirely.

With two exceptions, the members of this family lay white eggs. In the case of the Cape Penduline-tit, the clutch contains from four to eight eggs; very rarely, nests of this species hold as many as ten or twelve eggs, but these apparently large clutches are perhaps the product of more than one female. Incubation is undertaken by both sexes, with change-over at the nest taking place every 30 minutes during the day, and the total duration of incubation is 15 days. Both sexes feed the nestlings, chiefly with insect larvae, and they are sometimes assisted by helpers. The youngsters leave the nest at 22–24 days.

It is not only the nests that make these birds so extraordinary, but also their varied mating systems. Although monogamy

prevails, a good proportion of the population of some of the Remizidae are polygamous and even polyandrous. This is true in the case of the well-studied Eurasian Penduline-tit, and perhaps applies to other members of the genus *Remiz*. Extensive colour-ringing of Eurasian Penduline-tits, carried out by Franz and colleagues in the 1980s in south Germany and east Austria, has provided this insight into the complex variety of mating systems employed by this species. In contrast, the Cape Penduline-tit is monogamous but receives assistance from helpers, these being younger birds from previous broods of the pair in question. In a study of several breeding units, eleven consisted of a single pair, two were trios and one was a group of four individuals.

With the Eurasian Penduline-tit, nest-building is initiated by the male in an attempt to attract females, but sometimes pairing has already taken place before the construction work begins. On other occasions, an unmated male may partially construct five or six nests, up to the basic framework, the so-called "basket" stage, before a female arrives on the scene. The partners may stay together to complete the nest, the female incubating as the male continues with the building work, but sometimes the female chases the male away after mating, and she then takes over the remainder of the task of nest construction. In the latter instance, the male then moves on to begin another nest, usually after one or two days' "rest" from nest-building. Male Eurasian Penduline-tits may eventually incubate and rear one of these broods alone, as the females of this species are equally promiscuous and may mate with up to six males in one season. The building of the first nest of the season takes 15–24 days, but subsequent nests can be completed in as little as six or seven days.

The little Tit-hylia has not yet been well studied, in good part because it is an inconspicuous bird of the forest canopy. It is believed to be primarily a monogamous solitary nester, but it is, at least sometimes, a co-operative breeder. In Angola, four individuals of this species were observed as they combined to build a nest, and later two young at the site were watched as they were fed by four adults. The Tit-hylia's nest is rather large

In common with other remizids, the **Verdin** is an agile forager, reminiscent of the tits and chickadees of the Paridae. Swinging upside-down, the bird clasps a leaf, bud or twig in its foot, manoeuvring it into a position suitable for inspection. The Verdin's most frequent quarry is a small invertebrate, particularly an insect or a spider. Large prey items, such as some caterpillars, are held with one foot, then dismembered and consumed; such behaviour again recalls the parid tits. During autumn and winter, the Verdin supplements its diet by taking small berries; these have the additional benefit of providing water, which is important for a desert species that is thought not to drink.

The Early Birder]

The *Tit-hylia* forages in small groups high in the rainforest canopy. These energetic feeders fly rapidly between trees to explore clumps of dense vegetation such as leaves, flowers and vine tangles. Here the *Tit-hylia* searches intently under lichens or leaves and probes crevices, trying to find the small invertebrates that feature strongly in its diet. Scale-insects (*Coccoidea*) are a particular favourite, but the discovery of seeds in the stomach contents of specimens suggests that the *Tit-hylia* is not entirely carnivorous. Like the flowerpecker family (*Dicaeidae*) in which the *Tit-hylia* was previously placed, this species frequently forages amidst *Loranthus mistletoe*. Unlike the case of flowerpeckers, however, there is no evidence that it eats mistletoe berries.

[*Pholidornis rushiae denti*, Bwindi-Impenetrable Forest National Park, Uganda. Photo: Ketil Knudsen]

for the size of the bird. It is a ball 15 cm in diameter, made of felted soft plant materials, with an entrance spout pointing vertically downwards. Unlike the nests of the *Anthoscopus* penduline-tits, there is no false chamber. Nevertheless, it is very well made, and is strongly bound to a branch or mass of twigs, and on one occasion a nest of this species was reported as having been built into the old nest of a *Ploceus* weaver.

The Fire-capped Tit differs from all others in the family in that it nests in tree holes. It is an inhabitant of montane forests in the Himalayas and south China, where it prefers to utilize old holes made by barbets (*Capitonidae*) and woodpeckers (*Picidae*) in trees. In some cases, it will excavate or enlarge a small hole in soft or rotten wood. Unlike many of the true tits, which use a lot of material to fill deep holes, the Fire-capped Tit makes a simple cup of rootlets and dry grass, which it lines with feathers and finer grasses. It seems that the female alone builds the nest, although the male often accompanies her and not infrequently sings nearby. This species and the Verdin are the only members of the family to lay blue-green eggs, rather than white eggs. The average clutch of the Fire-capped Tit consists of four eggs, which is a very low figure compared with that of many of the parid tits. Although the incubation and fledging periods are not known, it appears that only the female incubates. She sits tightly and, if a potential predator attempts to enter the nest-hole, she puffs herself up and hisses, this behaviour being exhibited also by the true tits of the family *Paridae*.

So far as is known, the Verdin is monogamous. Both sexes take part in the constructing of the nest, although it is the male that initiates the work. The female becomes most actively involved towards the end of the process, particularly with regard to the lining of the cup. The elaborate nest is a large globe, up to 20 cm across, with as many as 2000 spiny twigs woven into it and around the supporting branches, these twigs being placed with the thorns facing outwards in order to deter potential predators. This complex structure is built in several stages, beginning with a platform of soft materials woven through the supporting twigs, followed by a dome, inside which is the soft lining of feath-

ers, often with some fur and wool. The twigs and spines are interwoven with a variety of soft materials, including feathers, cobwebs, soft seed pods, wool and leaves. The entrance hole is at the side of the nest, obscured by a projecting awning of twigs. Typically, this striking nest is situated up to 3 m above the ground near the end of a low branch of a thorny desert shrub. During the course of its construction, the pair may take materials from old nests, including the relatively large number of roost-nests built by this species, and this perhaps explains why the completion of the nest can require only 4–6 days.

Together with the Fire-capped Tit, the Verdin has a relatively small clutch size, laying only three or four eggs. These are similarly blue-green but, unlike those of the Fire-capped Tit, are finely speckled with reddish. Although only the female Verdin incubates, for a period of 14–17 days, both sexes feed the young, the female taking on the greater share of this duty during the first week. The young leave the nest at 17–19 days of age, but they are still fed by their parents, chiefly the male, for a further 18 days or so. In the meantime, the female settles down to laying another clutch of eggs, as this species produces at least two broods in a season.

Movements

The Verdin, the *Tit-hylia* and several of the Afrotropical penduline-tits are, so far as is known, sedentary. In complete contrast, all of the species in Europe and Asia are strongly migratory, although some populations of both the Eurasian Penduline-tit and the Black-headed Penduline-tit remain in their breeding areas during milder winters. Both Eurasian and Chinese Penduline-tits, the two northernmost species, have undergone massive population and range increases in recent decades, although the source of the large and increasing numbers of the latter is still unclear, as the known breeding sites of Chinese Penduline-tits are relatively few. These two species are long-distance diurnal migrants, moving overhead in small parties.

This male **Eurasian Penduline-tit** has made sufficient progress with building a nest that he has attracted a female (right) to investigate. The nest is at the so-called "basket" stage: the framework is in place, with the pouch hanging from a "handle" that is sturdily attached to the smaller twigs of a tree or bush, or between reed stems in a reedbed. The pendulum-shaped nests give rise to the penduline-tits' English name. Nests in trees tend to be 3–4 m above ground, whereas those in reedbeds will be only a metre or so above ground or water. If the female is satisfied with the nest as presented, she may mate with the male, then either chase him away or let him leave. The female then finishes building the nest on her own, and the male, after a couple of days' break, constructs another nest framework, with which to attract another female. The process may unfold several times, but with a twist. The Eurasian Penduline-tit is not merely polygamous; the species is also polyandrous, females mating with up to six males in a single breeding season. The female may desert the nest once she has laid the eggs and leave the male to incubate and raise the brood alone.

Eurasian Penduline-tits breeding in eastern Europe move south or south-west to their winter quarters, which lie chiefly around the northern and western shores of the Mediterranean Basin, a few individuals reaching the coast of north-west Africa. Juveniles are the first to move out of the breeding areas, most of these leaving from mid-July onwards; a feature of this is a random dispersal northwards, as well as the main migration to the south and west. Adults tend to move out in the first half of August, passage through Germany being recorded from late September to November. Some overwinter at Lake Neusiedl, in east Austria, and vagrants have occasionally spent the winter months in England, but more notable is the significant winter population of up to 500 Eurasian Penduline-tits in lagoons by the Baltic coast of Latvia. Breeding populations from farther east, across south Russia to east Kazakhstan, migrate to non-breeding areas in southern Turkey and eastwards across Iraq and Iran. In addition, surprisingly large numbers have been recorded flying south through Israel to an as yet unknown wintering area, presumably somewhere in north-east Africa. In Europe, spring passage of this species can begin as early as February, passage through central parts, such as Switzerland, reaching a peak in the first week of April but continuing until mid-May.

The Eurasian Penduline-tit's Central Asian counterpart is the Black-headed Penduline-tit, which is less strongly migratory, although it seems likely that its northern and eastern populations move west or south-west to non-breeding grounds in the Caspian lowlands of north Iran. Some, however, remain as far north as southern Kazakhstan, and two winter specimens from Israel have been identified as hybrids between Eurasian and Black-headed Penduline-tits of the type known as "*altaicus*", originating from the Caspian region (see Systematics). As large numbers of Eurasian Penduline-tits of the subspecies *caspius* spend the winter months in Israel, it seems likely that some Black-headed Penduline-tits could occur with them, and observers should look out for the latter also in south Iran and Iraq. Indeed, there is a sight record of a "black-headed" penduline-tit at Muscat, at the entrance to the Persian Gulf, on 29th March 1971. Even in Central Asia, the spring passage of the Black-headed Penduline-tit begins early, with reported movement through Turkmenistan from late February into early March, and through Tashkent, in

This male **White-crowned Penduline-tit** is putting the finishing touches to a nest. Both sexes build the nest, but once the basic structure is in place, the female switches duties to egg-laying and incubating, while the male completes construction. As in other Remiz species, the nest is a rather long globular pouch, with a downward-pointing entrance tube to one side. It is made of woven plant fibres and down from trees such as willow (*Salix*) and poplar (*Populus*). The nest hangs 6–8 m above ground from the end of a horizontal tree branch.

[*Remiz coronatus coronatus*, near Chilek, east of Almaty, Kazakhstan. Photo: David Fisher]

Uzbekistan, from mid-March to early April. The autumn passage in these regions takes place from late September until the start of the winter.

White-crowned Penduline-tits arrive on their breeding grounds in Mongolia in late May and early June, departing again in September and October, and a similar picture prevails in southern Siberia and Kazakhstan. The entire population of this species is migratory, although, in mild winters, a few remain in the lower-lying parts of Uzbekistan and Tajikistan. Migrants pass through

This **Verdin** is safely tucked away within its nest, where it may be incubating. The Verdin is monogamous, and both partners play a role in building the nest. The male does the bulk of the early work, the female becoming involved towards the end, taking particular responsibility for the soft lining of the cup. The nest is a striking construction, up to 20 cm in diameter, with as many as 2000 spiny twigs woven together into a dome. The spines are deliberately placed towards the outside so as to impede the approach of potential predators. Remarkably, the nest takes just 4–6 days to build, in part because the birds take material from old nests or roosting nests.

[*Auriparus flaviceps ornatus*, Tucson, Arizona, USA. Photo: Rick & Nora Bowers/VIREO]

Members of the Afrotropical genus *Anthoscopus* construct remarkable nests that eclipse even those of the genus *Remiz*. The nest is a strong, durable felt bag, almost pear-shaped and intricately woven from soft plant materials, wool and spider webs. This sturdy construction would probably be enough in itself to deter predators, but members of *Anthoscopus*, such as this **Grey Penduline-tit**, go one step further. By furnishing the nest with an obvious entrance hole, they entice potential predators into what transpires to be a false nest chamber. To access the real nest chamber, the penduline-tit opens a concealed entrance flap or "hidden door" with its foot, enters the chamber, and re-seals the flap with sticky spider webs.

[*Anthoscopus caroli hellmayri*, Stone Hills Game Sanctuary, Zimbabwe. Photos: J. R. Peek]

south-west Turkmenistan en route to non-breeding grounds in east Iran and south-west Afghanistan, where they are present from November to February. Small parties recorded in March in Xinjiang, in north-west China, although initially suggestive of breeding, were probably also on passage. Small wintering flocks arrive in Pakistan from as early as late September in some years, but the majority do not reach that country until December, remaining there until the end of March. On spring passage, White-crowned Penduline-tits have been recorded from mid-March to mid-April farther north in Pakistan, and a few penetrate to the borderlands of north-west India. Elsewhere, a vagrant of this species was trapped on 1st August 1987 at Lake Neusied, in Austria, and it is likely that others reach Europe, and perhaps especially the Near East, where Eurasian Penduline-tits from the north Caspian region are known to occur.

Chinese Penduline-tits are present on their breeding grounds in north-west Jilin from mid-April until late September, and are recorded from late April in south Liaoning, where they may be only passage migrants. This species is fairly common on spring migration through North Korea in April and May, but in nearby South Korea small numbers are present in the non-breeding season, from October to May. The Chinese Penduline-tit appears to migrate on a narrow front through north-east China, its main wintering areas lying along the middle and lower reaches of the River Yangtze, in eastern China, and along the River Nu Jiang, in west Yunnan; increasingly, small numbers can be found in winter at the Mai Po Marshes, in Hong Kong, from November to mid-April, some remaining into May. Since the 1970s, this member of the family has become a locally not uncommon winter visitor to Kyushu and Honshu, in south Japan, and in March 1987 a vagrant was recorded farther south, on Okinawa, in the central part of the Ryukyu chain of islands.

The Fire-capped Tit is an altitudinal migrant, the western, nominate race moving farthest, but the distributional division of the two subspecies in the Nepalese Himalayas is uncertain. Those in the Western Himalayas arrive on their breeding grounds from late March to mid-April, departing again in late August and through September, although few are reported in autumn. This apparent scarcity in autumn is no doubt due to the lack of red on the fresh-plumaged males at that time of the year, rendering them more inconspicuous. Some may remain in the foothills, but the majority spread out over the Indian plains from south Uttar Pradesh and east Rajasthan south through much of Madhya Pradesh. The eastern subspecies, *olivaceus*, is less well known but it seems to move to the foothills of the mountains for the winter, although some do stray farther. There are reports of small parties of Fire-capped Tit appearing as vagrants in the southern Shan States of Myanmar, in north-west Thailand and in north-west Laos.

Finally, the Afrotropical members of the family are more sedentary, but doubtless most species do make movements of varying extent subject to local conditions, such as drought or the intensity of seasonal rainfall. This may apply only at the edge of a species' range, and not over the whole of it. The Yellow Penduline-tit is a good example. This species visits the coastal forest regions of Senegal, Gambia and Mauritania only during the wet season, retreating inland as the dry season advances. In Ghana, it seems to have disappeared from the Mole National Park by the height of the dry season, whereas it is common there during the wet season, from May to September. In contrast, no such seasonal fluctuations have been reported for this species in Nigeria. Similarly, the widespread Grey Penduline-tit is very sedentary, but it does move around according to local conditions. In the austral winter it descends into the Zambezi valley of Zimba-

bwe, and in Kenya its sporadic appearance at Lake Baringo suggests that dispersal of individuals is a regular habit of the species.

Relationship with Man

Penduline-tits have little direct contact with man, although the Eurasian Penduline-tit has increased dramatically since the 1950s, aided partly by changes in habitat and riverbank management (see Status and Conservation). It is, of course, the nest which has always attracted the attention of humans. Indeed, nests of Eurasian Penduline-tits were in earlier times often used as children's slippers in parts of Central Europe. In the equatorial forests of West and Central Africa, the nests of Forest Penduline-tits were traded as curios to European explorers.

Otherwise, any influence that these passerines have had on human beings is minimal. They are popular among birdwatchers, but it seems unlikely that other people would even be aware of their presence, except, perhaps, for wondering what could be the source of some of the vocalizations uttered by the Remizidae (see Voice).

Status and Conservation

None of the 13 members of the family is considered to be globally threatened, and all are deemed to have ranges sufficiently extensive to ensure the survival of the species. There is, nevertheless, some cause for concern over certain populations in Central Asia and southern Siberia. The White-crowned Penduline-tit no longer occurs in the Minusinsk Depression, having been lost as a result of intensified economic development. Similarly, some populations of the Black-headed Penduline-tit have no doubt been eradicated through massive irrigation schemes, causing the drying-up of the Aral Sea, but the main concern with this species centres on the distinctive dark race *nigricans*, restricted to the Sistan depression, in south-east Iran. This subspecies has not been seen for many years, and it may well be extinct, but there is a possibility that it could survive unrecorded in adjacent south-

west Afghanistan, where the massive lake of Hamun-i-Puzak, a Ramsar site, holds permanent water and formerly had extensive reedbeds. On the other hand, periodic droughts in this region of Afghanistan, and reed-cutting by villagers, must have had a negative impact, although the most serious threat is the proposal to build a paper factory in nearby Helmand Province, using reeds as raw materials. It remains to be seen whether or not this proposal will become a reality.

The status of the Chinese Penduline-tit is more encouraging. This remizid has shown a remarkable increase in its populations both on migration and in winter, and it has extended its non-breeding range into southern Japan and south to Hong Kong. The whereabouts of its main breeding grounds, however, remain something of a mystery.

Although none of the African species is currently under threat, certain subspecies of the Grey Penduline-tit are poorly known. This is particularly the case with the distinctive richly coloured race *rankinei* of north-east Zimbabwe, which could possibly represent a separate species and is in particular need of taxonomic investigation (see Systematics). The future of two other Afrotropical species, the Sennar and the Yellow Penduline-tits, seems reasonably bright, as, unlike many specialized small birds, they appear to tolerate habitat degradation caused by chopping for firewood and overgrazing by domestic animals, particularly goats. The larger Forest Penduline-tit and the diminutive Tit-hylia are reasonably widespread, but knowledge of various aspects of their lives remains rather poor. Indeed, the south-east DR Congo race *ruthae* of the Forest Penduline-tit is known from just two specimens and less than a handful of field observations. These inhabitants of lowland rainforest have suffered through excessive tree-felling; they do need forest clearings with flowering trees.

Of the remaining members of the family, only the eastern subspecies of the Fire-capped Tit seems poorly known, this being particularly true in respect of its non-breeding distribution. It is probable that it winters in foothill forest, rather than, entering the Indian plains as does the western race (see Movements).

Since the 1950s, the Eurasian Penduline-tit has increased dramatically, partly as a result of changes in habitat management

This adult **Verdin**, probably a male judging by its chestnut lesser upperwing-coverts, is feeding a nestling. Clutch size in this species is 3-4, but pairs usually make up for this relatively low number by raising two broods per breeding season. The female incubates the eggs alone for 14-17 days. When the eggs hatch, she provides most of the food during the first week, after which the parental balance is more even. When 17-19 days old, the young fledge. They remain dependent on their parents for a further 18 or so days. The male shoulders most of the responsibility for feeding, leaving the female free to lay a second clutch.

[*Auriparus flaviceps acaciarm*, Anza Borrego Desert State Park, California, USA. Photo: Rob Curtis/The Early Birder]

Bringing food to a hungry brood is just one parental task for the **Eurasian Penduline-tit**. It is also the adult's job to keep the nest clean and thereby minimize the risk of disease. An important task is the removal of the faecal sacs excreted by the chicks, which would otherwise build up inside the nest, with the consequent health risks. The adult collects each sac and flies rapidly and discreetly away from the nest, depositing it sufficiently far away to avoid its attracting predators to the brood.

made by humans. The spread of fish farms and gravel pits, and the creation of lakes by subsidence from mining, as well as open-cast mining, have all helped to provide better habitats for this species. The eutrophication of lakes and slow-flowing rivers has permitted the growth of many plants that provide penduline-tits with materials, such as hops (*Humulus*) and nettles (*Urtica*), for nest construction. It is possible that similar factors may lie be-

hind the increase in numbers of passage and wintering Chinese Penduline-tits, mentioned a few paragraphs above, but, as stated, the breeding grounds of this species are scarcely known. Another positive factor, this time in parts of Africa, has been the the planting of cotton. This has provided a welcome source of nesting materials for some of the *Anthoscopus* species.

Patchily common over most of its range, the sole New World member of the family, the Verdin, is thought to have increased in Arizona and north-west Mexico along with the spread of mesquite (*Prosopis*) scrub. In the north-east parts of its range, however, it is rare. The large number of nests which each pair produces can create a false impression of abundance, making this a very difficult bird to census. Nevertheless, it is considered not to be at any risk.

This brood of five young **Eurasian Penduline-tits** appears to be in the process of leaving the nest; indeed, one juvenile has already ventured outside the increasingly cramped confines of the nest. The nest entrance tunnel has fallen off, presumably as a result of the chicks' movement.

The birds are thus exposed to the elements, and the nest no longer provides effective protection. Once the young have left the nest, they continue to be fed by a parent for a further fortnight before becoming independent. In late summer, neighbouring broods may join together into loose foraging flocks of 20–30 juveniles.

[*Remiz pendulinus pendulinus*, France.
Photo: Frédéric Fève/Bios]

Genus *REMIZ* Jarocki, 1819

1. Eurasian Penduline-tit

Remiz pendulinus

French: Rémiz penduline **German:** Beutelmeise **Spanish:** Pájaro-moscón Europeo
Other common names: Penduline Tit, Common/European/Masked/Western Penduline-tit

Taxonomy. *Motacilla pendulinus* Linnaeus, 1758, Poland, Lithuania, Hungary and Italy. Forms a species group with *R. macronyx*, *R. coronatus* and *R. consobrinus*, and all four often combined as one species; sometimes present species considered conspecific with *R. macronyx*, and the other two united as a separate species. Treatment as four distinct species based mainly on structural, as well as plumage and habitat, differences. Present species frequently hybridizes with *R. macronyx* by N & SW shores of Caspian Sea; hybrids in N (mouth of R Ural) named as *bostanjogli*, and those in S as, respectively, *loudoni* and *altaicus*; last-mentioned sometimes treated as a valid race. Birds of this species in Syria (and possibly extreme N Israel) of uncertain racial identity, provisionally placed in *menzbieri*. Additional proposed races are *persimilis* (described from Ereğli, in S Turkey), which is synonymized with *menzbieri*, *castaneus* (from Astrakhan), included in *caspius*, and *barabensis* (from Baraba and Kulunda steppes, in Tomsk area of W Siberia), treated as a synonym of *jaxarticus*. Four subspecies recognized.

Subspecies and Distribution.

R. p. pendulinus (Linnaeus, 1758) – breeds Denmark and S Sweden E in W Russia to R Ural, S to Iberia, France, lowland Italy and Sicily, Greece and Crete, W Turkey and foothills of NW Caucasus. *R. p. menzbieri* (Zarudny, 1913) – Turkey (except W), Armenia, Azerbaijan, NW Iran and Syria, possibly also extreme N Israel. *R. p. jaxarticus* (Severtsov, 1873) – E of Urals in W Siberia and N Kazakhstan E to NW foothills of Altai. *R. p. caspius* (Peltsam, 1870) – plains of SW Russia and NW Kazakhstan (R Volga–R Ural, W coastal lowlands of Caspian Sea and foothills of NE Caucasus).

Descriptive notes. 10–11 cm; 8–12.5 g. A small and relatively long-tailed passerine with conical pointed bill with straight culmen. Male nominate race has black mask extending over lores and ear-coverts and narrowly over base of bill, on forehead narrowly edged with chestnut above the black; crown and nape light grey, shading whiter above mask; mantle, back and upperwing-coverts chestnut, becoming lighter, more buffy, on rump, with uppertail-coverts dark brown; flight-feathers dusky, tertials widely edged light buff (forming pale panel); tail blackish, edged light buff; throat and chest whitish, shading to buffish on breast and dull

rufous-buff on flanks; side of breast often has a few chestnut spots (dark feather bases revealed as pale tips worn away); iris dark brown; bill dark grey, paler base and cutting edges; legs dark grey. Female is similar to male but coloration duller, crown and nape darker grey, mask less extensive over ear-coverts and narrower or absent over base of bill, mask also more grizzled with light buff; dark centres of wing feathers less contrasting. Juvenile is rather nondescript, has head and upperparts dull light greyish-buff, contrasting little with light buff of underparts, sometimes whiter throat and diffuse light eyering and supraloral stripe evident, as also are pale tertial fringes in fresh plumage; first-year male may have reduced mask, and can be difficult or impossible to distinguish from adult female. Races differ mainly in plumage tones, but complicated by individual variation and age differences: *menzbieri* is paler than nominate, with almost whitish rump, and lacks chestnut above base of bill; *caspius* male has most of forehead chestnut, sometimes also most of crown and nape (but usually some pale grey on upper nape), rump and uppertail-coverts very pale, latter almost whitish with dark shaft streaks, very pale fringes of wing feathers, more obvious spotting at side of breast, female usually has some rufous patches on crown and forehead, chestnut of upperparts usually restricted to lower mantle, whiter below than nominate; *jaxarticus* is a little smaller than nominate, has slender feet and smaller bill, also paler, with mantle cinnamon-rufous, rather than chestnut. **VOICE.** Usual call a thin, high-pitched and somewhat penetrating “seeoou”, not unlike sound made by unopened gate hinge, and resembling anxiety call of European Robin (*Erithacus rubecula*); varying in pitch and length according to whether bird in flight or foraging or tending nest. Song a variety of twittering phrases, interspersed with call note, and some snatches of mimicry of other bird species’ songs.

Habitat. Favours lakeside and riverine swampy vegetation, including that occurring at fish farms and tidal marshes. Prefers good mixture of emergent vegetation, including reeds (*Phragmites*), with reedmace (*Typha*), poplars (*Populus*) and willows (*Salix*); more locally also in coastal and estuarine tamarisks (*Tamarix*). Mainly lowlands; reported as nesting in poplars and orchards on hillsides in E Turkey and NW Iran, and in E Austria breeds at up to 650 m in some larger valleys.

Food and Feeding. Small invertebrates, chiefly larvae of small insects, also adult stages and their eggs; also seeds. Small spiders (Araneae) particularly important food items in reedbeds; in autumn and winter small seeds, e.g. of willow and reedmace are sought, and in late summer mealy plum aphid (*Hyalopterus pruni*) becomes abundant in reedbeds and then forms particularly important component of diet. Pecks in to hollow reed stems (which provide ideal hibernation sites for many small invertebrates). Forages in foliage of outermost branches of poplars and willows; visits flowers of willows in spring, perhaps for insects, but may also feed on nectar. Often holds willow catkin or tuft of reedmace seeds in its foot while it breaks into seeds; likewise, caterpillars are held down and decapitated before being swallowed. Usually in pairs or small family parties, but in winter and spring sometimes larger gatherings of up to 15 individuals; in late summer, juveniles may form loose groups of 20–30 individuals, with 60 an exceptional gathering. Rarely joins mixed-species parties.

Breeding. Season May–Jun in S Sweden, late Apr to early Jul in C Germany, May in Ukraine, Apr in S France, but not until late Jun in W Russia; reedbeds in E Austria (L Neusiedl) not sufficiently grown until mid-Jun, when birds of present species arrive to commence breeding (having perhaps

already reared a brood elsewhere); some pairs double-brooded. Mating system varies, can be monogamous, but often polygamous or polyandrous, and bond often severed by female after incubation begins. Nest-building takes 15–24 days to complete, but second or third nests constructed in 6–7 days; completed nest a globular pouch of felted plant fibres mixed with cobweb and some feathers, downward-pointing entrance tube at side, sometimes a second entrance tube incorporated, suspended at variable height (generally 3–4 m) from fork in outermost twigs of tree or bush, or between reed stems, often over water; construction started by male in attempt to attract female, female becomes involved when nest framework complete (“basket stage”); after mating, male often leaves completion of nest to female and begins another nest to attract another female, and so on; male may eventually incubate and rear one of these broods alone, as female equally promiscuous (may mate with up to six males in one season). Clutch 2–7 eggs (mean 5); incubation generally by female alone, period c. 13–14 days; chicks usually fed only by female, nestling period 18–26 days (mean 22 days); in some cases (usually with later clutches), male incubates eggs and rears young on his own; juveniles fed for a further 14 days before becoming independent.

Movements. N populations highly migratory; S ones less inclined to move very far. Most move S or SW to winter quarters, European birds wintering chiefly S & E Spain, S Portugal, W France and Italy, a few reaching Mediterranean coast of Morocco; some overwinter in E Austria (at L Neusiedl), vagrants occasionally in England, but more notable is significant winter population of up to 500 individuals in lagoons by Baltic coast of Latvia. Birds from S Russia, E Turkey and N Iran winter mainly from S Turkey and Iraq over S & E Iran E to Baluchistan (W Pakistan). Juveniles depart from breeding areas first, most leaving from mid-Jul onwards, including random dispersal to N as well as to S & W; adults tend to move out in first half of Aug, with passage through Germany from late Sept to Nov. Surprisingly large numbers have been recorded as flying S through Israel, indicating an as yet unknown wintering area, possibly at the Nile Delta (although very few records for Egypt). Spring passage can begin as early as Feb, with peak passage through C Europe (e.g. Switzerland) first week Apr but movement continuing until mid-May.

Status and Conservation. Not globally threatened. Patchily not uncommon over most of range, but distinctly localized and forming small “colonies” along riversides. Population sizes difficult to assess because of the species’ unusual mating behaviour; breeding numbers cannot be given as pairs, but density can be expressed in terms of nests, highest densities of which range are 9.4–13.8/10 km², or of simultaneously reproductive females, with 4.8–7.8/10 km². Nevertheless, most summaries refer to “pairs”, with basic summaries of up to 200 pairs in France, at least ten in Belgium, five in Luxembourg, 250 in Netherlands, well over 5000 in Germany, 150 in Denmark, up to 100 in Sweden, up to 300 in Latvia, 10,000 in Poland, 5000 in Czech Republic, up to 10,000 in Slovakia, 3000 in Hungary, about five in Switzerland, up to 14,600 in Spain, up to 30,000 in Italy, 3000 in Greece, 2000 in Albania, up to 10,000 in Croatia, 300 in Slovenia, up to 10,000 in Bulgaria, 8000 in Romania, up to 100,000 in European Russia, 12,000 in Ukraine, 1000 in Moldova, 800 in Belarus and up to 500,000 in Turkey. Breeding sporadic in Portugal, Iraq and Syria; exceptionally, has bred in England. Present in Spain since 1950s; in S France had disappeared from Camargue by early 1980s but has become more frequent W of Rhone delta, and now breeding also in N France. Since 1950s, this species has undergone considerable range expansion to W in a series of waves across Europe, but cannot be considered common anywhere; reached C Poland, Denmark, Slovakia, E Germany and E Austria by 1965, then S Sweden and C Germany by 1975, and S Finland, N Netherlands and NE France by 1985. Changes in habitat and riverbank management, the creation of fish farms and gravel pits, and creation of lakes through mining subsidence, as well as open-cast mining, have helped to provide additional and better habitats, of which the species has taken full advantage. Further, eutrophication of lakes and slow-flowing rivers has permitted the growth of many plants which provide materials suitable for nest construction, i.e. hop (*Humulus*) and nettles (*Urtica*).

2. Black-headed Penduline-tit

Remiz macronyx

French: Rémiz à tête noire **Spanish:** Pájaro-moscón Cabecinegro
German: Schwarzkopf-Beutelmeise

Taxonomy. *Aegithalus* [sic] *macronyx* Severtsov, 1873, Shymkent (Chimkent), Syr Darya, south Kazakhstan.

Forms a species group with *R. pendulinus*, *R. coronatus* and *R. consobrinus*, and all four often combined as one species; sometimes present species considered conspecific with first of those, and the other two united as a separate species. Treatment as four distinct species based mainly on structural, as well as plumage and habitat, differences. Present species frequently hybridizes with *R. pendulinus* by N & SW shores of Caspian Sea; hybrids in N (mouth of R Ural) named as *bostanjogli*, and those in S as, respectively, *loudoni* and *altaicus*; last-mentioned sometimes treated as a valid race. Moreover, *ssaposhnikowi* believed probably to have originated as hybrid between nominate race of present species and race *jaxarticus* of *R. pendulinus*, although neither parent found within current range of *ssaposhnikowi*. Race *neglectus* sometimes synonymized with nominate. Birds from Aral Sea region described as race *aralensis*, but considered inseparable from nominate. Four subspecies currently recognized.

Subspecies and Distribution.

R. m. neglectus (Zarudny, 1908) – N Iran and SW Turkmenistan.
R. m. macronyx (Severtsov, 1873) – SW Kazakhstan, Uzbekistan, N & SE Turkmenistan, Tajikistan, and probably NE Afghanistan.
R. m. ssaposhnikowi (H. E. Johansen, 1907) – SE Kazakhstan (L Balkhash, L Sasykkol and L Alakol).
R. m. nigricans (Zarudny, 1908) – SE Iran (Sistan) and probably SW Afghanistan.

Descriptive notes. 10–11 cm; c. 9.3–10.5 g. A small, dark-hooded, buffy penduline-tit; strong legs with large hind claw. Male nominate race has entire head to throat and upper breast sooty black or

On following pages: 3. White-crowned Penduline-tit (*Remiz coronatus*); 4. Chinese Penduline-tit (*Remiz consobrinus*); 5. Sennar Penduline-tit (*Anthoscopus punctifrons*); 6. Yellow Penduline-tit (*Anthoscopus parvulus*); 7. Mouse-coloured Penduline-tit (*Anthoscopus musculus*); 8. Grey Penduline-tit (*Anthoscopus caroli*); 9. Cape Penduline-tit (*Anthoscopus minutus*); 10. Forest Penduline-tit (*Anthoscopus flavifrons*); 11. Verdin (*Auriparus flaviceps*); 12. Fire-capped Tit (*Cephalopyrus flammiceps*); 13. Tit-hylia (*Pholidornis rushiae*).

warm dark brown (feathers finely tipped pale buff when fresh), narrow pale buff collar bordering upper mantle (adding to hooded effect); mantle and upper scapulars chestnut, feathers fringed cinnamon, lower scapulars and back to uppertail-coverts pale cinnamon, becoming almost whitish on uppertail-coverts, which have dark shaft streaks; upperside feathers reddish-brown or blackish, fringed pale cinnamon in fresh plumage; tail blackish, edged off-white; sides of breast chestnut, each feather fringed pale buff, remainder of underparts light buff with dark feather bases (which may be visible to varying extent as pale tips

abrade); iris dark brown; bill dark grey, paler base and cutting edges; legs dark grey. Differs from congeners mainly in absence of grey or white areas on head and nape. Female is similar to male but less well marked, has buff feather tips more extensive, so throat less dusky when plumage fresh. Juvenile is rather nondescript, head and upperparts dull greyish, contrasting little with light buff of underparts; seemingly indistinguishable from juvenile of *R. coronatus*. Races differ mainly in plumage tone and pattern, but confused by individual variation through age, sex and plumage wear: *neglectus* is similar to nominate but smaller; *nigricans* is darkest, dark colour of hood extending over mantle and most of underparts, becoming even darker when plumage worn (most of dark feather bases of underparts then revealed); *ssaposhnikovi* is variable, darker individuals close to nominate, paler ones with some chestnut and whitish on crown and nape and whitish throat (latter easily confused with both *R. coronatus* and hybrids between *R. pendulinus* and present species from Caspian region). VOICE. Poorly documented; calls said to have louder and coarser tone than those of *R. pendulinus*, and male said to give brief, quiet trill in spring.

Habitat. Low-lying lakesides and riverbanks with stands of reeds (*Phragmites*) and reedmace (*Typha*); avoids dense reedbeds.

Food and Feeding. Small invertebrates, chiefly larvae of small insects, also adult stages and their eggs, also small spiders (Araneae); seeds of aquatic plants, particularly Compositae, also taken. Spends most of foraging time in reeds, avoiding trees. Few other details on behaviour; presumed to be much as that of *R. pendulinus*, but flight action said to be slower.

Breeding. Breeds from late May to mid-Jun, following spring rains, and many recently fledged juveniles by mid-Jul. No information on mating system, but perhaps equally as complex as those of *R. pendulinus*. Nest an elongated globular pouch, downward-pointing entrance tube at side, made from felted plant down, feathers and cobwebs along with reed flowerheads, reed leaves stripped into narrower pieces and woven into base, typically built between two reed stems, these usually "tied" together with plaited strips of plant fibres below nest for extra support in windy conditions; often placed as low as 30–120 cm above water level, but if built in tree can be as high as 3 m. Clutch 6–7 eggs; incubated probably by female alone, but little information available; no information on duration of incubation or on nesting period.

Movements. Primarily resident. Some remain all year as far N as S Kazakhstan; likely, however, that at least some of N & E populations move W or SW to winter in Caspian lowlands of N Iran. As large numbers of *R. pendulinus* of Caspian race (*caspius*) spend non-breeding season in Israel, possible that some individuals of present species could occur with them, perhaps also in S Iran and Iraq; sight record of "a black-headed" penduline-tit in N Oman (Muscat, at entrance to Persian Gulf) on 29th Mar 1971 could refer to this species. Passage through Turkmenistan reported from late Feb into early Mar, and through Tashkent (Uzbekistan) from mid-Mar to early Apr; autumn passage from late Sept until start of winter.

Status and Conservation. Not assessed. Common to fairly common in most of range; rare, possibly extinct, in SE Iran. Common along S shores of Caspian Sea in N Iran and in adjacent S Turkmenistan; has been reported even as locally abundant in N Iran, where nests spaced at c. 250 m in prime habitats. Changes in agriculture in C Asia have been dramatic, and Aral Sea virtually lost through massive irrigation schemes; effects on populations of this species probably equally dramatic, but little information available. In S of range, in Sistan depression (in SE Iran), distinctive dark race *nigricans* has not been seen for many years, and possibly extinct; perhaps survives in adjacent SW Afghanistan, where massive lake Hamun-i-Puzak (a Ramsar site) holds permanent water and formerly had extensive reedbeds, but periodic droughts, combined with reed-cutting by local villagers, must have had negative impact; most serious threat in SW Afghanistan is proposal to build a paper factory (using reeds as raw materials) in nearby Helmand Province, but whether or not this will become a reality remains to be seen.

Bibliography. Cramp & Perrins (1993), Dementiev *et al.* (1954a, 1970), Dolgushin *et al.* (1972), Evans (1994), Gallagher & Woodcock (1980), Gavrilov & Zhatkanbaev (1995), Harrap & Quinn (1996), Hartert (1907a), Ivanov (1940), McCarthy (2006), Shirihai (1996), Stepanyan (1990, 2003), Vaurie (1950a, 1952, 1957a, 1959).

3. White-crowned Penduline-tit

Remiz coronatus

French: Rémiz couronnée **German:** Kronenbeutelmeise **Spanish:** Pájaro-moscón Coronado
Other common names: Crowned/Black-headed(?) Penduline-tit

Taxonomy. *Aegithalus* [sic] *coronatus* Severtsov, 1873, Nau, near Khodzhen, Tajikistan.

Forms a species group with *R. pendulinus*, *R. macronyx* and *R. consobrinus*, and all four often combined as one species; probably most closely related to *R. pendulinus*, but sometimes considered conspecific with *R. consobrinus* (the other two then united as a separate species). Treatment as four distinct species based mainly on structural, as well as plumage and habitat, differences; present species differs from others in genus in bill and leg structure, as well as habitat preferences. Races intergrade in SE Kazakhstan. Proposed races *centralasiae* (from C Asia) and *yeniseensis* (from Sayan and Tannu-ola, on upper course of R Yenisey, in S Russia) both considered inseparable from *stoliczkae*. Two subspecies recognized.

Subspecies and Distribution.

R. c. coronatus (Severtsov, 1873) – breeds S & SE Kazakhstan, N Uzbekistan, S Turkmenistan and Amu Darya valley, Kyrgyzstan, NW China (Ili valley, in NW Xinjiang), Tajikistan and NE (probably also NW) Afghanistan; non-breeding E Iran, N & W Afghanistan, Pakistan and NW India (E to Haryana).

R. c. stoliczkae (Hume, 1874) – breeds E Kazakhstan, S Russia (from Altai E to Chita, in S Transbaikalia), NW & C Mongolia and NW & N China (Xinjiang E, excluding Ili valley, to Ürümqi; N Ningxia).

Descriptive notes. 10–11 cm; 9.3–10.5 g. A clearly patterned penduline-tit with small, narrowly conical bill and relatively slender legs and toes. Male nominate race has black mask over lores and ear-coverts extending narrowly over base of bill, and more obviously across upper nape; crown

very light grey, shading whiter above mask, crown appearing almost white in the field (blackish feather bases always concealed by wide whitish tips on forecrown, but often abrading to show dusky markings over rear crown); nape, side of neck and uppermost mantle whitish (giving effect of wide white collar), lower mantle and scapulars chestnut, latter widely tipped cinnamon, back to uppertail-coverts dull cinnamon-buff, each feather narrowly fringed paler (slightly mottled appearance); upperside-coverts dark grey, tipped cinnamon, primary coverts blackish, tertials, secondaries and primaries dark grey,

widely edged buffy white; tail blackish, edged whitish, particularly on outermost feather; throat, breast and fore flanks off-white (with wear, chestnut bases of breast feathers revealed as random spotting), remainder of underparts buffy white; iris dark red or dark brown; bill dark grey, paler base and cutting edges; legs dark grey. Distinguished from superficially similar *R. pendulinus* mainly by more clearly contrasting plumage pattern, no chestnut on crown, broad black mask extending across upper nape and highlighting almost white collar on lower nape, also by particularly small and fine bill and more slender legs and toes. Female is similar to male but duller, with crown and nape greyer, mask browner and less extensive (usually not extending over base of bill and diffusing on upper nape), rump and uppertail-coverts also greyer, less buffish. Juvenile is rather nondescript, having head, side of breast and upperparts dull grey, becoming washed with cinnamon-buff on rump and scapulars, wing as adult but duller, underparts uniform light buff; first-year male may have reduced mask and be difficult or impossible to distinguish from adult female, but has mantle and scapulars richer chestnut. Race *stoliczkae* has even smaller bill than nominate, upperparts paler and buffier, less chestnut or rufous, and mask more dusky and diffuse, especially on upper nape (where incomplete). VOICE. Usual call a thin and high-pitched "seeoo", very much like that of *R. pendulinus* but perhaps a little shorter and fuller, less fading; other calls include "ti-ti-ti-ti-ti", given also in flight, and various single notes e.g. "sweet" or "tsi", all high-pitched and plaintive.

Habitat. Breeds in stands of poplars (*Populus*) and willows (*Salix*) by lowland rivers and in meadows of floodplains, locally also on bushy hillsides, and in gardens, orchards and walnut (*Juglans*) groves; in Kyzylkum Desert (Uzbekistan) nests in turanga trees (*Populus euphratica*) in the saxaul (*Haloxylon*) scrub; breeds as high as 2400 m in W Tien Shan. In non-breeding season found in equally varied selection of habitats, notably open forest, tamarisks (*Tamarix*), tree-lined embankments, reservoirs, and sometimes reedbeds (shunned in breeding season, but popular in winter in Pakistan). In limited area of range overlap with *R. pendulinus*, present species prefers bushy slopes, rather than reedbeds.

Food and Feeding. Small invertebrates, chiefly small insects and their larvae, and small spiders (Araneae); also seeds. Large number of seeds, especially those of reedmace (*Typha*), taken in winter months; in Mongolia, willow seeds form important component of diet through breeding season. Forages nearly always in poplars and willows, in general avoiding reedbeds; in Pakistan, passage migrants in spring tend to forage in canopy of trees. Forms small flocks outside breeding season, with reports of up to 50 individuals together in autumn and 40 on spring passage.

Breeding. Breeds from late May to mid-Jun in C Asia and in Jun in Mongolia and extreme NE of range (Buryatia, in Russia); fledged young in first week Jul. No information on mating systems, but perhaps monogamous. Nest built by both sexes, but female settles down to incubate as soon as bowl complete, while male continues to build remainder of nest; an elongated globular pouch, downward-pointing entrance tube at side, typically of woven plant fibres and down from willows and poplars, suspended c. 6–8 m above ground from near tip of horizontal branch of tree. Clutch 3–9 eggs; incubation by female, fed on nest by male; no information on duration of incubation and fledging periods; fledged juveniles gather into small flocks.

Movements. Strongly migratory. Arrives on breeding grounds in Mongolia in late May to early Jun, departing again in Sept and Oct; timing similar in S Siberia and Kazakhstan. In mild winters a few remain in lower-lying parts of Uzbekistan and Tajikistan. Passes through SW Turkmenistan en route to non-breeding grounds in E Iran and SW Afghanistan, where present Nov–Feb; small parties recorded in NW China (Xinjiang) in Mar probably also on passage (although initially suggestive of breeding). Wintering birds arrive in Pakistan as early as late Sept in some years, but normally majority arrive in Dec, remaining until end of Mar; on spring passage noted mid-Mar to mid-Apr farther N in Pakistan. A few penetrate into borderlands of NW India. Non-breeding quarters of race *stoliczkae* (breeding in NE of range) unknown. A remarkable case of vagrancy involved an individual trapped on 1st Aug 1987 at L Neusiedl, in E Austria.

Status and Conservation. Not globally threatened. Locally fairly common to uncommon. Not considered common anywhere in range, and is particularly uncommon over extreme N parts of distribution in Siberia; no longer occurs in Minusinsk Depression (SC Siberia), having been lost as a result of intensified economic development. In E Kazakhstan, however, appears to be relatively numerous, with density of 1 nest/100 m² in prime habitats. In Iran and Afghanistan it is an uncommon and localized winter visitor (main wintering areas are riverine plains of Pakistan). Status in China requires clarification. Possibly breeds also in NE Iran; alleged breeding in India based on a specimen said to have come from Ladakh (NW India) in Jun, but this considered dubious.

Bibliography. Cramp & Perrins (1993), Dementiev *et al.* (1954a, 1970), Dolgushin *et al.* (1972), Gavrilov & Zhatkanbaev (1995), Harrap & Quinn (1996), Ivanov (1940), Jones (1931), Kozlova (1930), McCarthy (2006), Rasmussen & Anderton (2005b), Roberts (1992), Rogacheva (1992), Stepanyan (1990), Vaurie (1950a, 1952, 1957a, 1959).

4. Chinese Penduline-tit

Remiz consobrinus

French: Rémiz de Chine **German:** Chinabeutelmeise **Spanish:** Pájaro-moscón Chino

Taxonomy. *Aegithalus* [sic] *consobrinus* Swinhoe, 1870, Sha-she (= Shasi), below Ichang, Hubei, China.

Forms a species group with *R. pendulinus*, *R. macronyx* and *R. coronatus*, and all four often combined as one species; probably most closely related to *R. pendulinus*, but sometimes considered conspecific with *R. coronatus* (and the other two then united as a separate species). Treatment as four distinct species based mainly on structural, as well as plumage and habitat, differences. Monotypic.

Distribution. Breeds locally in Russian Far East and in NE China (in E Nei Mongol and adjacent Heilongjiang, NW Jilin, S Ningxia, possibly also S Liaoning); non-breeding mainly E & S China

(middle and lower Yangtze valley, also Yunnan and Hong Kong), S Korea and S Japan (chiefly Kyushu and Honshu).

Descriptive notes. 10.5 cm; 7.5–11.9 g. A typical penduline-tit, clearly patterned and with rather long and narrowly conical bill. Male has black mask extending over lores and ear-coverts and narrowly over base of bill; crown, nape and side of neck grey, feathers tipped dull cinnamon in fresh plumage (making nape appear buffy grey), border of mask, including forehead, rear ear-coverts and submoustachial area, whitish; upper mantle chestnut, feathers tipped cinnamon, becoming cinnamon on lower mantle and scapulars, latter with dark feather bases (may become visible with wear), back to uppertail-coverts dull cinnamon-buff, each

feather narrowly fringed paler (slightly mottled appearance); upperwing dark grey, all feathers tipped or fringed with cinnamon or buff; tail blackish, all feathers widely edged buff; chin, throat and breast light buff, contrasting with white of submoustachial area, and with chestnut mottling against rufous-buff background at side of breast, latter meeting rusty colour of upper mantle (forming a collar); remaining underparts buff, washed cinnamon on flanks; iris dark brown; bill dark grey, paler base; legs dark grey. Differs from somewhat similar *R. coronatus* mainly in having less extensive black mask surrounded by (and highlighted by) white border, with greyer crown and nape, no blackish on upper nape (lacks whitish-collared appearance), buffy colour below extending to chin and throat and highlighting white submoustachial area. Female is much duller than male, with crown, nape and mantle light buffy brown, mask dark brown or reddish-brown, weakly mottled buff, and with dull off-whitish surround; back, rump and uppertail-coverts as male, wings buffy grey, all feathers tipped or fringed paler, tail blackish, all feathers widely edged buff; throat and underparts warm buff, in worn plumage sometimes some rusty spotting at side of breast and on mantle. Juvenile is not well known, rather nondescript, being more or less uniform dull brownish-buff; first-year male as female, but mask blacker and upper mantle distinctly chestnut. **VOICE.** Use call a thin and high-pitched “tsee” or “psee”, very similar to call of *R. pendulinus*; other calls also similar to latter’s, including fuller “piu” and a “siu, siu, siu, siu” series. Song a repetition of “si, si, tiu, si, si, tiu”, given in see-sawing rhythm like that of a parid tit.

Habitat. Variety of wetland habitats, particularly with reedbeds fringed by bushes and trees, especially poplars (*Populus*) and willows (*Salix*) for nest materials; found both by freshwater marshes and lakes and by tidal saltmarshes. More unusual away from water in poplar plantations and orchards. Outside breeding season can be encountered in wider range of habitats, including weedy rank vegetation in coastal districts.

Food and Feeding. Small invertebrates, chiefly small insects and their larvae, and small spiders (Araneae); also, in winter months, large amount of seeds taken. Spends much time in reedbeds, investigating panicles of reed-heads; foraging behaviour seems to be much as that of *R. pendulinus*. Forms small to quite large flocks outside breeding season, particularly at passage times and in winter.

Breeding. Not well studied. Probably breeds from late May to mid-Jun in China. No information on mating systems, but perhaps monogamous. Nest typically an oval pouch, entrance tube near top, made from woven plant fibres and down from willows and poplars, suspended from near tip of reeds, or in bush, once 4 m above ground in poplar tree several hundred metres from water at edge of a plantation. Clutch 5–10 eggs. No other information.

Movements. Strongly migratory. Present on breeding grounds in NW Jilin from mid-Apr until late Sept, and in S Liaoning (where possibly breeds) from late Apr. Seems to migrate on narrow front through NE China, with main wintering areas along middle and lower reaches of R Yangtze and in W Yunnan (along R Nu Jiang), and small but increasing numbers wintering in Hong Kong (at Mai Po Marshes) from Nov to mid-Apr and occasionally into May; locally not uncommon winter visitor in Japan (Kyushu and Honshu) since 1970s, and in nearby S Korea small numbers from Oct to May. Fairly common on spring migration through N Korea in Apr and May. Vagrant recorded in C Ryukyu Is (Okinawa) in Mar 1987.

Status and Conservation. Not globally threatened. Poorly known. Breeds very locally in NE China, and recently discovered to be breeding in Russian Far East. Although extent of breeding grounds not well known, observations outside breeding season have increased massively since c. 1980s, indicating that this species is not at any immediate risk. Migration studies reveal population explosion on scale similar to that demonstrated by *R. pendulinus* in W Eurasia; for example, at Beidaihe, in coastal Hebei (China), only a handful of individuals passing in 1920s and 1940s, compared with maximum day count of 2715 moving S in 1988 (on 11th Oct). In Japan, considered a winter vagrant until 1970s, now an uncommon to locally common winter visitor, sometimes in large flocks, to Kyushu and W Honshu. Much farther S, in Hong Kong, first recorded in Apr 1980, thereafter small waves of migrants, with maximum day count of 250 passing over in 1991 (24th Nov). Origins of all of these migrants a mystery, but this penduline-tit is evidently a successful species.

Bibliography. Brazil (1991), Burkovskiy (1997), Chen Youling & Tang Zhaohe (1998), Cheng Tsohsin (1987), Cramp & Perrins (1993), Harrap & Quinn (1996), MacKinnon & Philipps (2000), Melville & Galsworthy (1991), Song Yujun *et al.* (1984), Tong Junchang *et al.* (1985), Turnbull *et al.* (2007), Vaurie (1950a, 1952, 1957a, 1959), Wilder & Hubbard (1938), Williams *et al.* (1992), Zhang Lixun *et al.* (2006), Zhao Zhengjie *et al.* (1984).

Genus *ANTHOSCOPUS* Cabanis, 1851

5. Sennar Penduline-tit

Anthoscopus punctifrons

French: Rémiz du Soudan **German:** Sudanbeutelmeise **Spanish:** Pájaro-moscón Sudanés
Other common names: Sudan Penduline-tit, Kapok/Cappoc Tit

Taxonomy. *Aegithalus* [sic] *punctifrons* Sundevall, 1850, Sennar, east Sudan.

Forms a superspecies with *A. parvulus*, *A. musculus*, *A. caroli* and *A. minutus*. Monotypic.

Distribution. Extreme S Mauritania and NE Senegal E in Sahel zone to S Mali and N Burkina, S Niger, extreme NE Nigeria, C Chad, extreme N Cameroon, C & EC Sudan and W Eritrea.

Descriptive notes. 7.5–8.5 cm; c. 6–8 g. Tiny unmarked olive-and-whitish passerine with small, conical, sharply pointed bill; legs quite strong, tibia short. Forehead and forecrown are yellow,

or blackish-brown; bill blackish, becoming paler towards base and on cutting edges; legs slate-grey or blue-grey. Differs from *A. musculus* mainly in having green tones in plumage, much stronger spotting on forehead; from *A. parvulus* in duller general appearance, lacking obvious bright yellow. Sexes similar. Juvenile is duller than adult, more greyish (less olive) in tone above, but usually with hint of yellowish on forehead. **VOICE.** Variety of thin, high-pitched notes, e.g. “seewi-seewi-seewi...” or more buzzy “dzzeewi-dzzeewi-dzzeewi...”, repeated 6–9 times, often accompanied by a prolonged rattle from a second individual; abrupt “tsit” also reported, as well as a churring “whut-chrrrrrrrr” and harsh “tchuwhee-whree”.

Habitat. Semi-desert or desert-steppe with scattered scrub and larger trees and bushes in wadis; favours presence of water, hence especially fond of larger trees near bore holes, wells, etc. In Eritrea, at least, usually found below 1075 m.

Food and Feeding. No information on diet; birds foraging in acacia (*Acacia*) canopy appeared to be searching for insects. Forages actively, usually in parties of three individuals, keeping in contact with constant calling. Basic behaviour seems to differ little from that of congeners.

Breeding. Very little known. Breeding season Jun–Sept in Mauritania, Jun–Aug in Senegal, Jul–Aug in Mali, Jul in Nigeria, Jul–Sept in Chad, Feb–Mar and Sept in Sudan, and possibly May in Eritrea. Several nests found, but none well documented; nest described as being very similar to that of *Remiz pendulinus* and rather large for such a small bird. Nest in Chad on 23rd Sept held two juveniles almost ready to fledge. No other information.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Locally common. Despite scant knowledge of its breeding habits, this species seems to be locally numerous, although evidently shunning large expanses of suitable habitat. Abundant along R Senegal and a little to N in S Mauritania and N Senegal, and widespread and locally abundant in wooded country by water-holes and lakes in S Mali. No recent records from Niger; in Nigeria known only from extreme NE in vicinity of L Chad, and similarly in Cameroon recorded only in L Chad area and in Waza National Park, both in extreme N. In Chad quite common in the Sahel and soudanian savannas across centre of country, and in Sudan widely reported across Darfur and along Blue Nile and White Nile; no records from Ethiopia, but in Eritrea an uncommon and little-known species in W of the country.

Bibliography. Borrow & Demey (2001), Fry *et al.* (2000), Hall & Moreau (1970), Harrap & Quinn (1996), Mackworth-Præd & Grant (1973).

6. Yellow Penduline-tit

Anthoscopus parvulus

French: Rémiz à ventre jaune **German:** Senegalbeutelmeise **Spanish:** Pájaro-moscón Amarillo
Other common names: West African/Least Penduline Tit

Taxonomy. *Aegithalus* [sic] ? *parvulus* Heuglin, 1864, Bongo, Bahr-el-Ghazal, south Sudan.

Forms a superspecies with *A. punctifrons*, *A. musculus*, *A. caroli* and *A. minutus*. Geographical variation sometimes considered to be clinal, and complicated by effects of plumage wear; species treated by some authorities as monotypic. Proposed race *citrimus* (described from Bozoum, near Bouar, in W Central African Republic) considered inseparable from *senegalensis*. Three subspecies provisionally recognized.

Subspecies and Distribution.

A. p. senegalensis (Grote, 1924) – extreme S Mauritania, Senegal, Gambia and Guinea Bissau E to N Benin, N Nigeria (E to W & S areas of L Chad), N Cameroon (Bénoué National Park) and W Central African Republic.

A. p. aureus Bannerman, 1939 – NW Ghana (Bole).

A. p. parvulus (Heuglin, 1864) – S Chad (S & E from E shores of L Chad), S Sudan and N DR Congo, possibly also extreme NW Uganda.

Descriptive notes. 8 cm; c. 6–8 g. Tiny unmarked olive-yellow passerine, the brightest member of the genus, with small, sharply pointed conical bill and quite strong legs and feet, with short tibia. Nominate race has forehead and forecrown bright yellow, freckled with dusky, relatively weak yellowish supercilium merging with yellow forehead; dull greyish stripe through eye, darker and more conspicuous on lores; crown and upperparts, including side of neck, yellowish olive-green, tinged greyish, becoming yellower on rump and uppertail-coverts; upperwing blackish-brown, feathers edged yellow-green, primaries

edged buffish-white (forming narrow whitish panel in fresh plumage); tail blackish-brown with yellow-green feather edges; chin to undertail-coverts rich yellow with very faint olive wash; with plumage wear, wing and tail become bleached brown (feather fringes abraded) and underparts become dingier yellow; iris brown or blackish; bill blackish, becoming paler towards base and on cutting edges; legs slate-grey or blue-grey. Distinguished from congeners mainly by much brighter, more extensively yellow coloration. Sexes alike. Juvenile is duller than adult, and paler yellow on forecrown and underparts. Races differ mainly in intensity of yellow in plumage: *senegalensis* is brighter than nominate, more yellow-looking, lacks greyish tinge above, yellow of forehead contrasting less with yellower crown; *aureus* is dull, with duller yellow forecrown and somewhat duller underparts, but in fresh plumage has stronger whitish wingpanel. **VOICE.** Contact calls a thin “si, shi-shi”, said to be vaguely reminiscent of calls of Northern Long-tailed Tit (*Aegithalos caudatus*). Song a tuneless, rapid, urgently repeated “ska-ska-ska-ska...” or double-noted “pichee” in bursts of 6–12 notes for 1–2 seconds.

Habitat. Dry or semi-arid sandy or short-grass savanna of soudanian type, in places extending S into guinean zone and N into more arid Sahel. Favours large shady trees growing by watercourses, or stands of large acacias (*Acacia*); also, very locally (Zaria, in N Nigeria), in bushy scrub and light woodland plantations grown for fuel. Can be found even in quite degraded and overgrazed savanna.

Food and Feeding. Known food items are small insects and their larvae. Forages chiefly in upper canopy; flits with buoyant flight from tree to tree, when relatively bright yellow coloration renders it conspicuous. Forages in parties of 3–6 individuals, or often in pairs; small flocks of up to 30 individuals sometimes encountered. Readily associates with mixed feeding flocks of other small birds, particularly white-eyes (*Zosterops*) and eremomelas (*Eremomela*).

Breeding. Poorly known. Birds in breeding condition in Mar in Gambia, Feb–Mar in Mali (Bamako), Jan in Ghana and Jun in Nigeria (Argungu). Only one nest described, a hanging pouch of beautifully woven, extremely strong felted materials, with self-closing short tubular entrance (bird using foot to open this), attached to twig c. 5–5 m above ground near very top of soft-leaved tree. Clutch 2 eggs. No further information.

Movements. Chiefly sedentary, but some seasonal movements in at least some parts of range. In S Mauritania considered to be only a wet-season visitor, and likewise in Gambia seems to be only a wet-season visitor to coastal forests from upriver; in Ghana, apparently disappears from Mole National Park by height of dry season, whereas it is common there from May to Sept (during wet season). In contrast, no such seasonal fluctuations reported from Nigeria.

Status and Conservation. Not globally threatened. Surprisingly poorly known, and generally considered to be uncommon or scarce over much of range. Recorded at a wide scatter of sites in Senegal and adjacent Gambia, Guinea-Bissau and extreme S Mauritania; has been described as locally common in parts of Mali, and this appears to be the case right across soudanian zone to S Sudan, although records sparse and gaps in known range large over much of E portion of range. Occurs in a number of protected areas, including Mole National Park, in Ghana, Arli-Pendjari National Park, in Burkina, and Kainji Lake National Park, in Nigeria; also in Bènoué National Park, the only confirmed locality for Cameroon. The future for this species, however, seems reasonably secure: unlike many specialized small bird species, it appears to tolerate habitat degradation caused by chopping for firewood and overgrazing by domestic animals, particularly goats.

Bibliography. Bannerman (1948), Borrow & Demey (2001), Fry *et al.* (2000), Hall & Moreau (1970), Harrap & Quinn (1996), Jensen & Kirkeby (1980), Mackworth-Præd & Grant (1973), Serle (1943b).

7. Mouse-coloured Penduline-tit

Anthoscopus musculus

French: Rémiz souris **German:** Graubeutelmeise **Spanish:** Pájaro-moscón Gris
Other common names: Mouse-coloured Tit

Taxonomy. *Aegithalus* [sic] *musculus* Hartlaub, 1882, Lado, Upper Nile, south Sudan.

Forms a superspecies with *A. punctifrons*, *A. parvulus*, *A. caroli* and *A. minutus*. Birds from Kenya have been separated as a geographical race (*guasso*) on basis of rather greyer plumage compared with birds from farther N, but age-related feather wear could be responsible for such apparent differences. Monotypic.

Distribution. SE Sudan (E from Lado and Tombe), Ethiopia, NW, N & S Somalia, NE Uganda, Kenya and extreme NE Tanzania.

Descriptive notes. 8 cm; c. 6–8 g. Tiny unmarked dull grey-brown passerine with whitish underside, very short tail, short, pointed conical bill, and quite strong legs and feet with short tibia. Has most of head and upperparts dull brownish-grey; forehead and ear-coverts indistinctly washed light buff, weakly freckled darker, in the field head appearing relatively plain but with dusky loreal line, bordered above by indistinct pale supraloral line; wing and tail feathers darker, with lighter greyish fringes; chin, throat and underparts off-white, lightly washed buff on belly and undertail-coverts; iris brown; bill blackish, becoming paler

towards base and on cutting edges; legs dark blue-grey or blackish. Distinguished from *A. caroli* mainly by entirely whitish underparts. Sexes similar. Juvenile (in fresh plumage) is slightly warmer brown, less greyish-tinged, on upperparts than is adult. **Voice.** Typical contact call a high-pitched “tit, tit, tit...”; also gives abrupt, nasal “tzeee” or “bzeu”. Song consists of several repeated phrases, including rapid rattled “di-di-di-di-di...”, ringing “we-cha-we-cha-we-cha-we-cha...” and thin “tsee-tsi, tsee-tsi, tsee-tsi...”.

Habitat. Open acacia (*Acacia*) woodland, dry bush and short-grass savanna in arid or semi-arid country. Recorded between 400 m and 1600 m in plains and mountain foothills.

Food and Feeding. No specific details on diet, but assumed to be primarily small insects and their larvae. Forages in pairs or in family parties, often associating loosely with groups of other small bird species. Feeds low down in scrubby bushes, as well as in canopy of large acacias. Very active, constantly on the move, one moment swinging upside-down in typical remizid fashion, the next stretching as if on “tip-toe” to reach food item. Can be quite confiding during foraging, seemingly unworried by human presence.

Breeding. Nesting reported in Dec in Sudan, Feb–Mar and Sep–Oct in Ethiopia, Nov in Somalia and Apr–May in Kenya. Nest a pear-shaped pouch of felted soft plant fibres virtually identical to that of *A. caroli*, intensely worn to produce false chamber (which a predator enters via false entrance hole), true entrance concealed by flap, which parent secures when leaving; few nests found, one was quite exposed, situated 2 m above ground in thorn bush, others reported as sited 1–5–6 m above ground in acacia. Clutch 4 eggs; so far as is known, incubation primarily, perhaps wholly, by female. No further information.

Movements. None documented; presumably disperses during conditions of extreme drought.

Status and Conservation. Not globally threatened. Not uncommon; easily overlooked owing to tiny size and inhospitable habitat. Recently found to be not uncommon at several sites in Ethiopia and Kenya; only sporadic reports in N & NW Somalia and adjacent E Ethiopia. In Sudan common in extreme S, between Bor and the foothills of Dongotona Mts; one exceptional record from Kassala region of NE Sudan. In Somalia scattered records from throughout interior, but breeding reported only in S. Occurs in several protected areas, including e.g. Awash National Park, in Ethiopia, Kidepo Valley National Park, in Uganda, Marsabit, Meru, Samburu and both Tsavo East and Tsavo West National Parks, in Kenya, and Arusha National Park and Mkomazi Game Reserve, in Tanzania. Greatest threat to the species is habitat degradation through overgrazing by goats and the lopping of acacias for fuel.

Bibliography. Archer & Godman (1961), Ash & Miskell (1998), Austin (1978b), Benson (1946), Britton (1980), Fry *et al.* (2000), Hall & Moreau (1970), Harrap & Quinn (1996), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1960), Zimmerman *et al.* (1996).

8. Grey Penduline-tit

Anthoscopus caroli

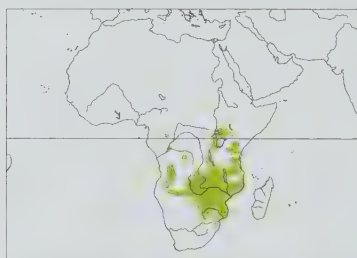

French: Rémiz de Carl **German:** Weißstirn-Beutelmeise **Spanish:** Pájaro-moscón Africano
Other common names: African Penduline-tit; Rungwe/Buff-bellied Penduline-tit (*sylviella* and *sharpei*); Zambesi Penduline-tit (*rankinei*)

Taxonomy. *Aegithalus* [sic] *caroli* Sharpe, 1871, Ovaquenyama, Damaraland, Namibia.

Forms a superspecies with *A. punctifrons*, *A. parvulus*, *A. musculus* and *A. minutus*. Races can be divided into five groups, “nominate group” (incorporating also *hellmayri*, *robertsi* and *winterbottomi*), “ansorgei group” (with *rhodesiae* and *pallascens*), “*sylviella* group” (with *sharpei*), and two single-species “groups” consisting of, respectively, *roccatii* and *rankinei*. The “ansorgei group” (in which *ansorgei* intergrades with *rhodesiae*) and the “*sylviella* group” sometimes treated as two additional species, latter exhibiting apparent vocal differences from others; in addition, occurrence of *rankinei* close to other races (*hellmayri* and *robertsi*) with no signs of intergradation suggests that this race, too, may warrant treatment as separate species; taxonomic review required. Other proposed races are *rothschildi* (described from Simba, in C Kenya), which is synonymized with *sylviella*, and *taruensis* (from Samburu, in coastal Kenya), synonymized with *robertsi*; supposed differentiating characters of both forms are insignificant. Eleven subspecies recognized.

Subspecies and Distribution.

A. c. ansorgei E. J. O. Hartert, 1905 – N & SE PR Congo, W DR Congo and C Angola.
A. c. roccatii Salvadori, 1906 – Uganda and W Kenya S to E Burundi and extreme NW Tanzania.
A. c. pallascens Ulfstrand, 1960 – W Tanzania (Kungwe-Mahali Peninsula).
A. c. winterbottomi C. M. N. White, 1946 – S DR Congo and adjacent NW Zambia.
A. c. rhodesiae W. L. Sclater, 1932 – SE DR Congo, N Zambia and SW Tanzania.
A. c. caroli (Sharpe, 1871) – S Angola, N Namibia, SW Zambia and Botswana.
A. c. sylviella Reichenow, 1904 – SC Kenya S to NE & C Tanzania.
A. c. sharpei E. J. O. Hartert, 1905 – SW Kenya S to N Tanzania.
A. c. robertsi Haagner, 1909 – E Tanzania, NE Zambia, Malawi and N Mozambique.
A. c. rankinei Irwin, 1963 – NE Zimbabwe.
A. c. hellmayri Roberts, 1914 – E & S Zimbabwe, S Mozambique and NE South Africa.

Descriptive notes. 8 cm; 6–7 g. Tiny, short-tailed greyish and buff passerine, some races olive and yellowish, with small, sharply pointed conical bill and quite strong legs and feet with short tibia. Nominate race has forehead and short supercilium dull buffy white, freckled with dusky (when feathers worn), dusky loreal line extending behind eye to upper ear-coverts; crown and upperparts, including side of neck, light grey (with hint of olive when plumage fresh); tail and wing feathers dark greyish-brown, narrowly edged greyish-buff, tertials fringed more olive-grey, greater upperwing-coverts narrowly tipped whitish

(forming narrow wingbar when fresh), wing and tail become bleached brown as feather fringes abrade; chin and throat whitish, breast washed light buff, becoming warmer buff on flanks and deep tawny-buff over ventral region; iris brown or blackish; bill blackish, becoming paler towards base and on cutting edges; legs slate-grey or blackish. Sexes similar. Juvenile is duller than adult, and paler buff on underparts. Races differ mainly in intensity of buff and grey in plumage, and in presence or not of yellowish and olive tones: *hellmayri* is close to nominate, but has throat and breast washed pale buff and is rather darker buff on ventral region; *robertsi* has slight olive wash above, is washed light yellow on throat and breast and yellowish-buff on lower underparts; *winterbottomi* is poorly differentiated, slightly more olive-toned above than previous (appearing intermediate between nominate and *rhodesiae*); *ansorgei* is green above, with yellowish forehead, whitish underparts washed pale yellow; *rhodesiae* is duller olive above than last, has whitish underparts washed pale buff over ventral region; *pallascens* is greyish-olive above, pale greyish below, lightly washed yellow and buff on lower underparts; *roccatii* has yellowish forehead and supercilium, otherwise greyish-olive above and pale yellow below, sullied greyish on throat, side of head and neck, becoming buffier over lower underparts; *sylviella* is grey above and buff below; *sharpei* is like last but more richly coloured; *rankinei* is almost slate-grey above, with whitish ear-coverts and supercilia, whitish below, lower underparts shading to pinkish-buff. **Voice.** Song a short phrase repeated 3–4 times, consisting of prolonged rising note, often preceded by 2–4 short ones; these delivered in several versions, a deep rasping “chi-chi-ch-dzzayzza” or similar, or much sweeter, weaker “tsi-tsi-chewee...”; some apparent geographical variation, e.g. *sylviella* song described as a thin yet metallic trill lasting c. 2–3 seconds, while that of *pallascens* said to be high-pitched trill which slowly fades. Calls include, among others, a buzzy “jaa” and a thin “jip”.

Habitat. Variety of woodlands; typically open woodland in more humid, lush conditions than those favoured by either *A. musculus* or *A. minutus*, but in parts of S Africa where latter species absent frequently in dry acacia (*Acacia*) savanna. In Kenya favours areas with moderate to high rainfall, generally at 1000–2200 m along E foothills of C & W highlands; formerly occurred also in coastal lowlands of SE Kenya. In Angola mostly above 1500 m, and in Malawi has been found as low as 80 m but commonest between 750 m and 1550 m. In S of range favours broadleaf woodland, especially miombo (*Brachystegia*), bushwillows (*Combretum*), cluster-leaf (*Terminalia*) and *Burkea*.

Food and Feeding. Diet small invertebrates, primarily insects and their larvae, but ticks (Ixodidae) also taken; also takes small fruits, and probes flowers of mountain aloe (*Aloe marlothii*) for nectar; nestling diet chiefly insect larvae, particularly caterpillars and beetle (Coleoptera) larvae. Forages in tree canopy, where very active, flitting from tree to tree, foraging upside down in leaf clusters and flowerheads; will feed also much lower, even down to ground level at times, chiefly when low-growing shrubs in flower. Forages in pairs or in small parties of up to seven individuals (presumed to be family groups), group-members keeping in contact with constant calling; readily associates with mixed flocks of other small birds, particularly white-eyes (*Zosterops*) and eremomelas (*Eremomela*).

Breeding. Breeds chiefly during rainy seasons; birds in breeding condition Aug–Apr in S Africa, Sept–Nov in Zambia and Oct–Nov in Malawi; Mar–Sept (largely the dry season) in DR Congo, whereas in E Africa mainly Feb, Apr–Jun and Sept–Dec (chiefly in rains, but some dry-season records). Monogamous; report of three individuals building same nest suggests that co-operative breeding also possible. Nest built by both sexes, an intricate construction, almost a pear-shaped

bag woven from spider webs and soft downy plant materials, extremely strong and long-lasting, with self-closing short tubular entrance (which has to be opened by the bird's foot), below this hidden nest-chamber is a more obvious false chamber entrance (more likely to be visited by potential predators); suspended up to 10 m above ground from fork in twigs (passing through top of nest) near tip of branch and often quite exposed. Clutch 3–6 eggs; incubation period c. 15 days (some estimates of 17–19 days); chicks fed by both sexes, during busy periods entrance hole may be left open for 5 minutes when parents repeatedly bringing in food, nestling period 22–28 days.

Movements. Chiefly sedentary, but seasonal movements in at least some parts of range. In winter descends into Zambezi valley in Zimbabwe; in Kenya sporadic in appearance at L. Baringo, suggesting that dispersal a regular habit.

Status and Conservation. Not globally threatened. Widespread but uncommon over much of its extensive range; locally scarce. Population densities in S Mozambique suggest up to 20,000 birds present, with 1 pair/50 ha in prime *Burkea* woodland on sandy soils in Limpopo Province. In Kenya decidedly uncommon or scarce, and population in coastal lowlands of SE extirpated in recent decades. Distinctive race *rankinei* of NE Zimbabwe very poorly known, and in particular need of taxonomic investigation. This species occurs in a number of national parks and other protected areas, and there is little reason for concern over its future.

Bibliography. Austin (1978b), Britton (1980), Cyrus & Robson (1980), Fry *et al.* (2000), Ginn *et al.* (1989), Hall & Moreau (1970), Harrap & Quinn (1996), Harrison *et al.* (1997), Hockey *et al.* (2005), Hoesch (1933), Irwin (1963, 1981b), Lawson (1961), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1960), Schüz (1990), Zimmerman *et al.* (1996).

9. Cape Penduline-tit

Anthoscopus minutus

French: Rémiz minute **German:** Kapbeutelmeise **Spanish:** Pájaro-moscón de El Cabo
Other common names: African/Southern Penduline-tit, Southern Kapok

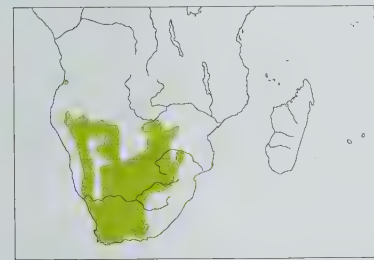

Taxonomy. *Sylvia minuta* Shaw, 1812, Heerenlogement, Western Cape, South Africa. Forms a superspecies with *A. punctifrons*, *A. parvulus*, *A. musculus* and *A. caroli*; possibly closest to *A. parvulus*, which may be its N counterpart. Geographical variation somewhat clinal, plumage colour darkening from N to S. Three subspecies recognized.

Subspecies and Distribution.

A. m. damarensis Reichenow, 1905 – CW & SW Angola, N Namibia, much of Botswana (except SW) and W & C Zimbabwe S to N South Africa (Limpopo Province).

A. m. minutus (Shaw, 1812) – W & S Namibia, SW Botswana and W & C South Africa (S to Western Cape, E to NW Free State and Mpumalanga).

A. m. gigi Winterbottom, 1959 – S South Africa (SW Free State S to W Eastern Cape).

Descriptive notes. 8–9 cm; 6–7.5 g. Tiny, short-tailed passerine with light greyish and yellowish plumage, small and sharply pointed conical bill, and quite strong legs with short tibia. N nominate race has forehead grizzled black and white, lowermost forehead and lores black, short supercilium white, short black line extending a little behind eye; crown and upperparts light brownish-grey; upperwing and tail darker grey-brown, tips of wing-coverts light grey, tertials with light grey-brown fringes (when fresh), rectrices with buffy fringes; wing and tail become bleached brown as feather fringes abrade; lower ear-coverts and sides of

head and neck, as well as chin and throat, whitish; entire underparts, including breast and undertail-coverts, pale buffy yellow; iris light brown to dark brown; bill grey or blackish, becoming paler towards base and on cutting edges; legs slate-grey or blackish. Sexes alike. Juvenile is duller and browner, less greyish, above and paler yellow below than adult, with fringes of tertials, flight-feathers and tail distinctly yellowish, rather than grey-brown. Races differ mainly in colour saturation: *damarensis* is paler and greyer above and paler yellow below than nominate, lacking latter's buffy tones; *gigi* is duller overall, being darker above and washed dull olive on underparts. VOICE. Song, from prominent perch or inside canopy, a high-pitched and often plaintive "chawee, chawee" or "tseeewee, tseeewee", repeated 6–8 times; also an abrupt "zwayt" during courtship flight. A number of other calls include bell-like "tillink", loud rasping "zizzit" (both are forms of contact call), and a thin "weess", repeated five or six times.

Habitat. Desert and semi-desert scrub, bushes and small trees, particularly open acacia (*Acacia*) woodland at desert edge, including rock outcrops (kopjes). In Botswana occurs also in isolated thorn bushes in C Kalahari, and has distinct preference for proximity of *Acacia karroo*.

Food and Feeding. Diet of small invertebrates, primarily insects and their eggs and larvae, also small spiders (Araneae); takes small fruits, e.g. of bony-thorn (*Lycium*), and small seeds have been found in stomach contents of some specimens. Nestling diet chiefly insect larvae, especially caterpillars and beetle (Coleoptera) larvae. Breaks into galls to reach larvae inside. Larger food items held in one foot and ripped apart. Forages in bushes and tree canopy, where very active, flitting from tree to tree, often probing while hanging upside-down, inspecting crevices in bark and in leaf clusters and flowerheads; although spends much time in low bushes, is rarely seen on ground. Forages in pairs or in small parties of up to seven individuals (presumed to be family groups), exceptionally as many as 21 in a flock. Often associates with mixed parties of small birds, including *A. caroli* in areas where ranges overlap; although it will join up with foraging *A. caroli*, latter seems not to join foraging flocks of present species.

Breeding. Laying in Jan–Feb in Namibia, Sept and Nov–Jan in Botswana, Oct and Feb in Zimbabwe, and in South Africa Oct–Jan in N, Jul–Oct in SW and Jun–Dec in S; those inhabiting most arid parts of range (e.g. Kalahari) more opportunistic, breeding when local conditions suitable; double-brooded, locally perhaps several broods in a season. Monogamous; often co-operative breeder, with helpers from pair's previous broods (in a study of several breeding units, eleven were pairs, two trios and one a group of four). Executes short courtship flight. Elaborate nest built by both sexes, in 20–35 days (replacement nest, if original destroyed, can be made in 13–20 days), an almost pear-shaped felt bag, woven from spider webs, wool and soft downy plant materials, extremely strong and long-lasting, has self-closing short tubular entrance (which has to be opened by bird's foot), below this hidden nest-chamber a more obvious hole to false chamber (more likely to be visited by potential predators), mouth of false chamber particularly thick and strong and useful as a platform on which parent braces itself while opening "hidden door" of real nest-chamber (which strongly sealed by a flap held tightly by spider webs); nest located 2–3 m above ground in top of thorny shrub, where attached by twigs through top of nest; other small birds, e.g. sunbirds (Nectariniidae) and larger serins (*Serinus*), often steal materials for building their own nests, some-

times causing owners to abandon nest entirely. Clutch 4–8 eggs, very rarely as many as 10 or 12 (perhaps product of more than one female); incubation by both sexes, with change-over every 30 minutes during day, period 15 days; chicks fed by both sexes, also by helpers if present, leave nest at 22–24 days; towards end of breeding season, two or even three broods roost with parents in nest or in that of another pair, or even in disused nest of another species, e.g. weaver (Ploceidae).

Movements. Sedentary. Occasional reports of individuals away from normal range suggest post-breeding dispersal out of the most arid habitats.

Status and Conservation. Not globally threatened. Widespread but not common over much of its extensive range. Studies in S Mozambique suggest population density of 1 pair/7.5 ha in mixed acacia woodland in Limpopo Province, whereas in South Africa density estimated at 27 birds/100 ha in Koeberg Nature Reserve (in Western Cape). Occurs in many other reserves and protected areas, e.g. Hwange National Park (in Zimbabwe), and there is little reason for any concern over its future.

Bibliography. Austin (1978b), Clancey (1997), Fry *et al.* (2000), Hall & Moreau (1970), Harrap & Quinn (1996), Harrison *et al.* (1997), Hockey *et al.* (2005), Hoesch (1934), Irwin (1981b), Skead (1959).

10. Forest Penduline-tit

Anthoscopus flavifrons

French: Rémiz à front jaune **Spanish:** Pájaro-moscón Frentigualdo
German: Goldstirn-Beutelmeise
Other common names: Yellow-fronted Penduline-tit

Taxonomy. *Aegithalus* [sic] *flavifrons* Cassin, 1855, Moonda River, Gabon. Has been considered a member of the superspecies formed by *A. punctifrons*, *A. parvulus*, *A. musculus*, *A. caroli* and *A. minutus*, but structural features, plumage coloration and rainforest habitat all suggest more distant affinities than exist among those five. Race *waldroneae* initially named "waldroni", but this is an incorrect original spelling. Three subspecies recognized.

Subspecies and Distribution.

A. f. waldroneae Bannerman, 1935 – N Liberia (N Lofa County, Mt Nimba), S Ivory Coast (forests of Taï, Fresco and Yapo) and SW Ghana (Goaso and Kakum forests).

A. f. flavifrons (Cassin, 1855) – SE Nigeria (Itu and Umuagwu), S Cameroon (Lolodorf, Elat and Aboulou), Equatorial Guinea (Mbini), N Gabon (Belinga, M'Bes, Makokou, M'Passa and Moondah estuary), N & SW PR Congo (Odzala and Nouabale-Ndoki National Parks; Kouilou) and N DR Congo (Equateur and Orientale Provinces).

A. f. ruthae Chapin, 1958 – E DR Congo (SE Kivu).

Descriptive notes. 9 cm; c. 7–9 g. Tiny plain olive-green passerine with yellowish forehead, small, conical and sharply pointed bill proportionately larger than that of congeners (and may give impression of having downward curve), quite strong legs with short tibia. N nominate race has golden-yellow forehead, sometimes lightly speckled (yellowish forehead very difficult to see in gloom of forest canopy); crown, nape and upperparts olive-green, wing and tail feathers blackish-grey, fringed olive-green, except for flight-feathers, which narrowly edged dull yellow; lores and sides of head and neck dusky olive, finely streaked olive-yellow,

paling on chin and lower ear-coverts; throat and underparts dull yellowish-olive, slightly mottled darker, yellowest on belly; in worn plumage becomes drabber as yellowish-green feather fringes abrade, exposing dusker feather bases; iris brown or blackish; bill blackish, becoming paler towards base and on cutting edges; legs slate-grey or blue-grey. Sexes similar. Juvenile is duller than adult, more greyish-green above, with narrower, buffer forehead band, underparts unmottled, washed buff on breast, distinctly yellowish on belly. Races differ mainly in intensity of yellow or buff tones in plumage: *waldroneae* is brighter yellowish-green above than nominate, and has breast paler and clearer yellow; *ruthae* has forehead buffy rufous and speckled with black, underparts paler off-white, washed light yellowish-buff (brightest on belly and undertail coverts), lower ear-coverts and throat cinnamon-buff, diffuse brownish patches at side of breast. VOICE. Not very vocal, or possibly most calls are high-pitched and pass unheard by humans. Calls include extremely high and thin "tseet" or "tit", sometimes accelerating into a trill; also an almost orthopteran-like "pshit", and a clear "tsi" which accelerates into a shrill, trilling "tsi-si-si-si...".

Habitat. Lowland evergreen forest, favouring forest edge, clearings and the like. Found also in well-grown secondary forest and overgrown plantations, especially those with flowering or fruiting trees, e.g. cotton trees (*Bombax*), figs (*Ficus*) and haronga (*Harungana*). Lowlands, to 600 m.

Food and Feeding. Food items include small insects and small pulpy fruits. Forages in middle and upper canopy, sometimes much lower; easily overlooked. Forages actively, partially concealed by leaves, quickly moving from one tree to another. Has a particular passion for clumps of mistletoe (*Loranthus*) and large sticky flowers of such trees as *Bombax*, where has been seen to forage inside the flowers themselves. Generally found in pairs or in small parties of 3–5 individuals, often scattered in canopy of one tree; readily associates with other small birds, such as the smaller sunbirds (Nectariniidae). An exceptional flock of at least 30 individuals reported; these were pulling apart the debris of old nests of red weaver-ant (*Oecophylla*) in low foliage. Has been seen also to break into old nests of social spiders (Araneae).

Breeding. Few observations. Birds in breeding condition (or in act of nesting) in Nov in Nigeria, Dec in Cameroon, Oct and Mar in Gabon, Oct in PR Congo and Jul and Oct in DR Congo. One observation of three or four birds visiting same nest, and another observation of three males (all with enlarged gonads) at or near nest on same day, suggest possible communal breeding. Nest typically suspended from twigs, very well made and can last for several years, a felt bag constructed from soft plant materials, e.g. *Bombax* ovary hairs (kapok) or cotton (*Gossypium*) heads, has self-closing short tubular entrance, and below this a false entrance (aimed at enticing predators, notably some predatory ants), with wall between real chamber and false chamber especially thick and impenetrable. No further information.

Movements. None documented, probably sedentary.

Status and Conservation. Not globally threatened. Not well known. Generally regarded as rare, and infrequently seen, but is probably not uncommon; clearly under-recorded, being difficult to locate among leaves of forest canopy owing to its small size and featureless coloration. Population assessments for such an elusive species difficult to make, but density of 3–5 pairs/km² estimated in Gabon; in complete contrast, only two sightings in 53 days in the field at a site in Ivory Coast (Taï Forest). Most mysterious is E race *ruthae*, which is known from only two specimens and a couple of sight records. Although much lowland rainforest has already been felled, this species' reliance on forest clearings with flowering trees makes it less vulnerable than are many other small forest

birds in its range. It is known to be present in several national parks, and at several sites its presence has been indicated by its obvious nests, which can remain intact for several years.

Bibliography. Bannerman (1948), Borrow & Demei (2001), Brosset & Erard (1986), Chapin (1954), Fry *et al.* (2000), Grimes (1987), Hall & Moreau (1970), Harrap & Quinn (1996), Mackworth-Præd & Grant (1973).

Genus *AURIPARUS* S. F. Baird, 1864

11. Verdin

Auriparus flaviceps

French: Auripare verdin **German:** Goldköpfchen **Spanish:** Pájaro-moscón Baloncito

Taxonomy. *Aegithalus* [sic] *flaviceps* Sundevall, 1850, "California" = Baja California, Mexico. Relationships uncertain. Has been placed with the tits and chickadees (Paridae) and in the past even with the previously monotypic Bananaquit (Coerebidae); results of research on DNA-DNA hybridization, however, suggest affinities with the New World gnatcatchers and gnatwrens (Polioptilidae), rather than with any other group. Nevertheless, this species does share a number of features with the penduline-tits, in particular nest details, vocalizations, bill shape and incomplete post-juvenile moult; pending further research, it is considered better retained in present family. Geographical variation confusing, and somewhat clinal, with several races intergrading; number of races could potentially be reduced following taxonomic review. Birds of this species in SW New Mexico (SW USA) and C Durango (NC Mexico) of uncertain race, provisionally included in *acaciurum*. Proposed race *fraterculus* (described from Chinobampo, in south Sonora, in Mexico) is synonymized with nominate. Six subspecies currently recognized.

Subspecies and Distribution.

A. f. acaciurum Grinnell, 1931 – SW USA (SE California, S Nevada, SW Utah, Colorado Valley of W Arizona, and SW New Mexico) and NW Mexico (S to S Baja California Norte, C Sonora, WC Chihuahua and C Durango).

A. f. ornatus (Lawrence, 1851) – S USA (SE Arizona, S & C New Mexico, Texas and SW Oklahoma) and NE Mexico (NE Sonora, N Chihuahua, Coahuila, N San Luis Potosí and CS Tamaulipas).

A. f. flaviceps (Sundevall, 1850) – NW Mexico (C Baja California, S Sonora and N Sinaloa).

A. f. lamprocephalus Oberholser, 1897 – NW Mexico (S Baja California).

A. f. sinaloae A. R. Phillips, 1986 – NW Mexico (NW Sinaloa).

A. f. hidalgensis A. R. Phillips, 1986 – NC Mexico (NE Jalisco, SC Guanajuato, S San Luis Potosí and C Hidalgo).

Descriptive notes. 10–11 cm; 6–8 g. A small dull grey tit-like passerine with small but quite stout, conical, sharply pointed bill and quite stout legs and feet. Male nominate race in fresh plumage (Sept–Feb/Mar) has yellow crown and brighter yellow forehead (yellow feathers have grey tips, becoming yellower with wear); nape grey, washed olive-yellow, grey upperparts with scattered yellow feathers on rump and back; wing feathers dark grey-brown, fringed and edged greyish-olive, except for reddish-chestnut lesser upwing-coverts and almost black primary coverts; tail dark grey-brown with olive-grey feather fringes, outermost

feathers fringed and tipped whitish; lores dark grey-brown, otherwise side of head, chin and throat dull olive-yellow, cleaner but paler yellow on throat, lower throat feathers tipped grey, side of neck and breast pale grey, shading into off-white of remainder of underparts; in worn plumage (breeding plumage, Apr–Aug), olive-grey tips of feathers lost, revealing brighter feather bases, especially on head and throat (which become quite bright chrome-yellow), wings and tail uniformly dark grey, or bleached brown by sun, sometimes a small reddish area on forehead as a result of extreme wear of yellow frontal band (which has red at very base of feathers); iris dark brown; bill blackish or dark blue-grey; legs dark blue-grey. Female is similar to male but duller (when sexes seen together), has lesser coverts browner and with greyish inner webs (visible only in hand), but individual feather wear and its effect on brightness of colour makes determination of sex (and age) difficult. Juvenile lacks yellow tones in plumage, appears completely grey, with paler underparts, bill fleshy orange with darker culmen and tip, soon darkening; juvenile male has lesser coverts olive or chestnut, juvenile female dull grey. Races vary mainly in brightness of coloration and in size: *ornatus* is somewhat larger and longer-tailed than nominate, also duller, with yellow areas less bright; *acaciurum* is paler overall than previous, with buff wash on upperparts and flanks; *lamprocephalus* is similar in size to nominate but upperparts paler, male tends to show small reddish patch on forehead (when plumage worn), crown and throat clear yellow; *sinaloae* has more extensive yellow on underparts in worn plumage (yellow extending over breast and sometimes even belly), also washed with yellow on upperparts, especially rump, lacks any obvious red on forehead; *hidalgensis* is very dark, with strong brown tones in plumage, has crown and throat area deep dull yellow. Voice. Usual call a sharp, loud "chip" or "tschk" (has been likened to sound made by two ball-bearings being knocked together), sometimes repeated to create an often rapid, staccato chatter; also a weaker "cheep" or "tseet" as contact call. Song far-carrying in early-morning desert silence, a loud, plaintive, whistled "tswee, tswee, tswee, tsweet"; some variations in number of notes and strength of delivery, and may be intermingled with other notes, including short twittering phrases.

Habitat. Desert scrub, especially woody bushes and thickets along dry watercourses. Prefers low-lying flat desert, in USA reaching 915 m in California, but as high as 1830 m in Texas; from sea-level to 2135 m in Mexico. Endures extremes of temperature, from 35°C, occasionally as high as 45°C, in the daytime to below freezing at night.

Food and Feeding. Small invertebrates, chiefly insects and spiders (Araneae); in autumn and winter small berries an important component of diet, especially as this desert species is said not to drink. Forages in foliage and around flowers of desert shrubs, inspecting bark and leaf clusters by swinging upside-down in tit-like fashion. Uses strong foot to pull twigs or leaves towards itself in order to inspect them. Uses foot also to hold down caterpillars and spider cocoons, breaking up food item and consuming the lot, as do parid tits. Usually found in pairs or in small family parties, holding both winter and breeding-season territories. Often joins mixed-species flocks, but perhaps only when these moving through its territory.

Breeding. Season early Mar to Jun in much of range, in Arizona and Texas sometimes late Feb and continuing to Aug/Sept; at least two broods in a season. Monogamous, solitary nester. Nest built by

both sexes, taking 4–6 days, male begins construction but female more actively involved towards end (particularly in lining cup), a large elaborate globe up to 20 cm in diameter and constructed from as many as 2000 spiny twigs woven around supporting branch structure (twigs placed with thorn side facing outwards to deter potential predators), entrance hole at side and obscured by projecting awning of twigs, twigs and spines woven into place with variety of soft materials, including feathers, cobwebs, soft seed pods, wool and leaves, interior of structure lined with feathers, often also some fur and wool; typically sited up to c. 3 m above ground near end of low branch of thorny shrub; during construction work, materials may be taken from old nests, including roost nests (pair builds a number of roosting nests throughout territory, partners not assisting each other, male building more than female, these nests often smaller than breeding nests, with shallower cup and more centrally placed entrance, and tending to be built around a branch fork). Clutch 3–4 blue-green eggs; incubation by female only, period 14–17 days; chicks fed by both sexes, mostly by female during first week, leave nest at 17–19 days; juveniles fed by parents, chiefly male, for a further c. 18 days, while female settles down to laying second clutch; fledged young often occupy roost nest with one of the parents.

Movements. Basically sedentary.

Status and Conservation. Not globally threatened. Patchily common over most of range, especially in Sonora and Baja California (Mexico) and in Arizona (USA), where considered to have increased with the spread of mesquite (*Prosopis*) scrub. Elsewhere in S USA it is less numerous, but not uncommon in parts of W Texas; uncommon in Utah and distinctly rare in N Texas and Oklahoma. The large number of nests produced by each pair can give false indication of abundance, making this a very difficult bird to census. It is known to be present in several national parks.

Genus *CEPHALOPYRUS* Bonaparte, 1854

12. Fire-capped Tit

Cephalopyrus flammiceps

French: Rémiz tête-de-feu **German:** Flammenstirichen **Spanish:** Pájaro-moscón Carirrojo
Other common names: Fire-capped Tit-warbler

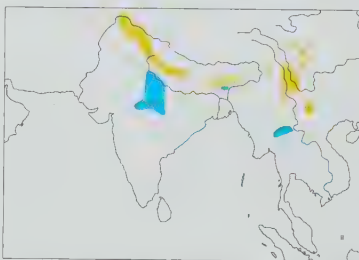

Taxonomy. *Aegithalus* [sic] *flammiceps* E. Burton, 1836, Himalayas = Mussoorie, Himachal Pradesh, India.

Relationships uncertain; formerly considered to be a kinglet (Regulidae). Placement in present family not entirely satisfactory, as this species differs from others in that it nests in tree holes, as do the true tits and chickadees (Paridae); in addition, it lays blue (not white) eggs, as also does *Auriparus flaviceps*. Nevertheless, song is typical of those of the genus *Remiz*, as is its small cone-shaped bill; pending further research, it is better retained in present family. Geographical variation slight and somewhat clinal, with E birds darkest; an additional race, *saturatus*, has been described from Sikkim, but has for long been synonymized with *olivaceus*. Two subspecies recognized.

Subspecies and Distribution.

C. f. flammiceps (E. Burton, 1836) – breeds N Pakistan (Gilgit) and Kashmir E to W Nepal; non-breeding NC India.

C. f. olivaceus Rothschild, 1923 – breeds E Nepal E to Bhutan and NE India (Assam, Arunachal Pradesh), and SC & S China (S Ningxia, SE Gansu, S Shaanxi, SC Sichuan, SE Xizang, Yunnan and W Guizhou); non-breeding in foothills, also (rarely) E Myanmar, NW Thailand and NW Laos.

Descriptive notes. 8.5–9.5 cm; 7 g. Tiny olive-and-yellow passerine with slightly notched short tail (two-thirds of which concealed by long uppertail-coverts) and small, slightly decurved, narrowly conical and sharply pointed bill; in plumage superficially resembling various leaf-warblers (*Phylloscopus*). Male nominate race breeding (Feb–Jul) has varying amounts of bright orange or red on forecrown, chin and throat; remainder of head and upperparts yellowish-olive, brightest on rump; uppertail dark olive-brown, feathers edged pale yellowish (clear wingbars and pale tertial fringes when feathers fresh); tail blackish-

brown, feathers fringed yellowish-green and tipped white (when fresh); lores and area around eye deep yellow, sometimes washed orange or reddish; underparts yellow, often quite bright, shading into bright orange or red of throat; iris brown to dark-brown; bill blackish, with some grey; legs dark blue-grey. Non-breeding male lacks reddish on crown, throat and face, resembles female but is brighter yellowish-olive above and yellower below, and has whiter throat. Female is duller than male, more greyish-olive on crown and nape, becoming more yellowish-olive on rump and uppertail-coverts, with greyish-white underparts washed pale yellow on belly and flanks; in breeding plumage becomes yellower on throat, face and breast, contrasting with off-white lower belly and ventral area. Juvenile resembles a dull female, having no yellow below and being very greyish-olive above, but by autumn many are quite bright yellow below (latter, however, possibly fresh-plumaged non-breeding males). Race *olivaceus* is darker green above than nominate, with yellow of underparts sullied olive, also male has smaller areas of orange on crown and throat. Voice. Song, from top of tall tree, less often in flight, a prolonged series of short trills and twittering sounds, seemingly a couple of phrases repeated at different speeds and pitches, rising and falling for several minutes. Contact calls include soft and mellow "whitoo-whitoo", high-pitched abrupt "tsit", sometimes repeated; flocks in winter keep up persistent twittering, could be confused with Tibetan Serin (*Serinus thibetanus*) if not seen well.

Habitat. Breeds in broadleaf mountain forest in W Himalayas, generally between 1800 m and 3000 m, favouring woodland of oak (*Quercus*), hazel (*Corylus*), elm (*Ulmus*) and walnut (*Juglans*) just below alpine coniferous zone; in Ladakh in alpine scrub, as well as in orchards and stands of poplars (*Populus*), during post-breeding dispersal ascending higher, up to 4000 m. In China breeds in fir (*Abies*), spruce (*Picea*) and rhododendron (*Rhododendron*) forests; on post-breeding dispersal, found at up to 4300 m in SE Xizang in Sept. On migration occurs also in gardens, parks, and willow (*Salix*) thickets by rivers and lakesides. In winter W population descends to plains of C India, where at-

tracted to parks and gardens with stands of large trees in fruit or flower; non-breeding distribution of E populations much less known, but seems to be foothill forest, rather than plains.

Food and Feeding. Small invertebrates, chiefly insects; some vegetable material also taken, e.g. observed to eat flower buds and young leaves, and also to take juice or sap exuded from banyan (*Ficus*) leaves. Forages in middle and upper canopy of tall trees; on passage also often in riverine bushes. Forages in tit-like fashion in canopy, swinging upside-down to investigate leaf bunches, or climbs along underside of branches, peering into nooks and crannies. Although feeds with tit-like agility, seems to “walk” with deliberate gait rather like a tiny parrot (Psittacidae), sidling along twigs to pull in rolled leaves with bill, and then, while holding leaf securely underfoot, prises it open. Holds larger prey items in foot, extracting soft contents. Usually found in small parties, but considerable gatherings of c. 100 individuals also reported; flocks may gather on bare trees on hillsides, looking like tiny finches (Fringillidae). Also joins mixed-species flocks, especially outside breeding season.

Breeding. Season early Apr to Jun, sometimes later, as juvenile reported as being fed on 31st Aug in Ladakh. Monogamous, solitary nester. Male performs short song flight, but more often prefers to deliver song from very top of tall tree. Nest seemingly built entirely by female, male in close attendance and often singing, a cup of small rootlets and dry grass, lined with finer grasses and feathers, normally placed 6–12 m from ground (sometimes as low as 1 m) in hole in tree, preferentially old hole of woodpecker (Picidae) or barbet (Capitonidae), where possible, and if necessary bird will enlarge existing cavity in soft wood. Clutch 3–5 eggs, mean 4; incubation believed by female only, she sits tight and puffs herself up and hisses if potential predator attempts to enter hole, no information on duration of incubation period; chicks fed by both sexes, although only female removes faecal sacs, no information on fledging period.

Movements. Short-distance and altitudinal migrant, W race moving farthest, but distributional division of the two forms in Nepal obscure. Arrives on breeding grounds in W Himalayas from late Mar to mid-Apr, departing in late Aug through Sept, although few reported in autumn (lack of red on fresh-plumaged males at that time of year making them less noticeable); some may remain in foothills, but most spread out over plains of C India (mainly E Rajasthan, S Uttar Pradesh and Madhya Pradesh). E race (*olivaceus*) less well known, but seems to move to foothills of mountains for winter, although some stray farther; rare non-breeding visitor (small flocks) in E Myanmar (S Shan States), NW Thailand and NW Laos. Often said to occur as a vagrant in Afghanistan, but this remains unproven.

Status and Conservation. Not globally threatened. Not well known; clearly much under-recorded, as it is difficult to locate among leaves of tall forest trees. Locally quite common in W Himalayas, especially Kashmir and Ladakh and in the Kulu and Simla districts of Himachal Pradesh, but decidedly scarce and somewhat irregular in appearance in Nepal; seen with regularity in Bhutan, notably in forest patches leading to the Pele La; in NE India, relatively few reports from N West Bengal or from hills flanking Brahmaputra valley in Assam and Arunachal Pradesh. In China generally poorly known, but reasonably widespread in C & S mountains. In winter months, nominate race should be looked for in gatherings of birds in fruiting trees; even trees in gardens of Taj Mahal, at Agra, have attracted the occasional small party in recent years. With such an elusive species it is difficult to assess population levels, but its tolerance of patchy forest and forest clearings with flowering trees makes it less vulnerable than many other small forest birds in its range. Known to be present in several national parks.

Genus *PHOLIDORNIS* Hartlaub, 1857

13. Tit-hylia

Pholidornis rushiae

French: Mésangette rayée **German:** Strichelköpfchen **Spanish:** Pájaro-moscón Estriado
Other common names: (Tiny) Tit-weaver, Tiny Tit-warbler

Taxonomy. *Diceum* [sic] *Rushiae* Cassin, 1855, Moonda River, Gabon.

Relationships uncertain, and systematic history remarkable. Originally described as a flowerpecker (Dicaeidae), it has since been placed at different times with the sunbirds (Nectariniidae), the waxbills (Estrildidae), the Old World warblers (Sylviidae), the tits and chickadees (Paridae), alongside the unrelated Green Hylia (*Hylia prasina*) in a new family Hylidae, and with the Australian honeyeaters (Meliphagidae). Placement in present family, on basis of assumed closer relations to genus *Anthoscopus*, provisional; fairly close similarities to other members in nest construction, roosting habits, vocalizations, juvenile plumage, general behaviour and basic appearance. Further research, especially DNA investigation, required. Birds of this species in SW Nigeria of uncertain race, provisionally included in *ussheri*. Four subspecies recognized.

Subspecies and Distribution.

P. r. ussheri Reichenow, 1905 – S Sierra Leone, SE Guinea, Liberia, S Ivory Coast, S Ghana, SW Togo and SW Nigeria.

P. r. rushiae (Cassin, 1855) – SE Nigeria and W & C Cameroon, S to Gabon.

P. r. bedfordi Ogilvie-Grant, 1904 – Bioko I (Fernando Poo).

P. r. denti Ogilvie-Grant, 1907 – SE Cameroon, N & SW PR Congo, NW Angola, C & E DR Congo and W & E Uganda; single record from SC Central African Republic.

Descriptive notes. 7.5 cm; 4.6–5.9 g. Tiny, short-tailed dusky passerine of upper canopy, with small, slightly decurved and pointed bill and bright yellow legs. Male nominate race has head, neck, mantle, scapulars and upper back dark brown, feathers narrowly fringed light greyish-buff, those of crown and nape also pale-tipped and slightly spiky in texture; lower back, rump and uppertail-coverts yellow, weakly washed olive, those of back and longer uppertail-coverts with dusky bases; upperwing dark brown, feathers narrowly edged pale greyish-buff, tail blackish-brown; chin to breast greyish-white, each feather with dusky shaft

streak, streaks on sides of head and breast broader and merging with darker upperparts; underparts from breast downwards dull yellow, washed lightly with olive, and dusky-streaked on flanks and ventral area; in worn plumage, becomes almost blackish on upperparts and breast as pale feather fringes lost; iris orange-brown to reddish-brown or red; bill blackish, yellow at base of lower mandible; legs bright yellow, pale claws. Female resembles male, but has pale grey-brown or creamy eyes. Juvenile is browner, more uniform, on upperparts, with rump and uppertail-coverts more olive and less clearly yellow, streaking on throat and breast finer and less obvious, often broken up into tiny spots or coalescing on malar region, lower underparts paler yellow, lacking streaks on flanks and ventral region, iris grey or dull brown, yellow at base of lower mandible more extensive. Races differ mainly in degree of olive tones in upperparts and boldness of streaking, especially on throat and breast: *ussheri* has feather fringes of upperparts more olive, rather than light buffy grey of nominate, and throat and breast streaking finer; *denti* has rump and uppertail-coverts and lower underparts almost orange-yellow, breast streaks fewer and softer; *bedfordi* is on average largest, has bold dark streaking on throat and breast, extending along flanks and across belly, also feathers of rump and uppertail-coverts dark-centred. **VOICE.** Song, from tree canopy (singer moving around in canopy), far-carrying, basically two clear trills, second trill faster than first, often preceded by two grating notes, the whole lasting c. 2 seconds. Calls include brief “ptu” or “pituu”, and shrill “psi”.

Habitat. Lowland secondary evergreen forest and fringes of primary forest, from sea-level to 1200 m (in Liberia). Favours forest edge, including riverbanks, and clearings. Also gardens and plantations with isolated large trees, especially silk-cotton trees (*Bombax*).

Food and Feeding. Small invertebrates, especially insects, scale-insects (Coccoidea) representing a good proportion of food items; small seeds found in stomach contents. Forages in middle and upper canopy, between 5 m and 15 m in tall forest trees, only occasionally coming lower. Travels in small parties of up to seven individuals, flying directly from tree to tree; quickly gleans items in or beneath foliage, spending concentrated effort at bunches of leaves or clusters of flowers; fond of mistletoe (*Loranthus*) clumps and vine tangles, through which it hops, flicking wings, while peering under leaves and pecking at bark crevices. Said not to associate with other small birds, but will feed alongside sunbirds at flowers. Because of its tiny size, sometimes becomes trapped in spider webs.

Breeding. Birds in breeding condition or nesting in Nov–Apr (most Jan–Mar) in Liberia; nest-building Apr and dependent fledglings Nov–Jan in Ghana, and fledglings in Dec in Nigeria, Mar in Gabon and Aug and Nov in Angola. Monogamous; possibly sometimes co-operative breeder, as four adults building a nest in Angola and two young fed by four adults there. Nest rather large for size of bird (15 cm in diameter), a very well-made ball of felted soft plant materials, entrance spout pointing vertically downwards (unlike nests of *Anthoscopus*, no false chamber), sited 3–20 m above ground and strongly bound to branch or mass of twigs; once reported as built into old nest of weaver (of genus *Ploceus*). Clutch 2 eggs; no information on incubation and fledging periods; up to five individuals reported as sharing a nest at night after end of breeding season.

Movements. None documented; probably sedentary.

Status and Conservation. Not globally threatened. Probably not uncommon; throughout range generally regarded as infrequently seen, but tiny size and dark general coloration make it difficult to locate among leaves of forest canopy, and species no doubt greatly under-recorded. Consequently, population level difficult to assess; in Kouilou basin, in SW PR Congo, estimate of 5–10 territories/km². Although much lowland rainforest has already been felled, this species’ reliance on forest clearings with flowering trees makes it less vulnerable than are many other small forest birds in its range. Known to be present in several national parks.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family AEGITHALIDAE (LONG-TAILED TITS)

- Small to tiny passerines with medium-long to very long tail, short rounded wings and short, stubby bill.
- 8.5–16 cm.

- Palearctic and Oriental Regions, with one species in Nearctic Region.
- Forest, forest edge, open woodland, scrub, parks and gardens.
- 4 genera, 13 species, 48 taxa.
- No species threatened; none extinct since 1600.

Systematics

The family Aegithalidae comprises four genera. The largest genus, *Aegithalos*, was established by J. Hermann in 1804, the monospecific genus *Psaltria* by C. J. Temminck in 1836, the monospecific *Psaltriparus* by C. L. Bonaparte in 1850, and the genus *Leptopoecile* by N. A. Severtsov in 1873.

Whether in the museum or in the field, the various members of the genus *Aegithalos* are obviously very closely related, and there is no suggestion that they should be anything other than congeners, but their relationship to *Psaltria* and *Psaltriparus* is less clear. The Pygmy Tit (*Psaltria exilis*) is poorly known, but soon after it was described, in 1836, it was allied with *Aegithalos* on the basis of, for example, its habits, calls and food. There has been no challenge to such a relationship, but thus far no genetic evidence is available to support it. The Bushtit (*Psaltriparus minimus*), on the other hand, is a well-studied species. It appears to be close to *Aegithalos* in many features, such as its vocalizations and breeding biology, and it has, indeed, been placed within *Aegithalos* by several authors, among them D. W. Snow in his 1967 treatment in J. L. Peters's *Check-list of Birds of the World*. More recent evidence from DNA–DNA hybridization, however, indicates a significant divergence between these genera, although they appear to be sister-groups, as suggested by F. H. Sheldon and F. B. Gill in 1996. Subsequent genetic studies have all confirmed this relationship. In 1990, using the results of DNA–DNA hybridization, C. G. Sibley and J. E. Ahlquist postulated that the ancestor of the Bushtit entered North America by means of a Bering Sea land-bridge 10–12 million years ago.

The position of *Leptopoecile* within Aegithalidae is uncertain. The White-browed Tit-warbler (*Leptopoecile sophiae*) was described by Severtsov in 1873, and the Crested Tit-warbler (*Leptopoecile elegans*) by N. M. Przevalski in 1887. The Crested Tit-warbler was perceived to be sufficiently distinct from the White-browed Tit-warbler for it to be placed in a new genus, *Lophobasileus*, erected in 1890 by T. Pleske. The differences between the two genera were, however, slight, and *Lophobasileus* was eventually synonymized with *Leptopoecile* by most authors, although the former genus was still being used by some authors as recently as 1987. *Leptopoecile* has traditionally been placed with the Old World Warblers in the family Sylviidae, despite several allusions to its being “tit-like”. Its resemblance to a tit (Paridae) is, of course, celebrated in the English vernacular name for the genus, tit-warbler, and even more so in the generic name of

Leptopoecile. As a point of interest, Severtsov, the great zoologist and explorer of Turkestan, gave the White-browed Tit-warbler the name of *Leptopoecile sophiae*, “Sophia’s Resplendent Titmouse”, in honour of his wife, Sophia Aleksandrovna.

In 1951, E. Mayr and D. Amadon commented: “More doubt exists as regards the central Asiatic *Lophobasileus* and *Leptopoecile*. These little birds suggest *Regulus*, but might be related to titmice, notably *Aegithalos*. We follow custom in leaving them near *Regulus* and *Phylloscopus*. Their mossy ground nest favors this assignment.” The perceptive comment about a possible relationship to *Aegithalos* was forgotten, and thereafter *Leptopoecile* was placed with the sylviid warblers, a position that came to be regarded, both by taxonomists and by birdwatchers, as the logi-

All but four of the 13 species in the family Aegithalidae are housed in the genus *Aegithalos*, which provides the family with its name. Members of *Aegithalos*, such as the **Black-browed Tit**, are rather consistent in morphology. These tits have very small bodies and short, rounded wings, which stand in contrast to a long or very long, graduated tail. The legs tend to be long and are slender, as is the norm for arboreal birds. The bill is short, rather deep and laterally compressed, and both mandibles are usually markedly curved. The irides of *Aegithalos* tits are usually pale, lending them a beady-eyed look.

cal one for it. Sibley and B. L. Monroe, for example, in 1990, placed it in the subfamily Acrocephalinae of their family Sylviidae. More recently, a relationship with Aegithalidae has been revived. On the basis of mitochondrial DNA data, a close relationship between *Leptopoecile* and *Aegithalos* was suggested by C. Sturmbauer and co-workers in 1998. This view was followed in 2003 by E. C. Dickinson, who put *Leptopoecile* in Aegithalidae; and it was corroborated in 2006 by P. Alström and colleagues.

Having established that the four genera that make up the Aegithalidae form a natural unit, one must then determine what is the relationship of this family to other passerine families. Despite their obvious differences from *Parus*, the genera *Aegithalos*, *Psaltria* and *Psaltriparus* remained for most of the twentieth century within the family Paridae, which had almost by default become the home for any small, fluffy, ten-primaried oscine passerine. There was, however, a recognition that the Paridae as then constructed was a heterogeneous, polyphyletic grouping, and C. E. Hellmayr, in 1911, elevated the different groups to the status of subfamilies. In 1921, E. Stresemann drew attention to the complete post-juvenile moult exhibited by *Aegithalos*, *Psaltria* and *Psaltriparus*, as well as by the parrotbill genera *Panurus* and *Paradoxornis*, whereas the members of the genus *Parus* have only a partial post-juvenile moult. In 1951, Mayr and Amadon again treated the groups as constituting separate subfamilies, stating that "The tits [Paridae] appear to be a polyphyletic group of genera placed together on the basis of superficial resemblance due to arboreal habits and a fine, more or less conical bill. Three groups can be distinguished...". The first of these groups was the "true titmice", consisting of the genus *Parus* and the closely related Sultan Tit (*Melanochlora sultanea*); the second contained the genera *Remiz* and *Auriparus*, of the modern penduline-tit family Remizidae; and the third group comprised the genera *Aegithalos*, *Psaltriparus* and *Psaltria*. Mayr and Amadon went on to state that, in their complete juvenile moult, cranial characters and, as described in 1890 by F. A. Lucas, nest structure, the long-tailed tits and bushtits differ radically from the Paridae. "The young hatch naked, while young of the true titmice are partly downy. They share several of these characters with *Panurus* and *Paradoxornis* and are perhaps nothing but an offshoot of the Timaliinae [babbler]. The fact that the parrotbills make a cup-like nest, while the nest of the present group is bag-like, is not, however, favorable to this suggestion." Five years later, how-

ever, in 1956, Mayr and J. C. Greenway, reporting on the work of an international committee appointed at the Eleventh International Ornithological Congress, did not subdivide the Paridae.

Going even further, C. Vaurie, following the suggestion of J. Delacour, elevated Aegithalidae and Remizidae each to family status, and this treatment was followed in 1967 by Snow and in 1977 by K. H. Voous. The latter author, however, wrote that "The recognition of a family Aegithalidae is a matter both of caution and of ignorance." Voous's comment reflected the fact that the major part of the only evidence available to taxonomists for the elucidation of the relationships of the long-tailed tits consisted of morphology and, to a lesser extent, behaviour. Morphological characters are extremely plastic and difficult to use in an objective manner, hence his caution.

In the traditional classification, the order Passeriformes is divided into two suborders, the Tyranni, or suboscines, and the Passeres, or oscines. Within the oscines, Aegithalidae was considered to be closely related to Paridae, as detailed above, and as a consequence the two were placed next to each other in world checklists. Genetic evidence became a factor in avian taxonomy with the advent of techniques involving DNA-DNA hybridization, the findings of which were summarized by Sibley and Ahlquist in 1990. Although relatively crude, DNA-DNA hybridization indicated very strongly that Aegithalidae was distinct from Paridae. More refined biochemical techniques have subsequently permitted the examination of mitochondrial genes and, more recently, nuclear genes, and much recent phylogenetic work has combined both in analytical investigations.

The advent of genetic evidence has resulted in a radical reorganization of passerine families. This work is continuing, but a consensus concerning much of the basic structure of the "new" evolutionary tree is rapidly emerging, and in 2006 K. A. Jönsson and J. Fjeldså reviewed 99 genetic studies in an attempt to construct a tentative "supertree" of relationships among all passerine birds. In their arrangement, the oscine passerines are divided into the two "parvorders" Corvida and Passerida, the Corvida being split into "Basal" and "Crown" sections. The Passerida is then subdivided into three superfamilies, the Muscicapoidea, the Passeroidea and the Sylvioidea, and all of these major branches are well supported by the available evidence. Jönsson and Fjeldså placed the Aegithalidae together with the Paridae in the superfamily Sylvioidea, with the treecreepers (Certhiidae) and the nuthatches (Sittidae) far removed in the superfamily

A stocky hind toe and long claw provide this **Black-throated Tit** with a firm grip on the slenderest of branches. This smart species fits the classic Aegithalos plumage mould, members usually being grey or brown above, with striking black and white facial markings, and often warm tones elsewhere on the body. Sexes are similar, but juveniles are duller. Juvenile Aegithalos tits undergo a complete post-juvenile moult—a strategy quite distinct from the partial moult of juvenile tits in the genus *Parus*, with which Aegithalos was formerly and erroneously grouped, in the family Paridae.

The **Northern Long-tailed Tit** is the most widespread and best known of the Aegithalidae. Plumage pattern and tones vary considerably across the species' range, which extends north to Fennoscandia, west to Ireland and Portugal, east to central Japan and south to Iraq. The 17 races fall into four groups, of which two are depicted here: the "nominate group" of northern Europe and Asia (above); and the "alpinus group" of Mediterranean Europe and south-west Asia (below). Apparent hybridization is known in areas of overlap between the groups, resulting in a confusing variety of plumage characteristics. Even without such intergrades, the array of plumage attributes in this species is impressive. Northern birds are strikingly crisp, with an unmarked white head, underparts and tertials contrasting with a jet black mantle and subtle pink scapulars. Other groups tend to be duller and less clean-cut. Most races have dark lateral crown stripes, with varying amounts of dark streaking on the sides of the head, the neck and the breast. Subspecies such as *irbii* of southern Iberia (below) have the mantle grey rather than black, and substitute a rosy flush to the flanks for pink scapulars. Eyelids also vary in colour from yellow to red. Intriguingly, one study found that mist-netted birds with red eyelids were more likely to give distress calls than those with yellow eyelids, suggesting that eyelid colour may reflect the internal "mood" of the individual.

The only member of the genus *Psaltiriparus*, the **Bushtit** is also the only representative of its family in North America. It shares several morphological characteristics with the genus *Aegithalos*, being very small and long-tailed, and possessing a tiny bill with a decurved upper mandible. The Bushtit is rather more drably attired than the *Aegithalos* tits, however. Its unmarked grey-brown upperparts and whitish underparts are washed grey, buff or pinkish. The ten races fall into three groups that differ mainly in colour tones, notably on the crown, and facial markings: some races have a striking black mask.

[*Psaltiriparus minimus californicus*, Kern County, California, USA.

Photo: Bob Steele/VIREO]

Muscicapoidae, within which they are placed in the same clade. It is apparent, therefore, that the long-tailed tits, in Aegithalidae, and the tits and chickadees, in Paridae, are not at all closely related to the nuthatches and treecreepers, but how close to each other are the two families of "tits"?

Jönsson and Fjeldså divided the Sylvioidea into 13 clades, although some of these were not well supported. The family Aegithalidae, including the genera *Aegithalos*, *Psaltiriparus* and *Leptopoecile*, is placed in clade 7, in which it forms a subclade; the other subclade comprises a mixed bag of "cettid warblers", including the genera *Cettia*, *Tesia* and *Abroscopus* and the Tithylia (*Pholidornis rufiae*). The family Paridae is placed in clade 2, thus revealing that the Paridae and the Aegithalidae are not very closely related.

Further work on passerine relationships is in progress. Within clade 7, Alström and colleagues have recommended the continued recognition of Aegithalidae as a family, and the formal recognition of a family Cettidae to cover the other subclade.

At the species level, there are several matters which would repay further investigation. The Silver-throated Tit (*Aegithalos glaucogularis*) of China has often been treated as conspecific with the Northern Long-tailed Tit (*Aegithalos caudatus*), an arrangement still preferred by some authorities. Its plumage, both as adult and as juvenile, is, however, distinctive, and this, combined with an absence of reports of regular intergradation or hybridization with Northern Long-tailed Tits in north-east China, supports its separation as a distinct species.

A more complex situation involves the White-throated (*Aegithalos niveogularis*), Rufous-fronted (*Aegithalos iouschistos*), Black-browed (*Aegithalos bonvaloti*) and Burmese Tits (*Aegithalos sharpei*). The last two of these are usually treated as conspecific, but the Burmese Tit is distinctive in appearance, being more like the White-throated Tit, and is geographically remote from the Black-browed Tit. Furthermore, both of these have sometimes been combined with the Rufous-fronted Tit or the White-throated, or all four species have been treated as conspecific. On the other hand, these four *Aegithalos* species seem to be fairly distinct morphologically, and, notwithstanding the fact that their ranges overlap only minimally or not at all, there is no evidence of intergradation or hybridization between any of them. For the time being, it seems best to treat these four species as forming a superspecies.

Further research may also lead to the splitting of one or more of the currently recognized species. The Black-throated Tit (*Aegithalos concinnus*), for example, may be found to consist of several distinct species. Moreover, the White-browed Tit-warbler exhibits marked geographical variation, and its four subspecies can be divided into two groups. The nominate race and *obscurus* are both relatively dark in plumage, whereas the two other subspecies, *major* and *stoliczkae*, are pale. The combined ranges of the dark races almost entirely encircle those of the pale races. In addition, the two groups may be separated ecologically, with darker populations at higher elevations and paler ones at lower altitudes, at least where the two groups overlap. If this

The **Pygmy Tit** is endemic to the island of Java. The only member of its genus, Java's smallest bird is a tiny, long-tailed aegithalid with a relatively stubby, broad-based bill. In contrast to other strikingly plumaged members of the family, the Pygmy Tit is drab greyish-brown above and dull pinkish-buff below. Sexes are similar, but the juvenile is still undescribed. This is perhaps surprising given that Pygmy Tits are fairly common at Java's favourite site for birdwatchers, Mt Gede and its adjacent botanical gardens. It thus remains a mystery for visiting birders to uncover!

[*Psaltia exilis*, Cibodas Botanical Gardens, Mt Gede, Java. Photo: Ketil Knudsen]

The two species of tit-warbler (*Leptopoecile*) are notable among the aegithalids in that they are very colourful, being adorned in blue, violet and chestnut. The male **Crested Tit-warbler** is a stunning creature, with a chestnut face, head sides, throat and upper breast, offset by delicate pink flanks and a lovely sky-blue mantle. Its tail and wings appear predominantly turquoise as a result of blue fringing to the individual feathers. Worn individuals have rather more washed-out plumage, which is reinvigorated following the annual complete post-breeding moult. This species is unique in the family for having a distinct, pointed white crest, as reflected in its English name.

[*Leptopoecile elegans*, Huzhu Beishan, Qinghai, China. Photo: Jussi Vakkala]

apparent ecological separation were to be confirmed, this would provide an argument for treating the groups of subspecies as constituting two separate species.

Morphological Aspects

Members of the genus *Aegithalos* are morphologically very homogenous and very well characterized. As their niches do not appear to be highly specialized, this suggests a recent radiation from an ancestral species, with little time for substantial differentiation. The body is very small. The bill is tiny, being short and conical, rather thick and somewhat laterally compressed; both the upper mandible and the lower mandible are strongly curved. The nostrils are rounded and covered in short feathers, the rictal bristles being inconspicuous. The legs are relatively long and slender, with the tarsal scutes often fused, and have a relatively stout hind toe with a long, strong claw. *Aegithalos* species often have eyes that are contrastingly pale, with a narrow ring of bare skin around each the eye, and in the case of the Northern Long-tailed Tit, at least, the colour of this skin can change depending on the age of the individual but probably also on its mood. The wings are short and rounded, with ten primaries, the outermost of which is much reduced, its length being approximately 40% of that of the longest primary. The tail is disproportionately long to very long, graduated and emarginated, with twelve, rather narrow feathers, the central pair shorter than the adjacent pair. *Aegithalos* species have soft, thick and lax plumage, giving them the appearance of a tiny ball of fluff, and they are usually strikingly patterned. Most species are grey or brown above, sometimes tinged pink, with prominent black and white markings on the head and a white rim around the tail. The underparts are white, often with a black or brown bib or collar and with a tinge of pink or buff on the flanks. The sexes are similar, but juveniles are distinct, being much duller and drabber than the adult and typically lacking the brighter pink, cinnamon and buff tones. Identification of adults is usually straightforward, and juveniles, although duller and less distinctive, are almost always found together with adults.

This genus has a very simple moult strategy. The adults undergo a complete post-breeding moult, and the juveniles a com-

plete post-juvenile moult. It is, incidentally, a rare strategy among temperate-zone passerines for the post-juvenile moult to be a complete one.

The Bushtit, sole member of the genus *Psaltiriparus*, is a tiny long-tailed bird with a very small bill. Its plumage is rather drab, although some individuals have a contrasting dark facial mask. Juveniles are most reliably separated by the shape of the outermost primary. The sexes are variably distinct, but there is considerable geographical variation in the plumage differences between them. The most reliable character for sexing individuals of this species is the eye colour, the male having a dark eye whereas the female is pale-eyed. This sexual difference may be evident a few days after fledging, but some individuals may take several weeks to change eye colour. Bushtits are generally easy to identify, but some juveniles require careful separation from the Verdin (*Auriparus flaviceps*). As with *Aegithalos*, both the adult post-breeding moult and the post-juvenile moult are complete.

The poorly known Pygmy Tit is very similar to *Aegithalos*. This tiny, long-tailed tit has a short, stubby, broad-based bill, but it is much duller than any member of the genus *Aegithalos*, although it is reminiscent of a juvenile Bushtit. The sexes are similar to each other, and it is thought that the juvenile is more or less identical to the adult.

In contrast to the other members of the family, the two tit-warblers comprising the genus *Leptopoecile* are brightly coloured, with areas of blue and violet in the plumage. The Crested Tit-warbler has a crest, making it the only member of the family to possess such an adornment. The nostrils are covered by folds of skin, and the feet and claws are conspicuously long. The sexes are distinct, even as well-grown nestlings, but juveniles are rather similar to adults. Adults have a complete post-breeding moult. A partial post-juvenile moult is reported for the genus; this includes a variable number of greater wing-coverts, tertials and, in the case of the Crested Tit-warbler, tail feathers.

Habitat

All members of the genus *Aegithalos* are essentially inhabitants of forest. Within this habitat, however, they favour a well-devel-

The two species of tit-warbler (*Leptopoecile*), tiny passerines with fairly long, graduated tails, are unique among the Aegithalidae in showing significant sexual dimorphism in plumage. In the **White-browed Tit-warbler**, the male (above) is vividly coloured, with extensive areas of lilac-blue, mauve and chestnut all catching the observer's eye. In contrast, the female (below) is drab greyish-brown, the only nod to colour being a faded chestnut crown and vaguely rufous flanks. This sexual dimorphism starts early, and is even apparent in mature nestlings. However, whereas sexual differences in the congeneric Crested Tit-warbler (*Leptopoecile elegans*) extend to eye colour, the male's being darker, both male and female White-browed Tit-warblers have fiery red irides. In addition to sexual dimorphism, there is also considerable plumage variation between the four races of White-browed Tit-warbler, with dark and pale subspecies pairs. These photos depict dark subspecies; pale-race males have predominantly buffy underparts. Where the races' ranges overlap, as in north-west China, dark birds occupy higher altitudes. This suggests an ecological separation that could justify elevation of each subspecies pair to full species.

Most aegithalids, particularly the core genus *Aegithalos*, are markedly sociable creatures.

The gorgeous **Black-throated Tit** is typical in being highly gregarious. It usually occurs in flocks, sometimes numbering 40 individuals. Although such large flocks are most frequently encountered outside the breeding season, small groups continue to forage together during the nesting period. These tend to comprise failed or early breeders, or non-breeders, and parties often tag along with mixed-species feeding flocks. Research into the well-studied Northern Long-tailed Tit (*Aegithalos caudatus*) suggests that flocks usually comprise families and any breeding helpers, and the same is likely to be true for other *Aegithalos* tits.

[*Aegithalos concinnus*.

oped understorey and shrub layer, and this tends to be best represented in edge habitats, as in natural systems along rivers and streams, and around clearings caused variously by fires, floods, wind-throw or the browsing of large herbivores. The long-tailed tits probably benefit from limited forest degradation and fragmentation by humans, and in Europe, at least, the Northern Long-tailed Tit has spread widely into semi-natural and cultural landscapes such as heathland, maquis, bushes and hedges in farmland, well-wooded gardens, parks, temple grounds and cemeteries. This species is even more widespread in such habitats in the non-breeding season. As a genus, *Aegithalos* has a preference for deciduous or mixed deciduous-coniferous forests, and even in mixed forests its members favour the stands of deciduous trees along watercourses and similar places. They mostly avoid pure coniferous forest, but in Siberia the Northern Long-tailed Tit is recorded in open forests of spruce (*Picea*), fir (*Abies*), larch (*Larix*) and Siberian stone pine (*Pinus sibirica*), and several of the Oriental species occur in pine woodland as well as in deciduous forest.

The Northern Long-tailed Tit is found mostly in the lowlands, below 1000 m, and only very locally extends to higher altitudes. It reaches its highest elevation, at 2000 m, in south-east Europe and Turkey. The closely related Silver-throated Tit is similarly a lowland species in the north of its range, but more montane in the south. All the other members of the genus are montane, with some altitudinal zonation. Thus, the Sooty Tit (*Aegithalos fuliginosus*) of central China breeds at the lowest altitudes, from about 1000 m to 2500 m, followed by the Black-throated Tit in the Himalayas and eastwards to Vietnam, at 1500–2500 m, and the White-cheeked Tit (*Aegithalos leucogenys*) in the western Himalayas, found above 1500 m and at up to sometimes 3660 m. Finally, the group formed by the White-throated, Rufous-fronted, Black-browed and Burmese Tits ascends even higher, typically breeding above about 2000–2200 m and extending to high elevations, in some cases to 4000 m or even 4400 m.

Of the remaining species in the family, the Pygmy Tit is found in montane forest above 1000 m, favouring conifers and other open trees, often on the forest edge. The Bushtit, by contrast, occupies a great variety of habitats, from forested mountains to arid brush, the latter including such habitats as, for example, pine-oak (*Pinus-Quercus*) woodland, second growth, riverine wood-

land and scrub, coastal chaparral and sage (*Artemisia*) scrub. Generally, however, this species prefers open mixed woodland with some evergreen foliage or shrubby understorey, and it avoids pure stands of conifers. It adapts well to suburban areas, and occurs down to sea-level in some coastal areas, but it is largely montane in the interior, ranging locally up to about 3500 m.

In the other genus of the family, the White-browed Tit-warbler is a bird of subalpine scrub at or above the tree-line, wintering at lower levels in both forest and scrub, while the Crested Tit-warbler breeds in coniferous forest and in the non-breeding season is occasionally found also in scrub. Both species occur at high altitudes, the White-browed Tit-warbler having been recorded at up to 5000 m.

The intense sociability of the aegithalids is not restricted to the daytime. By night, these tits roost communally. Flocks of **Bushtits** roost out in the open. Individuals will normally sit a few centimetres apart, but extremely cold weather drives them to huddle together as a means of conserving heat, and thus energy. While taking a break from foraging, juveniles, in particular, will also huddle together during the day—each vying for the prime central position.

VIREO]

Bathing is as essential for aegithalids as for any other woodland passerine. Washing feathers helps keep them in excellent condition. This activity, however, risks attracting the attention of avian and mammalian predators. These **Northern Long-tailed Tits**, seen above with a Common Blue Tit (*Cyanistes caeruleus*) and a Great Tit (*Parus major*), have thus taken care to choose a secluded woodland pool for their ablutions. Standing belly-deep in the water, the bird will briefly duck its breast and perhaps head underwater, roll back and forth, or shift from side to side, splashing water over itself by fluttering its wings in and out of the water. Fluffing out its feathers exposes the bare skin at the feather bases, ensuring that both plumage and flesh get a good soaking. A narrow black line down the centre of the otherwise grey mantle is characteristic of the subspecies *irbii* of southern Iberia.

[*Aegithalos caudatus irbii*, Benaolán, Málaga, Spain. Photos: Eduardo Alba]

General Habits

In the genus *Aegithalos*, the Northern Long-tailed Tit, with a range extending from Europe eastwards in a band through central Asia to the north-west Pacific Ocean, is relatively well known, but the remaining species, found in the Himalayas, China and South-east Asia, are poorly known and have not been the subjects of any systematic studies. Casual observations suggest, however, that their behaviour is very similar to that of the Northern Long-tailed Tit. All are very sociable, and are found in flocks throughout the year. Flocks of Northern Long-tailed Tits normally comprise approximately five to 30 individuals and are based around the parents and their offspring of the previous breeding season, together with any adult helpers that had been involved in raising the brood (see Breeding). These flocks are stable and "closed", and in winter each flock occupies a well-defended territory, the extent of which depends upon the number of birds that make up the group. Separate flocks do, however, occasionally amalgamate temporarily, and large groups of up to 300 or more individuals are reported at times.

In the late winter and early spring, the flocks break up, unmated females moving away and pairing with males in adjacent flocks, perhaps usually "switching sides" during territorial disputes. Display includes a butterfly-like jerky flight in which the presumed male flies up to a height of 5–6 m, alternately fanning and closing the tail before diving vertically downwards; three or four individuals may display in quick succession, or even simultaneously. Each pair sets up a loosely defended territory within the area occupied by the winter flock of which the male was a member, but both partners continue to roost with other members of the flock until the nest is sufficiently well built to be used as a roost, this usually being so when the dome is completed. They then roost in the nest until the young fledge. The flock may temporarily re-form in cold weather; alternatively, some individuals remain unmated in the early spring and may then be prone to wander.

Among Northern Long-tailed Tits, periods of quiet feeding alternate with noisy rapid movement, in follow-my-leader fashion, to a new area. The flight is weak and whirring, with rapid wingbeats, the speed and direction being rather irregular. When

about to cross an open area, the flock-members gather together, calling excitedly, before flying across the gap in single file. Individuals separated from the flock become agitated, uttering loud calls and searching for their companions.

When roosting, members of the Northern Long-tailed Tit flock huddle together on a horizontal branch, usually in a thorny thicket, each with the plumage ruffled such that it looks like a ball of feathers. The distance between individuals depends on the ambient temperature. On cold nights all are huddled very close and, in very cold weather, they may sleep in a hole in the ground, among roots or even in snow holes. The position that an individual occupies in the roost plays an important part in its chances of survival; those at the end of the line are the first to die in cold weather, and dominant birds therefore occupy the centre of the row. It has

All *Aegithalos* tits are highly vocal, a trait that is clearly related to their marked sociability. Flock members remain in contact by calling almost constantly as they move. The normal contact calls of the **Northern Long-tailed Tit** display variation typical of the genus, some vocalizations being high-pitched and weak, others short and abrupt, and yet others trilling and musical. Such communication reaches an excited crescendo when the group crosses an open area.

[*Aegithalos caudatus* caudatus,
Hanko, Finland.
Photo: Markus Varesvuo]

The aegithalid diet consists primarily of invertebrates, which the birds hunt throughout the year. *Aegithalos* tits have a particular taste for bugs (Hemiptera) and moth and butterfly (Lepidoptera) eggs and larvae. During autumn and winter, when insects in particular are less abundant, they take nutritional supplements in the form of small amounts of vegetable material such as seeds and even olives. This **Northern Long-tailed Tit** has just caught a bug which it is manoeuvring in its bill into a position suitable for swallowing. Should an *Aegithalos* tit catch a prey item too large to swallow immediately, the bird will happily hang from a twig by just one foot, hold the item in the other, then eat it piecemeal.

[*Aegithalos caudatus* caudatus,
Latvia.
Photo: Markus Varesvuo]

The long-tailed tits are arboreal birds, foraging from the shrub layer to the canopy, but rarely venturing down to the ground. They adeptly glean prey items from the surface of twigs, leaves and buds. On occasion, they may hover or even flycatch, but it is more usual to see these acrobatic passerines hang upside down from a branch, clinging on with a single foot. This **Sooty Tit** has just taken a prey item while foraging in the upper branches of a small tree. Like its congeners, it usually forages in flocks outside the breeding season, sometimes in tandem with other woodland passerines.

[*Aegithalos fuliginosus*,
Wanglang Nature Reserve,
Sichuan, China.
Photo: John & Jemi Holmes]

been suggested that such communal roosting is essential for the survival of this tiny passerine, and may be the main reason for its great sociability. When loafing during the daytime, pairs and members of the same social group similarly clump together, each in body contact with one or more others. Despite this species' extremely sociable nature, however, it has not been recorded as allopreening.

Although poorly known, the Pygmy Tit is, like *Aegithalos*, very active and it travels in small flocks. The Bushtit, too, is highly gregarious. It is usually found in flocks of about six to 40 and more individuals, moving through the vegetation in a follow-my-leader fashion, in much the same way as flocks of Northern Long-tailed Tits. Its flight is weak and usually over short distances, although it can fly up to about 200 m in one go, its

flightpath over these longer distances being undulating. Occasionally, it drops to the ground to collect nesting material or food, and it may hop short distances on the ground.

Once they are established, flocks of Bushtits are very stable, with little or no interchange between groups, and contain many of the same individuals from one year to the next. Non-members are usually driven off once the flock has formed. During the non-breeding season, these flocks range over large areas and have moderately well-defined territories, but the boundaries of different territories may overlap and chance contacts precipitate loud calling, pursuits and fights among males. Bushtit flocks may join mixed-species foraging flocks for short periods as the latter move through the area.

Flocks begin to break up in January and February, pairs usually then nesting within their flock's winter range, although some individuals may move, sometimes as much as 3–4 km, to nest and subsequently join the local flock there. During the early part of the breeding season, Bushtit pairs, and any helpers that they may have, maintain very poorly defended, non-exclusive areas around the nest from which other flock-members may be repelled, although they are often simply ignored. Once the eggs have been laid, there is no longer any defence of this area against other flock-members, which may enter the nest or steal nesting material. Breeding pairs continue to associate with all members of the flock throughout the breeding season, and move freely throughout the flock's foraging home range of about 100 ha; the "nesting home range" of the entire flock lies within this foraging home range, covering about 32 ha of it, and does not overlap with other nesting home ranges. Although flocks of Bushtits can be encountered throughout the breeding season, these generally consist of individuals which have not yet completed the nest-building stage and which return to the flock for overnight roosting. Some are composed of adults and young from early-breeding pairs.

Flocks of Bushtits roost in the open, among dense branches. Individuals are usually well separated from each other, but, when temperatures are below freezing, they perch in close contact, tightly huddled together, presumably as a means of conserving energy. In the winter and early spring, flocks often use the same roosting location night after night. During at least the early part of the breeding season, several flocks may coalesce to roost in

In terms of diet and foraging strategy, the two *Leptopoeile* tit-warblers are not dissimilar to the members of *Aegithalos*. They are active and agile foragers that prey upon invertebrates such as small insects and spiders, but may also resort to seeds and fruit outside the breeding season. This **Crested Tit-warbler** feeds high up in trees, rather like a kinglet or firecrest (*Regulus*), but will also clamber along small branches like a nuthatch (*Sitta*). In the non-breeding season, the Crested Tit-warbler sometimes joins mixed-species foraging flocks which descend from the trees into scrubland.

[*Leptopoeile elegans*,
Huzhu Beishan,
Qinghai, China.
Photo: Jussi Vakkala]

the same tree and the mated pairs return to the flock to roost; once the outer shell of the nest is complete, however, the breeding pair and any helpers will normally roost in the nest. Bushtits will at times huddle also during the day, while loafing, regardless of the temperature. Fledglings and juveniles, in particular, prefer to huddle during the day while loafing, often competing for central positions.

Of the two *Leptopoecile* species, the Crested Tit-warbler is confined to China and is very poorly known. The White-browed Tit-warbler, which has a broader distribution, has been well studied in Central Asia. The latter species is gregarious. It forms family parties after the breeding season, and several families may join together to create flocks of up to 25 and more individuals; it may join mixed-species foraging flocks. The pair roosts in the nest with the young and, as with *Aegithalos* species and the Bushtit, roosting strategies may be a key to survival in cold, high-altitude habitats, as it is often noted that White-browed Tit-warblers are sensitive to the cold. Thus, fledglings, even when they are able to fly well, remain close to the nest and roost there. In the Nan Shan, in north-central China, one pioneer observer found, on several occasions, two or three old nests close together and all containing droppings; these were presumed to be used for a time as roost-sites, and the young tit-warblers certainly use the nest for this purpose for 7–12 days after fledging. When an entire family is roosting in a nest, the structure is obviously under considerable strain and faeces may also accumulate in the bottom of it; most nests do not, therefore, last for long. E. P. Gavrilov and colleagues reported that, when they repaired collapsed nests that were no longer suitable for roosting, the tit-warblers started to utilize them again. There appears to be no information available on the roosting habits of White-browed Tit-warblers at other times of the year.

Relatively little has been reported with regard to the comfort behaviour of the Aegithalidae. Head-scratching by the Northern Long-tailed Tit and its congeners is by the indirect method, with the leg brought up over the wing. These species bathe by standing in water and splashing, but it is likely that some of them, at least, also perform foliage-bathing, in which the bird takes advantage of dew-laden or rain-sodden foliage. Bushtits, too, will bathe in water. Sunning has been recorded for the Northern Long-tailed Tit and is of the lateral style. There are no records of anting for any member of the family.

Voice

All members of the genus *Aegithalos* are very vocal, a fact undoubtedly related to the highly social nature of these passerines. Flock-members communicate almost constantly, emitting a variety of calls, often soft, clipped monosyllables and short silvery trills; some calls are quiet and subdued, whereas others are louder and relatively far-carrying. In contrast, they do not have a territorial song, but both sexes utter a quiet twittering and trilling, especially during aggressive encounters with conspecifics and during copulation. This "song" is seldom heard, and includes some of the call notes rapidly repeated in a jumbled, bubbling chatter.

While birds are able to extract water from their food, there is no substitute for the real thing. Water sources—whatever form they take—are thus of some importance. Pools, ponds and streams may hold larger quantities of water, but their terrestrial location requires would-be drinkers to compromise on safety. This **Northern Long-tailed Tit** has spotted an alternative—a melting icicle—and is hovering to sip drips of meltwater at its tip. Hovering, also termed "reguline" foraging, is also a technique used by *Aegithalos* tits to seek out insects hidden underneath foliage or trapped in spiders' webs.

[*Aegithalos caudatus*, Bavaria, Germany. Photo: Berndt Fischer/Oxford Scientific Films]

For **Northern Long-tailed Tits**, the breeding season tends to start in March. Following the break-up of non-breeding flocks in late winter, unpaired females enter the territory of a nearby flock and join available males. Once the pair have established a territory within the flock's home range, they spend up to 33 days constructing their elaborate nest. Both sexes collect nest material such as cobwebs, moss, lichen and animal hair. They weave this material into a compact dome that is roughly equal in height to the bird's length.

[*Aegithalos caudatus* *rosaceus*, Essex, England. Photo: Alan Williams/NHPA]

Bushtits take their time when constructing their nest. They investigate several potential nest-sites, affixing spiders' web at each until one takes the male's fancy. If the pair reuses material from earlier failed nests, construction may take as little as two weeks.

Building a nest from scratch, however, may take as much as seven weeks. The gourd-shaped nest itself can be as much as 30 cm tall with a diameter of up to 10 cm—an impressively large home for such a tiny passerine. The nest is constructed from materials as varied as twigs, moss, feathers and flowers.

Bound together with spiders' webs, the nest is lined with soft material such as plant down and hair; the parents continue to supplement the lining until their brood fledges.

Pairs are not too fussy about their nest's location: it can be as low as one metre above ground or as high as 30 m, and can be thoroughly concealed in dense vegetation or exposed to the elements.

The Bushtit has a complex breeding system. While monogamous pairs predominate and some pair-bonds span successive breeding seasons, up to a third of nests in some areas comprise co-operative breeding efforts. The brood helpers can be any age of either sex, but most appear to be males that are either unmated or unsuccessful breeders.

Such approaches to procreation appear to be most frequent during population booms.

Such approaches to procreation appear to be most frequent during population booms.

Such approaches to procreation appear to be most frequent during population booms.

The Early Birder]

In general, little is known about the breeding characteristics of Asian members of *Aegithalos*, the **Black-throated Tit** being the best studied. This species' breeding season starts as early as late February. Both sexes build the nest, construction lasting a couple of weeks. In common with congeners, the nest is a sphere, with an entrance hole towards the top on one side. It is built from a variety of plant material and animal hair, and bound together with spider webs, while feathers or plant down provide the soft lining necessary for effective insulation. The sexes probably share incubation. The pair are sometimes assisted by a helper, suggesting that co-operative breeding might be a regular strategy.

[*Aegithalos concinnus*.
Photo: Chien Te Wang]

The voice of the Pygmy Tit is very similar to that of *Aegithalos*, and the vocalizations of the Bushtit and the White-browed Tit-warbler are likewise reminiscent of those of the genus *Aegithalos*. These species, too, lack a territorial song.

Although the Crested Tit-warbler is, by comparison, very poorly known, its calls seem to be similar to those of its sole congener the White-browed Tit-warbler, and include a very thin, plaintive, descending "pseee". Other vocalizations of the Crested Tit-warbler are said to be reminiscent of those made by the Goldcrest (*Regulus regulus*), but it does utter a rather soft "dep" call at times.

Food and Feeding

Members of this family feed largely on invertebrates throughout the year. This diet is supplemented in the autumn and winter with variable but usually small amounts of vegetable material.

The *Aegithalos* species forage in the shrub layer and the canopy, and only rarely visit the ground. They may join mixed-species foraging flocks. They glean food items from the surface of twigs, leaves and buds. Although they are able to hover, and although they sometimes indulge in aerial flycatching, these techniques seem to be employed relatively seldom. These species are very active and agile, often hanging upside-down by one or both feet when seeking food. When dealing with an insect that is too big to be swallowed immediately, they will hang by one foot from a twig and hold the food in the other foot in order to peck at it. *Aegithalos* species are especially fond of bugs (Hemiptera) and the eggs and larvae of butterflies and moths (Lepidoptera). They occasionally take some vegetable material in the autumn and winter, and they have been recorded also as drinking sap. The young are fed exclusively on insects and spiders (Araneae). The members of this genus are not known to store food.

Little is known about the Pygmy Tit other than the fact that it forages at low levels and eats insects and spiders. The Bushtit, on the other hand, is far better known. It is very agile and active, foraging among the leaves and smaller outer branches of trees and bushes. It frequently hangs upside-down and by one foot, and it will use a foot to bend back a leaf so as to expose the central area of a foliage clump. It feeds mostly on small insects

and spiders, especially scale insects (Coccoidea) and other bugs, as well as beetles (Coleoptera) and the caterpillars and pupae of butterflies and moths; in addition, it consumes small quantities of seeds and fruit, perhaps especially during the winter months. Large caterpillars, those more than 1 cm in length, are repeatedly beaten against a branch until they are dead. Very rarely, a Bushtit will hold a prey item in one foot, with its tarsus resting on a branch, and use its bill to tear at the food. The young are fed with

Leaving its well-camouflaged and deftly concealed nest, this adult **Bushtit** heads off to find food for the young. Most Bushtits lay between four and eight eggs, clutch size appearing to increase with latitude. Larger clutches are thought to relate to breeding groups with two or more laying females. With the breeding cycle taking just one month from egg-laying to fledging, many Bushtits are double-brooded. Indeed, birds barely pause to recover strength between clutches, the female laying again within a few days of the chicks leaving the nest.

In many bird species, nestlings have evolved striking plumage, colours and behaviour in an attempt by the individual to receive a greater share of parental investment.

Depending on the species, chicks may call, open the gape wide—as seen with this **Northern Long-tailed Tit** brood—jostle, and/or quiver their wings to obtain more food quicker from the provisioning adults. For those species that gape, ornithologists used to consider that mouth colour made nestlings detectable to parents. Recent research reveals, however, that this is the function of the surrounding flange, rather than the gape itself.

Carton/Bios]

a high proportion of lepidopteran larvae. Bushtits are tiny birds, and their small body mass in relation to the surface area results in significant heat loss. They need to consume about 80% of their mass each day in order to avoid losing weight.

In the genus *Leptopoecile*, little is known of the Crested Tit-warbler. The White-browed Tit-warbler eats small insects and spiders, and also, especially in autumn and winter, some seeds and fruit. It is very active and agile, foraging mostly among herbs

and shrubs, and sometimes on the ground, where it investigates root tangles and lichen-covered rocks. Unlike *Aegithalos* species and the Bushtit, the White-browed Tit-warbler does not hang upside-down from branches, although there are some published statements to the contrary. Nor is it known to hold down prey with its feet and hammer at it with the bill.

Breeding

In the genus *Aegithalos*, breeding is well documented for the widespread Northern Long-tailed Tit but poorly known for most of the southern Asian species. The data that are available suggest, however, that the Northern Long-tailed Tit is typical of the genus. Despite its highly sociable nature, the Northern Long-tailed Tit is a solitary, monogamous nester, although some pairs have helpers. Like all members of the genus, it constructs a beautifully camouflaged domed nest. This is generally placed in a low thorny bush, but nests at greater heights, in a tree fork or against the trunk of a tree or hanging among the outer twigs of a conifer, have also been recorded, and there are a few records of nests being placed in holes in the ground. The nest itself, which is built by both sexes, is a compact, domed oval ball of moss, woven together with cobwebs and hair, and covered with numerous flakes of lichen, which serve as excellent camouflage. The average height of this structure is 160 mm and the average diameter 100 mm, and the entrance hole is placed to one side near the top. The nest is lined with a large quantity of small feathers, and the parents may continue to add these during the laying period.

Clutch size is typically around 8–12 eggs, with a range of 6–15. Clutches laid by Northern Long-tailed Tits at higher latitudes tend to be at the top end of this range. This trend is apparent also among the Himalayan and Chinese members of the genus, which, so far as is known, lay rather smaller clutches, normally up to six eggs. For the Black-throated Tit, which is relatively well known for the region, clutches of three to six eggs, and occasionally up to eight eggs, have been recorded in the Himalayas, with three in north-east India and north Myanmar and three to five in west Myanmar.

The Northern Long-tailed Tit's eggs are white, unmarked or with tiny reddish freckles, and measure approximately 14 × 11

With up to eight young to feed, adult **Bushtits** must spend the majority of breeding-season daylight hours foraging if they are to satiate the brood's incessant hunger. Spiders and small insects form the bulk of the nestlings' diet, and this adult is returning to the nest with quite a large caterpillar. Sizeable prey items are usually beaten against a branch to make them easier to swallow. Once fledged, juveniles normally only return to their natal nest if helping to feed their parents' second brood. Juveniles from all the nests in the flock's territory usually group together for foraging until all the broods have been raised, and the flock reunites for the winter.

mm. The female alone incubates, for a period of 12–18 days, during which she is fed on the nest by the male. The chicks are naked on hatching, and they have the interior of the mouth unspotted yellowish. Both sexes care for the young, which leave the nest after 14–18 days. The fledglings continue to be fed for at least a further 14 days, and the family-members then remain together as a unit throughout the winter. The species is single-brooded.

One aspect of the breeding biology of the Northern Long-tailed Tit that has been observed for only one other member of the genus is the presence of helpers. This may reflect a genuine difference among the various *Aegithalos* species, but it is more likely to be merely the result of a lack of data. The breeding pair is assisted by a variable number of helpers, up to eight having been recorded at a single nest. These are often adults which have failed in their own breeding attempt, and it has been noted that the later in the breeding cycle a nest fails, the more likely are the adults to become helpers at another nest. The male and female of a failed pair, when they become helpers, do not, however, assist at the same nest; in those cases in which the relationship has been established, the helper has been found to be a sibling of the male of the breeding pair, thus helping its brother to breed. Helpers assist in the feeding of the nestlings, and they continue to feed the young after they have fledged. In various studies, it has been found that the presence of helpers significantly increases the breeding success of the pair. The only other *Aegithalos* species for which helpers have been recorded is the Black-throated Tit. In a study of this species in north-east Sichuan, in central China, three nests were found to be attended each by a single helper; at all three, the helper took part in the incubation of the eggs and the feeding of the nestlings.

The other well-studied member of the family, the Bushtit of western North America and Mexico, has a markedly social breeding system. It is perhaps usually monogamous, and pairs can sometimes persist from year to year; conversely, a pair with a nest may split up and each member then mate with another individual, usually after the destruction or attempted takeover of a nest. The Bushtit is also at times possibly polyandrous, polygynous and polygynandrous, and breeding units recorded in Arizona have consisted variously of two or more males and one female, of two males and two females, and of one male and two females. Such systems may be most likely when population levels are high.

A variable percentage of Bushtit nesting attempts is attended by more than two individuals, with up to six recorded. These helpers may be rare in some years or in some regions, or they may be present at up to 40% of nests. Both high population levels and a high degree of predation may encourage such helping behaviour, since the number of birds in the flock which lack nests or the nests of which have been lost increases. Helpers assist at all stages, and are usually birds from the same flock, mostly the adult males from failed nests. After losing a nest, pairs or lone individuals can attempt to usurp an existing nest by overpowering its owners. If this takeover is successful, they become the new owners of the nest; if not, they may become helpers, the timing of the attempted takeover determining the potential for the laying or fertilizing of eggs by the helpers. Thus, if a male attempts to become a helper during the building, egg-laying or incubation stage, the resident male attempts to repel him; but if the intruder persists and is accepted, there is then often no distinction between the behaviour of the original male and that of the helper. Males that become helpers after the eggs have hatched do so uncontested, and up to five such males have been recorded at a single nest. The adults that join too late to contribute eggs to the nest function as non-breeding helpers, but they may have the opportunity to contribute eggs to a second nest. Helpers can also be adult males which do not have a mate or which have lost a mate, or, rarely, juveniles from the first brood in the nest.

Courtship begins in the flock and involves excited contact calls, trills, and posturing. Prior to copulation, the male chases the female and pecks at the region around the base of her tail and cloaca. During egg-laying, both partners continue to associate with other flock-members, and there is a clear potential for extra-pair copulations. DNA-fingerprinting of nestling Bushtits in 1992 in south-east Arizona, however, revealed only monogamy, but it should

While a bird bringing food to nestlings is often assumed to be a parent, this is not necessarily the case with the **Northern Long-tailed Tit**, as its sociable nature extends to its breeding system. Pairs breed monogamously but are often assisted by up to eight helpers. Helpers are usually adults whose own breeding attempt has failed; the later in the season the failure, the greater the chances that the disappointed would-be parents will follow their parental instincts by helping others provision their young. Not surprisingly in a relatively tight-knit flock, helpers and beneficiaries appear to be related, and are often siblings.

[*Aegithalos caudatus caudatus*,
Helsinki, Finland.

Northern Long-tailed Tits are ambitious parents, usually laying between eight and twelve eggs, though occasionally up to 15. As with other tits of the genus *Aegithalos* for which data exist, clutch size tends to increase with latitude. The nestlings require feeding almost constantly for the 14–18 days that they are in the nest. These tough demands keep both parents, and any adult helpers, busily foraging all day, every day, and probably explains why Northern Long-tailed Tits raise only a single brood. Parental care continues for the first fortnight following fledging, until the young reach independence. Thereafter, the family remains together throughout the autumn and winter, roaming across the territory of the wider flock. While most Northern Long-tailed Tit nests are sited just a couple of metres above ground in a thorny bush, the nest of the bird seen here is among a minority that are placed in a tree fork. This individual is of the subspecies *taiti*, which occurs from southern France south to central Iberia.

Unlike the cases of some other aegithalids, there is no evidence to suggest that the **White-browed Tit-warbler** ever engages in co-operative breeding. Instead, birds breed monogamously, without assistance from adult helpers. Records of *Leptopoecile* nests side-by-side suggest that the species might nest colonially, but may simply relate to the existence of additional roost-sites nearby. White-browed Tit-warblers lay between four and eight eggs, and these hatch after a fortnight. The parents take turns in brooding the chicks during the first week, and the young fledge after 18–20 days. The fledglings continue to be fed by their parents, as seen here, and roost in their natal nest for a further 7–12 days before becoming independent.

be borne in mind that this was in a year of very low population with no helpers, so that this finding is perhaps not typical.

Bushtits build a gourd-shaped nest 165–300 mm high and with a diameter of 65–100 mm, with the entrance hole usually at one side near the top. It is placed in a tree or shrub, usually fairly low down, and is suspended from the end of a single twig or branch in full view or, alternatively, is woven around and supported by several twigs and thus more concealed. The site is apparently selected by the male. The nest is constructed by both sexes from twigs, rootlets, moss, lichen, leaves, plant down, cocoons, grass, wool, feathers and flowers, all bound together with spider webs. The interior is lined with plant down, hair and feathers, and the adults continue to add material until the young fledge. Nest-building can be a prolonged affair, the duration of the work varying because of the reuse of material from nests which have been lost to predation or through bad weather. These may be dismantled and recycled in the same season, by the building pair or by other pairs, allowing later nests to be constructed more rapidly than initial nests. Indeed, if disturbed during nest-building, egg-laying or incubation, a pair of Bushtits will often desert, and the partners may then change mates and build a new nest. A single pair can make up to five nesting attempts in one season. Occasionally, one or both partners are expelled from an active nest by other Bushtits. First nests are almost always completed well before egg-laying commences but, if the nest is destroyed or the residents driven out, the pair will either attempt a takeover of another nest in the flock's nesting home range (see General Habits) or build a new nest, and the clutch may be started before completion of the second nest.

Clutches of 4–8 eggs are normal for the Bushtit. Larger clutch sizes, of up to 15 eggs, have been reported, but these may well be the result of more than one female laying in the same nest. As with the Northern Long-tailed Tit, there may be a latitudinal variation in clutch size, with the smallest clutches in Mexico and Guatemala. The eggs are plain white, and measure about 13.7×10 mm. Both sexes incubate, for a period of 12–13 days, and both also brood and feed the young, which are reported as being naked on hatching. The adults have been recorded as removing faecal sacs from the nest. The chicks fledge after about 18 days, but they are capable of leaving the nest earlier, after 14 days or so, if disturbed. They are fed for at least a further 14 days. Bushtits are normally double-brooded, the second clutch being laid about 3–4 days after

the first brood has left the nest, and when the fledglings are still dependent on their parents and helpers; occasionally, a new clutch is laid before the first brood fledges. Rarely, Bushtit nests are parasitized by Brown-headed Cowbirds (*Molothrus ater*).

Fledglings of this species never return to the nest except as visitors to a second brood or as helpers. Once fledglings have left the nest, juveniles from other flock-members' nests often show a marked interest in them and attempt to huddle with them. The juveniles from all of the flock's nests gather in large, mobile units, which contain adults and young of varying ages. Most juveniles remain with their flock over the winter period and go on to breed in the following spring, but some dispersal by first-year females takes place in the late summer or early in the next spring.

The nest of the Pygmy Tit is described as a pouch of leaves and grass, lined with moss, with a small entrance hole near the top, suspended from a branch. It is said to be reminiscent of the nest of a flowerpecker (Dicaeidae). The Pygmy Tit lays a clutch of two or three eggs, which are white with fine red spots. Nothing further is known of its breeding biology.

There are almost no data on the breeding biology of the Crested Tit-warbler, but that of the White-browed Tit-warbler is well known. The latter breeds in simple pairs, and there is no indication that it may be a social or co-operative breeder. Its nest is very like that of the Northern Long-tailed Tit, being an oval ball with the entrance hole to one side, well camouflaged with lichen and similar material, and copiously lined with feathers. Clutches laid by this tit-warbler vary from four to eight eggs, and these are pure white, spotted and flecked with light brown and reddish-brown. They are incubated by both sexes. On hatching, the young tit-warblers are naked, with delicate flesh-pink skin, and have an unspotted orange-yellow mouth and a yellow, unspotted tongue. Both parents brood the chicks and roost in the nest with them. After leaving the nest, the juveniles remain close to it and roost there for 7–12 days after fledging. The White-browed Tit-warbler is single-brooded, but, if a clutch is lost for any reason, it may lay replacement clutches.

Movements

Most members of the genus *Aegithalos* are sedentary, although populations breeding in mountain regions make seasonal

In central China, the nestling period of the **Black-throated Tit** has been found to last 14 days, and in this same region a study revealed that additional helpers sometimes assist in supplying provisions for the growing young. When the young birds leave the nest, they will remain dependent on their parents for at least another ten days before becoming fully independent. The juveniles seen here feeding on berries have yet to attain the striking black bib that is so characteristic of this species.

[*Aegithalos concinnus talifuensis*, Kunming Botanical Gardens, Yunnan, China. Photos: Li liwei]

altitudinal movements. The exception is the Northern Long-tailed Tit, which is resident over most of its huge range, but in north-central Siberia undertakes regular migrations or wanderings from late August through the winter until May. The bulk of these movements is directed to the south, but there is some northward dispersal in autumn, when flocks of hundreds of individuals have been recorded in central Siberia. The species' breeding areas are not totally abandoned, however. Rather, the centre of gravity of the population moves southwards as numbers in south Siberia are augmented by immigrants; a few may penetrate farther south, into Central Asia, but some may also remain in the north of the breeding range, or even farther north. Similar movements take place in eastern Asia, where the Northern Long-tailed Tit is a somewhat irregular migrant at Beidaihe, on the coast of north-east China, from mid-October to mid-November, wintering south of the breeding range in China and Japan and, more irregularly, to southernmost South Korea. Where migratory movements take place, it is probable that siblings migrate together.

Northerly populations of Northern Long-tailed Tits also exhibit irregular irruptive movements associated with high population levels in northern and eastern parts of the range. In such irruptions, which are sometimes on a massive scale, large numbers may reach Finland, the Baltic countries and eastern Europe, much smaller numbers appearing in western Europe. These movements reach a peak in mid-October, and some individuals, at least, return to the natal area in the ensuing spring. The crossing of water, however, is very much avoided by this species, and Northern Long-tailed Tits of the white-headed north-east European populations are therefore very rarely recorded in the British Isles. Furthermore, within Britain, this species is only an irregular autumn wanderer to offshore islands such as Orkney, the Outer Hebrides, the Isle of May and the Isles of Scilly.

Montane populations of the Northern Long-tailed Tit presumably undertake some altitudinal movements, and such elevational shifts are recorded also for all of the Oriental members of the genus. *Aegithalos* species, however, are rather hardy and are frequently observed at high altitudes during the winter months. Their downslope movements appear to be opportunistic, rather than regular migrations, and are partly post-breeding dispersal and partly a direct response to adverse weather conditions at higher altitudes.

In America, the Bushtit is basically resident, but in mountainous areas it exhibits some seasonal altitudinal migration, both upslope and downslope, as well as some regular dispersal into adjacent lowland areas. This dispersal perhaps involves individuals from the natal flock. During the non-breeding season, flocks of Bushtits may become semi-nomadic, wandering into warmer desert areas during cold spells during the winter months.

The Pygmy Tit is confined to western Java, where it is presumed to be resident, but it may move altitudinally. Both tit-warbler species are essentially sedentary, but some populations, those of the White-browed Tit-warbler in Central Asia, for example, do undertake marked and regular altitudinal movements. Depending on the severity of the winter weather, they may move up to 100 km away from their breeding areas and out on to the plains.

Relationship with Man

All members of the Aegithalidae are usually very tame. Perhaps it would be better to say that they appear "uninterested" in the presence of humans. The Northern Long-tailed Tit is increasingly recorded as visiting birdfeeders in western Europe, and in North America the Bushtit is found in suburban areas and often visits birdbaths. Apart from the fact that these birds are generally well liked by members of the public, however, aegithalids seem to have had little, if any, impact on humans.

Status and Conservation

None of the 13 members of the family is currently regarded as being globally threatened; nor is any listed as Near-threatened. Several of the species do, however, have a very restricted range. Good examples are the Pygmy Tit, the White-cheeked Tit and the Sooty Tit, confined to, respectively, west Java, the western Himalayas and central China; these three species would appear to be vulnerable owing to their small global ranges. Probably the clearest case, however, is that of the Burmese Tit, which has a tiny global range, confined more or less to Mount Victoria, in south-west Myanmar. Since this species has hitherto been treated

Most long-tailed tits are sedentary, the main exception being certain populations of the **Northern Long-tailed Tit**.

There is considerable post-breeding dispersal from north-central Siberia, with most departing birds heading south. A similar pattern occurs in eastern Asia, where birds sometimes winter as far south as South Korea.

Northern populations sometimes irrupt, high numbers of the white-headed race *caudatus* flooding south through Fennoscandia and the Baltic. Occasional vagrants even cross water bodies, for example reaching the British Isles.

caudatus,
Finland.

Photo: Dick Forsman]

as conspecific with the Black-browed Tit (see Systematics), its conservation status has not been formally assessed. It is apparently not common, as some recent visitors to Mount Victoria have experienced difficulty in finding this species, and it should probably be classed as, at best, Vulnerable.

There are, unfortunately, very few data on populations away from Europe and North America. Nevertheless, even though most members of the family seem to be well adapted to edge habitats, and thus able to cope with some degradation and fragmentation of forest habitats, the southern Asian species must all have suffered some declines as a result of total habitat loss.

[*Aegithalos fuliginosus*,
Wanglang Nature
Reserve,
Sichuan, China.
Photo: John & Jemi
Holmes]

In Europe, where many bird species have been very well studied, the population of the Northern Long-tailed Tit has remained more or less stable in recent years. Some minor changes have been detected along the edges of its range, and there can be marked annual fluctuations caused by variable weather conditions during the winter months.

Ornithological study is well advanced also in North America, where the range of the Bushtit has been shown to be slowly expanding northwards and westwards. Owing to this species' social nature, its population densities are difficult to measure, but a density 19.8 pairs/100 ha has been reported in north Arizona. As with the Northern Long-tailed Tit in Europe, the total numbers of Bushtits vary from year to year, probably as a result of natural factors such as weather conditions and insect abundance. Especially wet winters can have an adverse effect on the overwinter survival of this species. The population in California increased in the first half of the twentieth century, perhaps the result of an increase in the amount of suitable habitat facilitated by the clearing of dense forest and the planting of smaller trees and shrubs. More recently, Bushtit populations have remained stable or have declined slightly. It is possible that such declines have been caused by the loss of open oak woodlands.

General Bibliography

(2007h), Baker (1997), Balatsky (1999), Bent (1946), Berndt (1984a), Bock (1994), Bruce *et al.* (1996), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Cramp & Perrins (1993), Dickinson (2003), Dickinson *et al.* (2006a), Eck & Martens (2006), Gavrilov *et al.* (1968), Glen & Perrins (1988), Guo Guiyun *et al.* (2006), Harrap & Quinn (1996), Hatchwell, Ross, Chaline *et al.* (2002), Hatchwell, Ross, Fowle & McGowan (2001), Hatchwell, Russell *et al.* (2004), Hellmayr (1911), Hudde (1993), Jönsson & Fjeldså (2006a), Löhrl (1964), Lucas (1890), MacColl & Hatchwell (2003), Mayr & Amadon (1951), Mayr & Greenway (1956), McGowan, Hatchwell & Woodburn (2003), McGowan, Sharp & Hatchwell (2004), Neufeldt (1970), Pleske (1890), Rasmussen & Anderton (2005a, 2005b), Roberts (1992), Sheldon & Gill (1996), Sibley (1996), Sibley & Ahlquist (1990), Sibley & Monroe (1990, 1993), Sloane (1992, 1996, 2001), Snow (1967a), Stresemann (1921), Stresemann *et al.* (1937), Sturmbauer *et al.* (1998), Vaurie (1957a, 1957d, 1959), Voous (1977), Watson (1986), Wunderlich (1989a, 1989b, 1991a, 1991b).

While population data are regrettably incomplete for most aegithlids, none is listed as globally threatened at present. Several are, however, classified as restricted-range species. One example is the **Sooty Tit**, which occurs only in the Central Sichuan Mountains Endemic Bird Area in China, where it is uncommon for the most part. This species' range is thought to cover as little as 20,000 km², which certainly suggests that it could be susceptible to substantial further reduction in the local forest cover.

Genus *AEGITHALOS* Hermann, 1804

1. Northern Long-tailed Tit

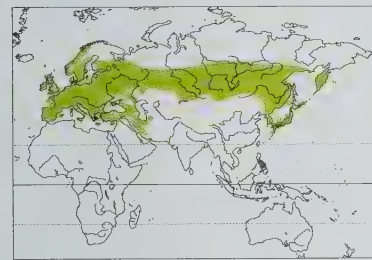

Aegithalos caudatus

French: Mésange à longue queue **German:** Schwanzmeise **Spanish:** Mito Común
Other common names: (Eurasian) Long-tailed Tit, Long-tailed Bushtit; Alpine Tit (*alpinus*)

Taxonomy. *Parus caudatus* Linnaeus, 1758, Sweden. Often treated as conspecific with *A. glaucogularis*, but plumage distinctive, and no reports of regular intergradation or hybridization with latter species in NE China (apparent “intergrades” recorded as migrants in coastal Hebei, but origin and status of these unknown). Marked geographical variation. Races fall into four groups: “n nominate group” in N Europe and Asia, “*europaeus* group” (including also *rosaceus*, *aremorius*, *taiti*, *macedonicus*, *tauricus*) in S & W Europe, “*alpinus* group” (including also *iribii*, *italiae*, *siculus*, *tephronotus*, *major*, *passekii*) in Mediterranean Europe and SW Asia, and “*trivirgatus* group” (incorporating *kiusiuensis*, *magnus*) in S Korea and Japan (“*europaeus* group” and “*trivirgatus* group” are morphologically similar and usually combined, but marked geographical separation strongly suggests different origins). Where groups meet there are extensive areas occupied by variable populations of apparent hybrids, these areas of hybridization considered to be zones of secondary intergradation (where populations have met relatively recently). Nominate race intergrades with *europaeus* in Denmark, E Germany, S Poland, S Ukraine and N Romania, and with *magnus* in Korea; *aremorius* intergrades with *taiti* in WC France; *taiti* intergrades with *iribii* in C Spain and Portugal; and *europaeus* intergrades with *aremorius* in W France, with *taiti* in SW France, with *italiae* on S slopes of Alps, and with *macedonicus* in S of former Yugoslavia and S Bulgaria. Birds of this species breeding in Iraq and Syria of uncertain racial identity, provisionally included in *tephronotus*. Other proposed races are *sibiricus* (C Siberia), *kamtschaticus* (Kamchatka, in E Russia) and *japonicus* (N Japan), all poorly differentiated and thus synonymized with nominate; and *pallidolumbo* (Shikoku, in S Japan) and *tarihoae* (Cheju I, off S Korea), both merged with *trivirgatus*. Seventeen subspecies recognized.

Subspecies and Distribution.

- A. c. caudatus* (Linnaeus, 1758) – breeds from Fennoscandia (N to c. 70° N in Norway, locally to 66° N in Finland) and NE Europe (Poland) E in broad band through Siberia to E Russia (Kamchatka), Sakhalin I, S Kuril Is and N Japan (Hokkaido, Rebun-to and Rishiri-to), extending S to N Kazakhstan, N Mongolia, NE China and N Korea; non-breeding also S to E China (Hebei) and C Japan (SC Honshu).
- A. c. rosaceus* Mathews, 1938 – Britain and Ireland.
- A. c. aremorius* Whistler, 1929 – NW France (E to Centre, S to Poitou area), I d’Yeu and Channel Is.
- A. c. taiti* Ingram, 1913 – SW & S France (including I d’Oléron) S to C Spain and Portugal (S to Tejo valley), also Mallorca.
- A. c. europaeus* (Hermann, 1804) – NE France E to Germany, S to N Italy, Serbia, W Romania, Bulgaria and NW Turkey (N Thrace).
- A. c. macedonicus* (Dresser, 1892) – Albania, Macedonia, mainland Greece, S Bulgaria and NW Turkey (SW Thrace).
- A. c. tauricus* (Menzies, 1903) – S Crimea.
- A. c. iribii* (Sharpe & Dresser, 1871) – S Portugal (S of Tejo valley), S Spain and Corsica.
- A. c. italiae* Jourdain, 1910 – mainland Italy and SW Slovenia.
- A. c. siculus* (Whitaker, 1901) – Sicily.
- A. c. tephronotus* (Günther, 1865) – Lesbos and Samos (E Greece), W & C Turkey (including extreme E Thrace), also Syria and extreme N Iraq.
- A. c. major* (Radde, 1884) – Caucasus (from N foothills of Great Caucasus), NE Turkey (E at least from Sebinkarahisar), Georgia, Armenia and N & C Azerbaijan.
- A. c. alpinus* (Hablitzl, 1783) – SE Azerbaijan (Talis Mts and Lenkoran lowlands), N Iran (E through Elburz and S Caspian districts to about Gorgan) and SW Turkmenistan (Kopet Dag).
- A. c. passekii* (Zarudny, 1904) – extreme SE Turkey and W Iran (Zagros Mts S to Fars).
- A. c. magnus* (A. H. Clark, 1907) – C & S Korea and Tsushima I.
- A. c. trivirgatus* (Temminck & Schlegel, 1848) – C Japan (Honshu, Awa-shima, Sado and Oki) and Cheju I (off S Korea).
- A. c. kiusiuensis* Nagamichi Kuroda, 1923 – S Japan (Shikoku, Kyushu and Yakushima).

greater coverts broadly tipped and fringed white; flight-feathers dark brown, tertials and secondaries broadly fringed whitish; iris dark hazel, eyelid yellow to red (yellow commonest, but colour probably also reflecting mood); bill black; legs blackish-brown. Sexes alike. Juvenile is darker overall than adult, rear lores to cheek and ear-coverts dusky (accentuating pale eyering), only centre of forehead and crown whitish, mantle and back brown, pinkish tone confined to distal half of scapulars, tail shorter and blackish-brown, white in outer tail reduced and sullied brownish, inner greater coverts more narrowly fringed and tipped buffish-white, flight-feathers paler and browner, underparts dirty white, belly with buff tinge. Races exhibit marked variation, mostly in plumage pattern and tones, “*europaeus* group” and “*trivirgatus* group” slightly duller than nominate and with broad blackish lateral crownstripe, but great individual variation, “*alpinus* group” also very variable, head pattern as “*europaeus* group” (although sides of head and neck streaked darker) but upperparts mainly grey with little or no pink, blackish confined to band across upper

mantle, often a blackish spot on throat, and has wing and especially tail shorter: *rosaceus* is smaller than nominate, has forehead to nape white, irregularly spotted dark brown, band from just in front of eye (occasionally from bill) to side of nape dull black, ear-coverts and side of neck finely streaked dark brown, pale areas above darker dull pink, less white in wing (edgings narrower), underparts off-white, flanks dull vinaceous pink, sometimes faint necklace of darker streaks across upper breast; *aremorius* has centre of crown and underparts whiter than previous, lateral crownstrokes broader and blacker; *taiti* is small and dark, with lateral crownstrokes even broader and blacker, upperparts (especially rump) blacker, with less pink; *macedonicus* resembles previous, but gorget better marked, and lateral crownstripe extends farther forward, often to bill; *europaeus* typically resembles *rosaceus* but is brighter and paler, with lateral crownstripe narrower, crown, cheek, ear-coverts and underparts clearer white, but very variable, lateral crownstripe sometimes broken or almost absent (thus resembling nominate, but always at least some indication of dark stripe) or very broad (leaving only small white patch in centre of crown); *tauricus* resembles last, but lateral crownstripe blacker and better defined, mantle blacker with reduced (and paler) pink, scapulars often greyish; *trivirgatus* also is similar to *europaeus*, but white areas purer white, black on upperparts restricted to upper mantle, lower mantle paler and with greater admixture of brighter pink; *kiusiuensis* is like previous but darker, with gorget less distinct or lacking; *magnus* is close to nominate, but with blackish lateral crownstripe and usually a well-marked gorget of blackish spots; *iribii* has narrow black band across upper mantle, rest of mantle and scapulars grey, scapulars sometimes tinged pink; *italiae* is similar to previous, but broader black band on upper mantle, slightly darker slate-grey lower mantle, and with scapulars more broadly tipped pink; *siculus* also is similar, but lateral crownstripe duller and browner, white centre of crown washed buff, dark band on upper mantle reduced and more brownish-black, rest of upperparts paler and greyer, virtually lacking pink, may show vague sooty-black spot on lower throat; *tephronotus* resembles previous, but lateral crownstripe black, dark upper-mantle band lacking or reduced to a small brown spot, underparts buffish with well-defined blackish throat spot; *major* is similar, but lateral crownstripe blackish-brown, centre of crown whiter (not buffish) with a few small brown streaks, band on upper mantle brown to black and varying in width, rump bright pink, breast white, lower belly and flanks brighter pink, dark spot on lower throat faint or absent, tail relatively long; *alpinus* is like *tephronotus*, but centre of crown brown-streaked buffish-white, upperparts darker, upper mantle grey with some admixed black, lower throat usually sooty, underparts washed buffy brown (pink flanks contrasting little); *passekii* resembles last, but overall rather paler, especially below, with only faint brown wash on belly, centre of crown white (not buff), and lacks gorget (although has dark throat spot). VOICE. Very vocal. Usual contact calls a high-pitched, pure, quiet but penetrating “see-see-see” (given especially in flight, particularly when flock in rapid movement, and by individuals isolated from main flock); fuller and flatter, clipped “tup”, usually interspersed with single high, thin “tset” notes; short, explosive, slurred, rattling trill, falling in pitch towards end, “tsirr” or “tsirrup”, given in alarm or excitement (frequently without apparent provocation); louder, harder, high-intensity versions given during conflicts between flocks. No territorial song, but occasionally utters quiet twittering and trilling, combining “tup” and “tsirrup” notes as well as scolds, sometimes in rather structured form (resembling song of an *Acrocephalus* warbler) and sometimes as a more jumbled collection of notes; this “song” given by both sexes, especially during aggressive encounters with conspecifics, during copulation and nest-building and when feeding young.

Habitat. Deciduous and mixed woodland with well-developed shrub layer, especially willows (*Salix*), favouring edge habitats. Also riverine woodland and, perhaps especially in W Europe, scrub, heathland with scattered trees, bushes and hedges in farmland, and well-wooded suburban parks, cemeteries and gardens. In Mediterranean region also in maquis and open pine (*Pinus*) forest. Otherwise, avoids pure stands of conifers in W of range, but noted in open forests of spruce (*Picea*), fir (*Abies*), larch (*Larix*) and Siberian stone pine (*Pinus sibirica*) in C Siberia (probably especially forest edge or riverside areas where an admixture of broadleaf trees). In Europe usually below 1000 m, although found at up to 1200 m in Hungary and very locally to 1800 m (rarely, to 2120 m) in the Alps, but more montane in SE, breeding to 2000 m in Greece (though commonest at 200–1000 m), 2000 m (mainly 100–1300 m) in Turkey and 1500 m in Caucasus; to at least 1830 m in Iran; in Japan mainly at 500–1600 m, wandering to lower levels in winter; primarily montane also in China, where noted at 780–1100 m (extremes 400–1800 m) in the Changbai Shan (Jilin).

Food and Feeding. Food throughout year largely invertebrates; occasionally also seeds, buds and even olives (*Olea*) and peanuts taken, especially in autumn and winter; recorded as drinking sap. Forages mostly in shrub layer and canopy, only occasionally on ground, delicately picking items from surface of twigs, leaves and buds. Can hover, and sometimes flycatches. When dealing with an insect too big to be swallowed immediately, will hang from a twig by one foot and hold the item in other foot in order to peck at it. Tame and very gregarious, for most of year forming stable flocks of c. 3–30 individuals based around parents and offspring of previous breeding season, together with any adult helpers that had been involved in raising brood. Periods of quiet feeding alternate with noisy rapid movement, in follow-my-leader fashion, to a new area; when traversing open areas, flock-members gather together, calling excitedly, before crossing over in single file. Flocks occasionally amalgamate temporarily, with groups of up to 300 individuals reported. May join mixed-species foraging flocks.

Breeding. Season mid-Mar to Jun in Europe and Japan (very exceptionally, fledged young recorded early Feb in England), from Mar onwards in Iran, and Mar–Apr in NE China; single-brooded. Co-operative breeding common; up to eight helpers recorded at single nest, these often adults from failed breeding attempts (male and female of failed pairs do not help at same nest, and, in cases where relationship established, helper is a sibling of male of breeding pair). In late winter or early spring flock breaks up, and unmated females move off to pair with males in adjacent flock. Display includes butterfly-like jerky flight, with presumed male flying up to height of 5–6 m above ground, alternately fanning and closing tail, then diving vertically down; 3–4 birds may display in quick succession or even simultaneously. Each pair sets up loosely defended territory within area occupied by male’s winter flock, but continues to roost with other flock-members until nest so far advanced that it can be used for roosting (usually when dome complete). Nest built by both sexes, over period of up to 33 days, a compact, domed, oval ball of moss, cobweb and hair, covered with up to c. 3000 flakes of lichen (which provide excellent camouflage), average size 160 mm high × 100 mm across, entrance hole at one side near top, lining composed of small feathers (often c. 1500, with maximum of 2680 recorded), adults may continue to add feathers during laying period; placed usually less than 3 m above ground in low thorny bush, but sizable minority sited 6–25 m up in tree fork or against trunk, or hanging among terminal twigs of conifer at up to 35 m above ground, and a few records of nests in hole in ground. Clutch 6–15 eggs, mostly 8–12, average clutch size largest at higher latitudes, eggs white, unmarked or with tiny reddish freckles, 14 × 10.9

mm (nominate race); incubation by female, fed on nest by male, period 12–18 days; chicks cared for by both sexes, assisted by variable number of helpers, presence of which significantly increases breeding success of pair; young leave nest after 14–18 days, fed by parents and helpers for at least a further 14 days, family-members then remaining together throughout winter.

Movements. Resident in temperate and Mediterranean regions, but partially migratory farther N. Birds from N Siberia undertake regular migration late Aug, returning in May, with some dispersal to N in autumn (when flocks of hundreds of individuals recorded in C Siberia), although bulk of movement in S direction; numbers in S Siberia swelled by immigrants in winter, when species may be numerous as far S as Zaysan depression, in NE Kazakhstan (migrants recorded also in R Ili valley). Some remain in N of range (or even farther N than breeding range). In NE China, an irregular migrant and winter visitor at Beidaihe (coastal Hebei), Sept–Feb, occurring in larger numbers during “irruptions”. White-headed birds (nominate race) occur in winter S of breeding range in China, Japan and irregularly S to extreme S Korea (Hong Kong records presumed to involve escapes from captivity). N populations also make irregular, sometimes large-scale irruptions in W, when large numbers may reach Finland, Baltic region and E Europe, and much smaller numbers appear in W Europe, such movements reaching peak in mid-Oct and at least some individuals returning to natal area in spring; birds from N & E sometimes penetrate farther W (e.g. flock of 200 white-headed birds in Netherlands in Dec 1971), but crossing of water avoided, thus nominate race very rarely recorded in Britain, and within British Is resident *rosaceus* only an irregular autumn wanderer to Is of Scilly, 1 of May. Outer Hebrides and Orkney, and very rarely to Shetland. Vagrant in Morocco (Apr 1967). Populations breeding in mountainous areas presumably undertake some altitudinal movement, spreading to adjacent foothills and plains in winter (e.g. in Hebei, in NE China).

Status and Conservation. Not globally threatened. Common to fairly common in W Europe and in Korea and Japan, but scarcer towards edge of range in N Scotland and W Ireland and more local and sometimes scarce in E Europe and Siberia, and rare in Kamchatka; in Iran, common in Caspian lowlands but rather scarce in Zagros Mts. Estimated European population more than 3,000,000 breeding pairs, of which c. 30% in Spain; highest recorded densities in Iberia, more than 5000 pairs/50-km square. No major changes in status apparent, although species has expanded N in Norway since c. 1970 and some expansion noted also in N Scotland; in contrast, marked decline in Sweden since 19th century, and similar decline in recent years in Finland, most probably a result of modern forestry practices and the replacement of old-growth habitats with commercial monocultures. Flocks require large winter territories (c. 20–24 ha), and habitat fragmentation and degradation can lead to local extinctions. Notably, very vulnerable to harsh winter weather, following which numbers may decline by up to 80%, can take several years to recover from these setbacks, perhaps owing to high loss of nests (sometimes over 50%) to predators. Success often low, e.g. fledging rate in various studies 16%–28%; main nest predators crows (Corvidae), weasels (*Mustela*) and snakes.

2. Silver-throated Tit

Aegithalos glaucogularis

French: Mésange à gorge argent **German:** Silberkehl-Schwanzmeise **Spanish:** Mito Gorjigris
Other common names: Silver-throated Bushtit

Taxonomy. *Orites (?) glaucogularis* F. Moore, 1855, Shanghai, China.

Often treated as conspecific with *A. caudatus*, but plumage is distinctive, and there are no reports of regular intergradation or hybridization with that species in NE China (apparent “intergrades” recorded as migrants in coastal Hebei, but origin and status of these unknown). Two subspecies recognized.

Subspecies and Distribution.

A. g. vinaceus (J. Verreaux, 1870) – C & NE China from E Qinghai and C Gansu E to C & SE Nei Mongol, S Liaoning, N Hebei and Shandong, and, in W, S to mountains of C Sichuan and NW Yunnan.

A. g. glaucogularis (F. Moore, 1855) – EC China in Yangtze valley from Hubei (possibly also lowlands of Sichuan), parts of S Shaanxi and Henan E to Jiangsu and N Zhejiang.

Descriptive notes. 13–16 cm, of which tail 6–10 cm; 6.5–9 g. A tiny, round-bodied passerine with short stubby bill and long, narrow tail. Nominant race has forehead buff, lateral crownstreaks glossy black, merging on forehead, central crownstreak and centre of nape pale buff with variable blackish streaking; upperparts medium to dark grey, narrow band of pink on rump, outer scapulars tipped blackish; tail blackish, outer feather mostly white on outer web, inner rectrices with grey fringes on outer webs; upperwing blackish-brown, lesser and median wing-coverts darker, greater coverts fringed black, tertials and secondaries

with slightly paler edgings; lores, cheek and ear-coverts pale drab grey obscurely streaked, chin, submoustachial stripe and side of neck off-white, throat sooty black with fine pale grey feather tips; breast pale drab grey to buffy grey, belly slightly paler and whiter, flanks, vent and undertail-coverts clean pale pink; iris hazel; bill and legs greyish-black. Sexes alike. Juvenile is similar to adult, but chin, throat and breast vinous-pink, contrasting with white submoustachial area and side of neck, remainder of underparts washed yellow-buff, also some pale edging on scapulars and upperwing-coverts. Race *vinaceus* differs from nominate in having side of head and throat slightly paler, underparts also slightly paler, breast less intensely washed buff, but often marked by gorget of marginally darker and browner streaks, tail longer. Voice. Calls include high-pitched, pure, quiet but penetrating “see-see-see” or “see-see-see-sit” and a louder, slurred “tsirrup”; similar to vocalizations of *A. caudatus*.

Habitat. Forest edge and scrub, primarily deciduous; recorded also from pine (*Pinus*) forest in Yunnan. In N of range breeds in lowlands and mountains, up to c. 1700 m in Shaanxi (Qin Ling Shan), 2925 m in Gansu and 3020 m in Qinghai; in S may be restricted to mountains, occurring at up to 2590 m in N Sichuan and at least 3050 m in Yunnan.

Food and Feeding. No specific information. Diet and behaviour probably as for *A. caudatus*.

Breeding. Season Mar–Apr in NE China. No other information.

Movements. Presumed largely sedentary, but some evidence of altitudinal movements (but still present at 2835–3050 m in Yunnan in Jan–Feb). Also some dispersal away from breeding areas, and in NE China occurs as irregular migrant at Beidaihe, in coastal Hebei, late Aug to at least Feb.

Status and Conservation. Not assessed. Widespread and fairly common, and thus considered not to be at any immediate risk. Extent of range of nominate race uncertain; possibly found in lowlands of Sichuan, but further study required. Status of race *vinaceus* in NW Shandong uncertain, and may be only a passage migrant.

Bibliography. Bangs (1932), Bangs & Peters (1928), Cheng Tsohsin (1987), Dickinson *et al.* (2006a), Eck & Martens (2006), Elchécopar & Hüe (1983), Harrap & Quinn (1996), Kleinschmidt *et al.* (1922), Liang Wei *et al.* (2000), Riley (1926, 1931), Vaurie (1959).

3. White-cheeked Tit

Aegithalos leucogenys

French: Mésange à joues blanches

Spanish: Mito Cariblanco

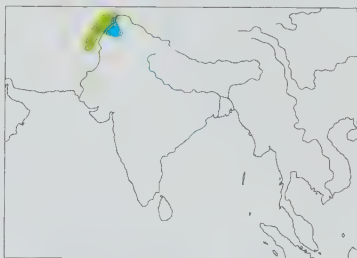

German: Weißwangen-Schwanzmeise

Other common names: White-cheeked Bushtit/Long-tailed Tit, Kashmir Tit

Taxonomy. *Orites leucogenys* F. Moore, 1854, Balu Chughur, Kunar River (near Jalalabad), eastern Afghanistan.

Affinities within genus not clear, although closest in overall appearance to *A. concinnus*. Monotypic.

Distribution. NE Afghanistan (Nuristan, S to Safed Koh), and N Pakistan from Chitral S to N Baluchistan (Shingar range and Ziarat), E to Gilgit, Baltistan, Hazara, Indus Kohistan (Palas Valley) and Margalla Hills near Islamabad.

Descriptive notes. 11 cm; 6–8 g. A typical long-tailed tit in shape, with medium-long tail, white cheek patch and blackish bib. Forehead and centre of crown are cinnamon-drab, washed olive-brown at rear; lores and narrow band backwards (barely encompassing eye) to side of nape black, poorly defined behind eye and grading to light greyish-drab on upper ear-coverts; cheek and lower ear-coverts white, extending onto side of neck as half-collar; upperparts and upperwing-coverts light greyish-olive; flight-feathers and tail medium to dark brown, remiges fringed paler (greyish-olive), outer two rectrices broadly tipped white;

chin and throat blackish, lower border tinged burgundy; upper breast light drab-grey, becoming duller and more ochre on lower breast and belly; flanks and vent pale pinkish-buff; iris straw-yellow or grey-yellow; bill black; legs pale orange-brown or pinkish-brown. Distinguished from *A. concinnus* mainly by duller crown, lack of white supercilium, narrower black band on side of head, black chin (bib therefore extending to bill), and paler and duller underparts; from *A. niveogularis* by dull forehead and forecrown and black bib. Sexes alike. Juvenile has crown slightly paler and more buffish, dark facial band slightly narrower, although better defined at rear, and upperparts slightly duller and browner, cheek patch and throat pale buff (thus lacks black bib, although may show hint of narrow dark bib on chin and centre of throat), side of breast dull cinnamon-brown, remainder of underparts pale pinkish-buff, variably streaked dark brown on upper breast. Voice. Contact call “si-si-si-si”, sometimes slightly slurred or lisping towards end (“si-si-si-si-sisip”); clipped, dry “tup” or “tep”, often interspersed with thinner “seeup” or “tsreet”; hard, explosive, slurred, rattling “trrrr” or “trrrp”. Also delivers a jumbled, rambling series of sweet, squeaky and warbling notes, but (as *A. caudatus*) probably lacks a true territorial song.

Habitat. Open dry scrubby forest of holly oak (*Quercus ilex*), juniper (*Juniperus*) and pine (*Pinus*), also almond (*Prunus dulcis*) scrub at higher altitudes; breeds at 1500–3660 m. In non-breeding season recorded at 500–2100 m, and may frequent edge of cultivation, thorn-scrub and riverine tamarisks (*Tamarix*).

Food and Feeding. Food insects and spiders (Araneae). Forages largely in shrub layer, also in crowns of holly oaks and well-grown junipers. Found in pairs; from late summer until about mid-Apr in parties of 6–12 individuals, often joining mixed-species foraging flocks.

Breeding. Season late Mar to May. Both sexes collect nest material; nest an upright oval ball c. 110 × 85 mm, entrance at side near top, woven from moss, grass, vegetable fibres and similar, bound with spider web and densely lined with feathers, 1–3.5 m above ground and usually placed in thorny bush, stunted holly oak or juniper. Clutch 5–8 eggs, white, sometimes faintly spotted pinkish-red at larger end, size c. 14.7 × 9.9 mm; no information on incubation and nestling periods; both sexes feed the fledged young, which remain dependent for at least 14 days after leaving nest.

Movements. Resident, with some seasonal altitudinal movement. Also some limited post-breeding dispersal; e.g. in Pakistan recorded from the Attock and Campbellpore region of NW Punjab.

Status and Conservation. Not globally threatened. Restricted-range species: present in Western Himalayas EBA. Common in Afghanistan; locally common in Pakistan, although rather scarcer in Gilgit. Recent reports of this species from S Himachal Pradesh, in N India, suggest some migratory movement or, more likely, an overlooked population; old reports of its occurrence in adjacent regions (Kashmir and Uttaranchal), however, unconfirmed and/or unreliable.

Bibliography. Ali & Ripley (1983), Dymond (2003), Eck & Martens (2006), Harrap & Quinn (1996), Paludan (1959), Raja *et al.* (1999), Rasmussen & Anderton (2005b), Roberts (1992), Stattersfield *et al.* (1998), Wunderlich (1989b).

4. Black-throated Tit

Aegithalos concinnus

French: Mésange à tête rousse

German: Schwarzkehl-Schwanzmeise

Spanish: Mito Gorjinegro

Other common names: Red-headed (Long-tailed) Tit, Black-throated Bushtit

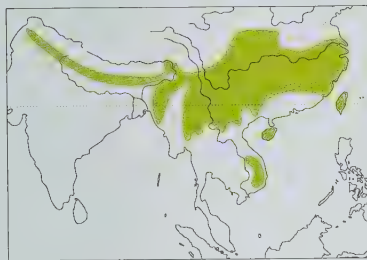

Taxonomy. *Psaltira concinna* Gould, 1855, Chusan, Zhejiang, eastern China.

Marked geographical variation, and very preliminary genetic studies suggest that this species may, in fact, represent an unresolved species swarm. Races divided into three groups, *iredalei* forming

one group, *annamensis* another, and remaining four races forming "n nominate group". Race *annamensis* is morphologically distinct, and its separation as a full species could well be justified on this basis alone. Some SE Asian populations of this species of uncertain racial affinity: thus, birds in NW Thailand presumed to belong with *pulchellus*, those in EC Laos (Nakay-Nam Theun) tentatively included with *talifuensis*, and those in NE Vietnam and on Hainan I presumed to be of nominate race. Race *talifuensis* perhaps better synonymized with nominate. Proposed race *taiwanensis* (Taiheisan, in Taiwan) inseparable from nominate. Six subspecies recognized.

Subspecies and Distribution.

A. c. iredalei (Stuart Baker, 1920) – N Pakistan (Swat) E in Himalayas to NE India (Mishmi Hills, in E Arunachal Pradesh), also SW China (Sun Kosi valley and Tsangpo bend area of S Xizang).
A. c. manipurensis (Hume, 1888) – NE India (from SE Arunachal Pradesh S to Lushai Hills of E Mizoram) and W Myanmar (Chin Hills).
A. c. talifuensis (Rippon, 1903) – NE Myanmar (E of R Irrawaddy), S China (C & SW Sichuan S from Emei Shan, S to Yunnan and SW Guizhou), N & EC Laos and NW Vietnam.
A. c. pulchellus (Rippon, 1900) – E Myanmar (S Shan States and Karenni District) and NW Thailand.
A. c. concinnus (Gould, 1855) – EC & SE China (S Shaanxi and Hubei E to S Jiangsu, S to N Guangxi and Fujian; has bred Hong Kong, but possibly birds of captive origin), also NE Vietnam (Cao Bang and Ha Giang Provinces), Hainan I and Taiwan.
A. c. annamensis (Robinson & Kloss, 1919) – S Laos (Boloven Plateau), Vietnam (C & S Annam) and adjacent Cambodia (Phumi Dak Dam).

Descriptive notes. 10–5 cm; 4–9 g. Small passerine with medium-long tail, white chin, black throat and black "bandit mask" around pale eye. Nominative race has crown cinnamon with slight rufous tinge, lores and broad band backwards through (and above and below) eye to side of nape black; upperparts blue-grey, rump tinged brownish-ochre; greater upwings coverts and flight-feathers dark brown, remiges broadly fringed grey; tail blackish-brown with grey edges to feathers, outer three pairs tipped white, outermost with white outer web; chin, submoustachial area and side of neck white, throat black, white band across lower throat,

below this a well-defined but fairly narrow cinnamon-rufous breastband (may be nearly broken in centre); flanks rufous-chestnut, remainder of underparts white (pale pinkish-buff feather bases on belly and vent visible when plumage worn); iris yellow-white; bill black; legs dull orange-brown or brownish-yellow. Sexes alike. Juvenile has cap slightly paler than adult, upperparts duller and browner, chin and throat off-white, variably prominent gorget of dark spots or streaks across uppermost breast, dull underparts washed buffish. Races differ mainly in plumage pattern and tone: *talifuensis* is similar to nominate but crown darker, some faint white flecks on rear side of crown, and breastband and flanks darker rufous-chestnut; *manipurensis* has crown more rufous-tinged cinnamon than nominate, a few white feather tips in superciliary area, and breast and flanks slightly paler rufous-cinnamon, also breastband somewhat broader and less well defined; *pulchellus* resembles previous, but forehead and crown light drab brown, no white (or just a few faint white flecks) in superciliary region, centre of lower breast and belly purer white; *iredalei* is distinctive, has forehead cinnamon-orange, crown and nape rufous, prominent white supercilium from above and behind eye to nape, white of chin, submoustachial area and side of neck tinged buff, narrow band on upper breast pale buffy white, grading to rufous-buff on breast and pinkish on flanks and side of vent; *annamensis* is also very distinctive, with forehead pale dull grey, centre of crown slightly darker, vague white-flecked supercilium from above eye back to nape side, whitish underparts with medium grey breastband and beige or light greyish-pink flanks. VOICE. Very vocal. Usual contact calls a high-pitched, sibilant "see-see-see"; fuller and flatter clipped "chet", usually interspersed with single high, sibilant "tset" or harsh "tsreet" notes; explosive, slurred, hard rattling trill falling in pitch towards end, "trrrret" (like short wind of a clockwork mechanism), which in agitation may be rather harsh and then taken up by every flock-member; short, full, squeaky "psiup"; delicate trilling "tsee-see-si-si'sisi", repeated every few seconds, reminiscent of song of Common Blue Tit (*Cyanistes caeruleus*).

Habitat. Primarily edge habitats in broadleaf forest, especially oak (*Quercus*), also mixed forest and sometimes cedar (*Cedrus*) and, especially in NE India (possibly also C Vietnam), pine (*Pinus*). In addition, found in wide variety of lightly wooded or bushy habitats, including rhododendron (*Rhododendron*) and bamboo. Generally at middle altitudes in subtropical and temperate zones. In Himalayas E to Myanmar and N parts of SE Asia breeds mostly at 1200–2700 m (1400–2500 m in W); in Vietnam found in N at c. 1000 m and in Annam at 600–1980 m, with breeding noted at 600 m, and in EC Laos at 1000–1800m; in China recorded at 75–3960 m (but probably breeds mainly 1500–2500 m), and in Taiwan recorded 1000–3000 m (probably breeds 1500–2400 m). During dispersal (apparently to both higher and lower elevations), recorded to 3000 m in W Himalayas and to 3600 m in E Himalayas, and down to 1200 m in Pakistan (900 m elsewhere in W Himalayas), 1065 m in Nepal, 400 m in Bhutan and NE India (Arunachal Pradesh) and 900 m Myanmar, but except in hardest weather does not usually descend below breeding zone.

Food and Feeding. Food insects; also small seeds and fruits, especially raspberries (*Rubus*). Forages mainly in middle and lower storeys. Very gregarious, and usually in flocks, sometimes containing as many as 40 individuals; small flocks found throughout breeding season (comprising failed breeders or non-breeders and, later, family parties from early broods). Often joins mixed-species foraging parties.

Breeding. Season relatively early, Mar–May (sometimes to Jun) in Himalayas, NE India and Myanmar, Apr in NW Thailand, and late Feb–May in China; single-brooded. Sometimes co-operative breeder, with helper. Nest built by both sexes, female taking dominant role, work over a protracted period, 10–11 days in C China (NE Sichuan), sometimes more than two weeks, an oval ball 100–150 mm tall × 95–140 mm wide, entrance hole at side near top, made from green moss, lichen, rootlets, bark scraps, hair, spider egg cases and vegetable down, bound together with spider webs, densely lined with feathers and sometimes also wool, fur or vegetable down; usually sited up to 3 m above ground in fork or woven around several twigs in low tree or bush, occasionally to 12 m up on horizontal bough of deodar (*Cedrus*) or at tip of a pine branch, rarely in rough grass or other low, tangled vegetation. Clutch 3–8 (generally 3–6) eggs in Himalayas, 3 in NE India and N Myanmar and 3–5 in W Myanmar (Chin Hills), white or pale pink, variably but usually finely spotted reddish, especially in a ring at larger end, occasionally unmarked, average size 13.9 × 10.6 mm; incubation by female or by both sexes (male roosts in nest), period c. 14–16 days; chicks fed by both sexes, duration of nestling period in C China 14 days; three nests in C China each had one helper present, latter assisting in both incubation of eggs and brood-feeding; young remain dependent on parents for at least ten days after fledging.

Movements. Mostly resident. Undertakes erratic and rather limited altitudinal movements. Sporadic presence in Hong Kong (where has bred), but these birds may be of captive origin.

Status and Conservation. Not globally threatened. Generally fairly common to common, and locally abundant; very rare on Mt Victoria (W Myanmar). Mean density of 1.4 breeding pairs/km has been recorded in Bhutan. Race *annamensis* recently recorded in E Cambodia, where presumed previously overlooked. Presence (race *manipurensis*) in Meghalaya and Cachar, in NE India, suspected, but confirmation required.

5. White-throated Tit

Aegithalos niveogularis

French: Mésange à gorge blanche **German:** Weißkehl-Schwanzmeise **Spanish:** Mito Gorjiblanco
Other common names: White-throated Bushit/Long-tailed Tit

Taxonomy. *Orites* (?) *niveogularis* F. Moore, 1855, northern Punjab, India.

Forms a superspecies with *A. iouschistos*, *A. bonvaloti* and *A. sharpei*; all four sometimes treated as conspecific, but they seem to be morphologically fairly distinct from one another and, while ranges overlap only minimally or not at all (e.g. range of present species does not quite meet that of *A. iouschistos* in C Nepal), there is no evidence of intergradation or hybridization between any of them. Monotypic.

Distribution. NE Pakistan (Palas and Kandia valleys, Kagan valley and Neelum valley) and Kashmir E to N India (Himachal Pradesh, N Uttarakhand Pradesh) and WC Nepal (E to Dolpo and NW flanks of Dhaulagiri massif, rarely to E flank of Kali Gandaki valley; single report from Gosainkund).

Descriptive notes. 11.5 cm; mean for three individuals 7.8 g. Typical long-tailed tit, with medium-long tail. Has forehead and broad crownstripe white, grading to cinnamon-brown on central hindcrown and nape; lores, cheek and side of crown black, becoming blackish-brown on rear crown and cinnamon-brown on rear ear-coverts, and merging into nape and upper mantle; upperparts light grey to medium grey (washed buffish when plumage fresh), narrow pinkish band on rump; greater upwings coverts and flight-feathers dark grey-brown, fringed light grey, tail dark grey-brown, feathers edged grey, outer three pairs tipped

white, outermost extensively white; chin and throat pale grey, submoustachial area and side of neck purer white, clearly demarcated from narrow cinnamon-brown breastband; remainder of underparts beige or pale pinkish-brown; iris pale brown to dark brown or reddish-brown; bill dark slate to black; legs flesh-yellow to brown. Differs from *A. leucogenys*, *A. concinnus* and *A. iouschistos* in white throat, half-collar, forehead and forecrown, and dark eye. Sexes alike. Juvenile has duller crownstripe, tinged buff on forecrown, browner upperparts, buff wash on side of neck and submoustachial, dull pinkish throat (sometimes mottled darker), and narrow, irregular and less contrasting breastband. VOICE. Calls include thin, high-pitched "tsi-tsi-tsi", soft clipped "pit", also a slurred high-pitched "tsreet", becoming in excitement a louder, hard, explosive descending rattle, "tsirrrrr". Apparent song a long and complicated series of phrases, not very loud or far-carrying, comprising rapid chattering "tweet-tweet" notes interspersed with rapid "tsi-tsi-tsi" phrases and short elided warbling phrases, more complex than (and superior to) equivalent vocalizations of *A. leucogenys* and *A. concinnus*; as *A. caudatus*, however, probably lacks a true territorial song.

Habitat. Scrub of barberry (*Berberis*), rose (*Rosa*), willow (*Salix*), rhododendron (*Rhododendron*) and the like, in and on margins of coniferous, mixed birch–spruce (*Betula–Picea*) and oak (*Quercus*) forest. In C Nepal breeds in drier trans-Himalayan zone, but in Pakistan found in moist coniferous forests and in N India (Kumaon) in oak forest. Breeds at high altitudes, towards tree-line, in Pakistan recorded at 2400–3400 m in spring, in Kashmir 2440 m to c. 3660 m (nests found at 2560 m), in Uttarakhand Pradesh at 2000–3700 m (nests at minimum of 3350 m, but recorded in summer also at 2000–2600 m) and in Nepal at 2750–3965 m; recorded in winter months at 1750–2200 m in Palas valley (Pakistan) and down to 1800 m in Kashmir.

Food and Feeding. Food largely insects, especially insect larvae and pupae, also spiders (Araneae); possibly also flower buds. Forages in shrub layer. Found in pairs in spring and early summer; otherwise usually in small parties, sometimes as many as 20 individuals together, and may join mixed-species foraging flocks.

Breeding. Carrying nest material on 24th May in Pakistan, and eggs recorded 26th Jun (possibly replacement clutch) and young in early to mid-Jun in N India (Uttarakhand); large young on 31st May in Kashmir. Nest an oval or pear-shaped ball of moss and cobwebs, covered with lichen and densely lined with feathers, entrance to one side near top, placed in fork 1–3 m above ground in tree or bush or suspended in tree branches up to 10 m up. One clutch of 4 eggs recorded (variation in clutch size unknown), eggs white, finely spotted pink at broader end, c. 14.2 × 11 mm. No other information.

Movements. Resident, with some seasonal altitudinal movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Western Himalayas EBA. Rare and local in Pakistan; uncommon to locally common in India; generally rare and local in Nepal, but locally common in Langu valley (W Nepal). Population density apparently low.

Bibliography. Ali & Ripley (1983), Dickinson *et al.* (2006a), Eck & Martens (2006), Fleming *et al.* (1984), Grimmett *et al.* (1998), Harrap & Quinn (1996), Inskipp & Inskipp (1991), Martens & Eck (1995), Raja *et al.* (1999), Rasmussen & Anderton (2005b), Roberts (1992), Stattersfield *et al.* (1998), Sultana & Khan (2000), Vaurie (1957a), Wunderlich (1989a).

6. Rufous-fronted Tit

Aegithalos iouschistos

French: Mésange de Blyth **German:** Rostwangen-Schwanzmeise **Spanish:** Mito Frentirrufo
Other common names: Rufous-fronted Bushit, Blyth's (Long-tailed)/Himalayan/Black-headed Tit

Taxonomy. *Parus iouschistos* Blyth, 1845, Nepal.

Forms a superspecies with *A. niveogularis*, *A. bonvaloti* and *A. sharpei*; all four sometimes treated as conspecific, but they seem to be morphologically fairly distinct from one another and, while ranges overlap only minimally or not at all (e.g. range of present species does not quite meet that of

A. niveogularis in C Nepal, and marginally sympatric with *A. bonvaloti* in SW China), there is no evidence of intergradation or hybridization between any of them. Monotypic.

Distribution. C & E Nepal E in narrow band along S flank of Himalayas to at least Bhutan, extending N of main range into SW China (SE Xizang E to the Yi'ong Zangbo and Po Tsangpo).

Descriptive notes. 11 cm; 6–7.5g. Typical long-tailed tit in size and shape, with well-graduated long tail. Has forehead and centre of nape cinnamon, broad crownstripe paler cinnamon-buff, side of crown glossy black, grading to black on lores and upper ear-coverts; lower ear-coverts, cheek and side of neck cinnamon-buff, narrow rufous submoustachial stripe extending to side of breast; upperparts dull mid-grey, slightly pinker on rump; greater upwings-coverts and flight-feathers dark grey-brown, fringed medium grey, tail dark grey-brown, outer three feather pairs tipped paler; chin and side of throat black (forming

diffuse inverted “V”), centre of throat and breast silvery grey, remainder of underparts rufous-cinnamon; iris yellow-white to lemon-yellow; bill black; legs yellow-brown or flesh-brown to dark brown. Differs from *A. concinnus* in having much more extensive blackish on side of head, pale crownstripe, lack of white supercilium and lack of black bib; from *A. niveogularis* in cinnamon-buff (not white) crownstripe, extensive blackish on side of head, small silvery bib, and cinnamon-rufous underparts lacking darker breastband. Sexes alike. Juvenile has crownstripe paler, side of head duller black, submoustachial stripe and ear-coverts pale pinkish-buff, side of neck and entire underside (including throat) dirty pale buff, more cinnamon-buff on belly and vent, with dark grey blotching and spotting, especially on breast. VOICE. Calls include high “si-si-si”, single thin, high-pitched, insect-like “tsit”, full clipped “chip”, squeaky “ip, ip...”, and explosive, slurred, rattling trill, “ttrrrp”; all may be given more or less simultaneously by flock-members during foraging.

Habitat. Forest edges, clearings and scrubby growth in and around temperate forest of oak (*Quercus*), rhododendron (*Rhododendron*) and chestnut (*Castanopsis*), also mixed forest and stands of pine (*Pinus*), spruce (*Picea*) or hemlock (*Tsuga*) at higher altitudes and scrub above tree-line, especially riverine scrub; in SW China (SE Xizang) habitat occupied varies from scrubby, almost desert-like slopes to dense forest. Altitudinal range in Himalayas 2200–3770 m, and in SW China at least 2745–3505 m; some post-breeding dispersal downwards into subtropical evergreen forest, but only occasionally moves lower in winter except during heavy snowfalls, when may descend a few hundred metres; in Sikkim recorded in winter at 2745–3720 m, exceptionally down to 2440 m in severe weather, and in Bhutan regular upper altitudinal limit in summer 3400 m but descends below 3200 m mid-Nov to mid-Mar. Seldom, if ever, overlaps altitudinally with *A. concinnus*.

Food and Feeding. Food insects, including their eggs and larvae; also some vegetable matter. Forages in canopy, as well as in shrub layer. Occurs in parties of up to 40 individuals outside breeding season, sometimes joining mixed-species foraging flocks (but found in single-species flocks more frequently than are congeners).

Breeding. Flock breaks up into pairs Mar–Jul; noted as carrying nest material on 7th Apr and 4th May, female with oviduct egg on 24th May in Bhutan, young recorded in May and early Jun; nest-building in SW China 25th May. A nest in Nepal described as a ball, entrance hole to side, studded outside with lichens and lined with feathers, placed in oak tree; other nests have been recorded high in a fir tree (*Abies*) and near tip of a pine branch. Young in Nepal nest fed by both sexes. Gathers again into large flocks as soon as young able to fly. No other information.

Movements. Resident, with some limited seasonal altitudinal movement. Occasionally descends lower in winter, usually when heavy snowfall.

Status and Conservation. Not assessed. Frequent in Nepal, and fairly common to common in E Himalayas; extremely abundant in China (SE Xizang), and apparently commoner in drier areas N of main range of Himalayas than in denser forest to S. In Nepal, regular W to Langtang valley, rarely to Kali Gandaki valley and Dhaulagiri Massif (record farthest W in Dhorpatan); recorded very rarely in Kathmandu valley. Status in NE India uncertain: present in Darjeeling District, but possible distribution in Arunachal Pradesh requires clarification.

Bibliography. Ali & Ripley (1983), Cheng Tsohsin (1987), Dickinson *et al.* (2006a), Eck & Martens (2006), Fleming *et al.* (1984), Grimmer *et al.* (1998), Harrap & Quinn (1996), Inskipp & Inskipp (1991), Li Guiyuan *et al.* (1982), Ludlow & Kinneir (1944), Martens & Eck (1995), Rasmussen & Anderton (2005b), Spiereburg (2005), Vaurie (1957a), Wunderlich (1991a, 1991b), Zheng Zuoxin *et al.* (1983).

7. Black-browed Tit

Aegithalos bonvaloti

French: Mésange de Bonvalot **German:** Brauenschwanzmeise **Spanish:** Mito Cejinegro
Other common names: Black-headed/Bonvalot's Tit

Taxonomy. *Acredula Bonvaloti* Oustalet, 1892, Tatsienlu (= Kangding), Sichuan, China.

Forms a superspecies with *A. niveogularis*, *A. iouschistos* and *A. sharpei*; all four sometimes treated as conspecific, but they seem to be morphologically fairly distinct from one another and, while ranges overlap only minimally or not at all (e.g. range of present species meets or very marginally overlaps with that of *A. iouschistos* in SW China), there is no evidence of intergradation or hybridization between any of them. Races presumed to intergrade. Two subspecies recognized.

Subspecies and Distribution.

A. b. obscuratus (Mayr, 1940) – NC Sichuan (mountains NW of Red Basin, in region of Wenchuan), in C China.

A. b. bonvaloti (Oustalet, 1892) – SC China (W & C Sichuan S to SE Xizang, NW Yunnan and Weining region of W Guizhou) and extreme NE Myanmar (E of R Irrawaddy, S to Myitkyina).

Descriptive notes. 11 cm; 5–8.5 g. Typical long-tailed tit in size and shape, with well-graduated long tail. Nominant race has forehead whitish, crownstripe and centre of nape buffish, side of crown glossy black, grading to sooty black, on lores and upper ear-coverts; lower ear-coverts cinnamon-buff (well demarcated from dark colour above), submoustachial stripe off-white, sides of neck buffish; upper mantle dull cinnamon, remainder of upperparts dull mid-grey, slightly pinker on rump; greater upwings-coverts and flight-feathers dark grey-brown, fringed mid-grey, tail dark grey-brown, outer three feather pairs tipped white; chin and malar stripe sooty black (forming well-defined inverted “V”), centre of throat off-white (sooty black feather centres largely concealed), lower throat and upper breast white; side of breast, upper flanks and band across lower breast cinnamon, belly off-white, grading into pinkish or pinkish-cinnamon on lower flanks and vent; iris pale yellow to yellow-white; bill black; legs yellow-brown to dark brown. Differs from *A. concinnus* in having much more extensive blackish on side of head, narrower and paler crownstripe, and no black bib; from *A. fuliginosus* in blackish mask, inverted dark “V” on throat, and cinnamon

cheek patch. Sexes alike. Juvenile has side of head and markings on throat duller black, no cinnamon on upper border of mantle, paler and buffier ear-coverts contrasting less with submoustachial, throat and breast (which are washed buff), also underparts buff, spotted grey, especially on upper breast and centre of belly, forming irregular breastband of dark blotches. Races differ minimally: *obscuratus* is slightly duller and browner than nominate. VOICE. No specific information; vocalizations probably similar to those of congeners.

Habitat. Undergrowth and scrub in and around mixed forest, perhaps especially stands of willows (*Salix*) and poplars (*Populus*) along watercourses; less commonly in pines (*Pinus*) and subalpine forests of hemlock (*Tsuga*) and other conifers. In China recorded at c. 1500–4400 m (optimum zone probably 1500–3500 m), and in N Myanmar recorded from 1830 m to above 3100 m (not uncommon above 2135 m; some descend in winter to c. 1300 m, exceptionally to 700 m in subtropical evergreen forest (but observed above 3000 m in late Jan in Myanmar).

Food and Feeding. No information on diet. In non-breeding season forms foraging flocks.

Breeding. Recorded in May in S China (Guizhou); males coming into breeding condition in mid-Mar in N Myanmar. Nest c. 93 mm tall × 74 mm deep, external diameter 93 mm, entrance hole to side, a lichen-covered ball of moss and creepers, lined with feathers. Clutch 4–5 eggs, white, 14.4 × 10.6 mm; both sexes incubate eggs and feed young. No further information.

Movements. Resident; some seasonal altitudinal movements recorded.

Status and Conservation. Not assessed. Rather poorly known species. Sometimes considered uncommon in China, but reported as very common in SW Sichuan; common in NE Myanmar. Status in Kunming (Yunnan) uncertain, but perhaps only a non-breeding visitor.

Bibliography. Anon. (1980c), Cheng Tsohsin (1987), Eck & Martens (2006), Étiéhecopar & Hue (1983), Harrap & Quinn (1996), King (1989a), Li Guiyuan *et al.* (1976), Riley (1931), Rothschild (1921), Schäfer & Meyer de Schauensee (1938), Smythies (1986), Thayer & Bangs (1912), Vaurie (1957a), Wu Zhikang *et al.* (1986), Wunderlich (1991a, 1991b), Zheng Zuoxin *et al.* (1983).

8. Burmese Tit

Aegithalos sharpei

French: Mésange de Sharpe **German:** Burmaschwanzmeise **Spanish:** Mito Birmano
Other common names: Myanmar Tit

Taxonomy. *Aegithaliscus sharpei* Rippon, 1904, Mount Victoria, southern Chin Hills, Myanmar. Forms a superspecies with *A. niveogularis*, *A. iouschistos* and *A. bonvaloti*; all four sometimes treated as conspecific, but they seem to be morphologically fairly distinct from one another and, while ranges overlap only minimally or not at all, there is no evidence of intergradation or hybridization between any of them. Present species usually treated as conspecific with *A. bonvaloti* (sometimes with both *A. bonvaloti* and *A. iouschistos* when these are combined), but distinctive appearance (closer to that of *A. niveogularis*) and geographically remote distribution justify its treatment as a distinct species. Monotypic.

Distribution. Mt Victoria and Mindat, in S Chin Hills of SW Myanmar.

Descriptive notes. 11 cm. A typical long-tailed tit in size and shape, with well-graduated tail. Forehead and centre of crown are whitish, grading to cinnamon-brown on rear crown and nape; side of crown, lores and cheek black (black bands on side of head relatively narrow, especially at rear), ear-coverts cinnamon-brown; upper mantle cinnamon-brown, remainder of upperparts dull medium grey, slightly pinker on rump; greater upwings-coverts and flight-feathers dark grey-brown, fringed mid-grey, tail dark grey-brown, outer three feather pairs tipped white; chin and side of throat blackish (forming dull, relatively poorly defined inverted “V”), centre of throat, submoustachial area, side of neck and upper breast white, well-defined cinnamon-brown breastband; centre of lower breast and belly dirty pinkish-cinnamon, remainder of underparts cinnamon or cinnamon-buff; iris yellow; bill dark; no information on leg colour, probably brownish-horn. Differs from *A. concinnus* (of local race *manipurensis*) in having more extensive black on side of head, narrower crownstripe, whitish throat, and duller and browner breastband. Sexes alike. Juvenile undescribed. VOICE. Calls include thin, high-pitched “tsi-si-si-si”, more rolling “tscep”, soft “tsup”, and slurred, hard rattling “tsirrup”.

Habitat. More or less open forest of pines (*Pinus*) at 2500–3000 m (pine forest occupies drier slopes at these altitudes), and above this in open evergreen moss forest of oak (*Quercus*) and rhododendron (*Rhododendron*) up to the summit at 3053 m. Recorded in winter down to 2100 m.

Food and Feeding. No information. Behaviour reminiscent of that of *A. caudatus*.

Breeding. Adult carrying nest material on 3rd Apr, mating on 13th Apr and fledged young seen in May; male with enlarged testes in mid-Apr and two females with enlarged ovaries in late Apr. No other information.

Movements. Resident, with some seasonal altitudinal movement.

Status and Conservation. Not assessed. Poorly known; apparently not common, as some recent visitors to Mt Victoria have had difficulty in finding this species. Forest on Mt Victoria has been almost completely cleared below 2000 m and is degraded up to 2500 m; although the mountain lies within Natmataung National Park, forest destruction, especially by fires, is a continuing problem. Although this species has no conservation designation (as hitherto treated as conspecific with *A. iouschistos*), White-browed Nuthatch (*Sitta victorae*), similarly confined to forests of S Chin Hills, is classified as Endangered.

Bibliography. Eck & Martens (2006), Harrap & Quinn (1996), Rasmussen & Anderton (2005b), Robson (2000b), Robson *et al.* (1998), Stresemann & Heinrich (1940a).

9. Sooty Tit

Aegithalos fuliginosus

French: Mésange à col blanc **German:** Rußschwanzmeise **Spanish:** Mito Cuelliblanco

Food and Feeding. Bulk of food consists of small insects and spiders (Araneae); also small amounts of vegetable matter, including small galls (probably for the contents), olives (*Olea*), and tiny seeds such as those of willow (*Salix*). In study in California, scale insects (Coccidae) were most abundant food item taken (19%), but lepidopteran larvae may be far more important in terms of biomass. May be entirely carnivorous in summer. Gregarious, in flocks of up to c. 40 individuals during most of year, flock's foraging home range c. 100 ha, adults retain membership of same flock from year to year; may participate in mixed-species foraging flocks throughout year. Very agile and active, forages among thinner branches, slender stems and leaf stalks, mostly in outer portion of

tree or bush, even finest peripheral branches, but rarely on ground. Foliage-gleaning specialist. Frequently hangs upside-down (in manner of *Poecile* and *Parus* tits), and regularly uses a foot to bend back leaves in order to expose central portion of a clump of foliage. Usually simply swallows food items, but larger caterpillars (more than 1 cm long) repeatedly beaten on a branch; very rarely, holds prey in one foot (with tarsus resting on a branch) and tears it with bill before eating.

Breeding. Throughout range most clutches started in Apr, with extremes late Feb and mid-Jul, annual variations due to weather probably outweighing geographical variation; normally double-brooded (although rarely so in coastal California). Social system complex and not fully understood, also varies considerably both geographically and from year to year; breeding individuals continue to associate with all members of flock and roam freely through flock's foraging home range, although nests of all flock-members lie within smaller "nesting home range"; pairs within flock establish weakly defended, non-exclusive areas around nest during early part of breeding season, but do not defend this area after eggs laid (other flock-members may enter nest or steal nesting material). In some areas (e.g. SE Arizona), c. 30–35% of nests involve co-operative breeding, pairs showing high tolerance of conspecifics and allowing them to take part in lining of nest, incubation of eggs and feeding of young, and sometimes even to roost in nest (occasionally, one or both of pair are driven from an active nest by others); these helpers (often known as "supernumeraries") can be male or female, juvenile or adult, although majority are adult males that either are unmated or have lost a nest; in others regions (e.g. coastal California), co-operative breeding rare. Paired male and female determine nest-site by attaching and reattaching spider web in various places until enough has accumulated in one place; nest built by both sexes, taking 13–51 days (period depending on degree of reuse of material from failed nests), gourd-shaped, 165–300 mm tall × 65–100 mm in diameter, small circular entrance hole usually at one side near top, constructed from twigs, rootlets, moss, lichen, leaves, plant down, cocoons, grass, wool, feathers and flowers, all bound together with spider webs, interior lined with plant down, hair and feathers, placed 1–30 m above ground in tree or shrub, suspended from end of single twig or branch or woven around and supported by several twigs, and ranging from being completely hidden (e.g. in thick upper branches of a pine) to being completely exposed (oaks used in Arizona lose their leaves early in breeding season); if disturbed during nest-building, egg-laying or incubation, often deserts and builds new nest (pair may make up to five nesting attempts in a single season), old nests often dismantled and recycled in same season by same pair or by other pairs, allowing later nests to be constructed more rapidly than initial nests. Clutch 4–8 eggs (clutches of 9–15 eggs presumed result of more than one female laying in same nest), probably some geographical variation in clutch size, with smaller clutches commoner in S of range, eggs white, c. 13.7 × 10 mm; incubation by both sexes, period 12–13 days (15–16 days recorded in Guatemala), sometimes assisted by helpers if present; both parents and any helpers brood and feed young, which fledge after 18 days (will leave nest earlier, from 14 days, if nest disturbed), and all continue to add material until young leave nest; fledglings fed by parents and any helpers for at least 2 weeks; second clutch laid in same nest a few days after first brood leaves, even though these fledglings still dependent (occasionally, a new clutch laid in nest before first brood fledges).

Movements. Mainly resident, but some altitudinal movements. Birds of SW mountains move to higher altitudes in late summer or disperse in period Jul–Apr into suitable habitat in surrounding desert lowlands, e.g. to E watershed of Sierra Nevada (in California), to Colorado valley (in SW Arizona) and into N Sonora (Mexico) and W Texas (including N Texan Panhandle). In addition, some post-breeding wanderings, e.g. to SE Wyoming, and N & E in Colorado to Larimer County, and in Kansas several autumn–winter records from Morton County and recorded also in counties Ellis and Hamilton. Vagrant on Anacapa I, in SW California (Aug 1976).

Status and Conservation. Not globally threatened. Fairly common in small range in Canada; in USA, commonest in W coast states and in SW, fairly common in Nevada, Utah, Oklahoma and Texas, and uncommon in Idaho, Wyoming and Colorado; in Mexico, apparently commonest in N, in Baja California and Sonora, and rather sparser in S (although fairly common in Oaxaca); common in Guatemala. Population densities difficult to assess because of occurrence of widely ranging flocks and pairs. Probably vulnerable to exceptionally cold or wet winter weather. Has disappeared from some areas, e.g. in California from Santa Catalina I and the more cultivated portions of San Joaquin Valley (but may be recolonizing some areas where exotic vegetation has replaced native shrubs). Otherwise, range slowly expanding N & W in Oregon, N Washington and British Columbia. In British Columbia probably confined to R Fraser delta and nearby towns until mid-1930s, but has since spread to SE Vancouver I (where first confirmed breeding in 1937, at Victoria) and to gulf islands and throughout Fraser Lowlands, this linked to milder winters and probably also to habitat creation following forest clearance. Similarly, in Washington, originally found only in coastal areas around Puget Sound, but has expanded range inland and to some islands in Puget Sound as conifer forests of region have been replaced by suburban residential areas and shrubby second growth.

Genus *PSALTRIA* Temminck, 1836

11. Pygmy Tit

Psaltria exilis

French: Mésange pygmée **German:** Zwergschwanzmeise **Spanish:** Mito Pigmeo
Other common names: Pygmy Bushtit

Taxonomy. *Psaltria exilis* Temminck, 1836, Java. Relationship with other members of family obscure. Nevertheless, behaviour and vocalizations are very similar to those of the Palearctic species, such as *Aegithalos caudatus*. Monotypic.

Distribution. Mountains of W & C Java.
Descriptive notes. 8.5–8.7 cm. A tiny, long-tailed, nondescript aegithalid with short, stubby, broad-based bill. Head is drab greyish-brown, tinged cinnamon on forehead; upperparts, including upperwing, medium grey with brownish tinge, rump purer grey; tail dull grey-brown; chin and throat light grey, mottled and bordered below with pale pinkish-buff; side of breast, upper flanks and faint narrow breastband dull greyish-brown, rest of underparts very pale dull pinkish-buff; iris yellowish-white to whitish, sometimes brown or grey (perhaps age-related); bill greyish-horn, dark brown or black; legs flesh-yellow or yellow. Sexes alike. Juvenile remains undescribed, but thought to be very similar to adult. **Voice.** Calls include thin but penetrating, high-pitched "tsi-tsi-tsi-si-

si-si" (slowing and falling in intensity), fuller clipped "chut" and abrupt rattled "trrrt". Strongly reminiscent of voice of genus *Aegithalos*.

Habitat. Montane forest and plantations above 1000 m, occasionally down to 830 m; frequents conifers and other open trees, often on forest edge.

Food and Feeding. Food insects, including aphids (Aphidoidea) and caterpillars, also small spiders (Araneae). Active, travelling in small flocks. Often forages at low levels.

Breeding. Season Mar–May and Aug–Nov. Nest a suspended pouch of leaves and grass,

8–17 cm tall and 6–8.5 cm in diameter, lined with moss, small entrance hole (2–3 cm) near top, internal nest-chamber 3–5.5 cm deep, generally similar to nest of flowerpeckers (Dicaeidae), suspended 3–8 m above ground, concealed in foliage. Clutch 2–3 eggs, white with fine red spots, dimensions 11.8–13.4 × 9.3–10.6 mm. No other information.

Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Java and Bali Forests EBA. Locally common, e.g. at Cibodas. Records from Gonoarjo (near Mt Unguran) and above Pancoran Tujuh (Mt Slamet) may be the farthest E for the species. On densely populated island of Java, even this species of montane forest should be considered potentially at long-term risk from deforestation. Occurs in Gunung Gede-Pangrango National Park (Cibodas Biosphere Reserve)

Bibliography. Gould (1855), Harrap & Quinn (1996), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1948, 1949, 1950), Kuroda (1933a), MacKinnon (1988), Robson (1994b), Stattersfield *et al.* (1998), Vorderman (1886).

Genus *LEPTOPOECILE* Severtsov, 1873

12. Crested Tit-warbler

Leptopoecile elegans

French: Mésange mitrée **German:** Schopfhähnchen **Spanish:** Carbonerito Elegante

Taxonomy. *Leptopoecile elegans* Przevalski, 1887, upper Huang Ho, south-east Qinghai, China. Relationships of genus uncertain; formerly placed in family Sylviidae, and recent studies based on mitochondrial DNA indicate that it groups with members of present family within a sylvidium assemblage that includes tits and chickadees (Paridae). Further research required. Birds from Malashi country, S of Litang (SE Xizang–W Sichuan), described as race *meissneri*, but probably inseparable from those elsewhere in species' range. Treated as monotypic.

Distribution. C & E Qinghai, S Nei Mongol (Alashan and Helan Shan), Ningxia (Helan Shan) and S Gansu (S Qilian Shan) S to SE Xizang and W & C Sichuan, in C China.

Descriptive notes. 10 cm; one male 8 g. Tiny, crested passerine with relatively long, graduated tail; male exquisite in coloration. Male has forehead greyish-white, crown pale ash-grey, feathers of rear crown elongated to form short, pointed, silky white-tipped crest (usually held flattened to nape); nape, sides of neck and sides of breast, as well as cheeks and ear-coverts, rich rufous, mantle and back blue-black or indigo, scapulars olive-grey, feathers of lower back, rump and uppertail-coverts broadly tipped turquoise; tail dark grey, feathers fringed iridescent dark turquoise; upperwing-coverts and flight-feathers drab olive-brown, outer

greater coverts diffusely fringed dull pale blue, primaries P3–P10, secondaries and tertials fringed iridescent sky-blue at base (inwards of emarginations on primaries); base of bill and lores blackish, chin and throat rufous-cinnamon, breast and undertail-coverts cinnamon, belly and vent pale buff, flanks (especially lower flanks) extensively washed dark mauve; in worn plumage paler and less intensely coloured, especially on underparts; iris ruby-red; bill black; legs brown, toes dark brown. Female is much duller than male, forehead and very narrow supercilium in front of eye dirty buff-white, crown and nape medium to dark grey with dull lilac wash, feathers of rear crown elongated into short whitish-tipped crest; lores and eyestripe blackish-grey, extending broadly onto and around nape; mantle cinnamon-brown, scapulars more cinnamon-buff, back medium to dark grey, washed dull slate-blue, rump sky-blue, uppertail-coverts buffy; tail dark drab brown, feathers finely fringed dull blue; upperwing-coverts and flight-feathers dark drab brown, outer greater coverts and primary coverts finely fringed dull blue, primaries P3–P10, secondaries and tertials finely fringed iridescent sky-blue (as male); cheek, ear-coverts, lower side of neck, throat and breast off-white to pale grey, lightly washed buff, lower belly, rear flanks, vent and thighs drab brown, lightly washed lilac, undertail-coverts cinnamon; bare parts as male. Juvenile male is like female, but crest longer and with pale feather tips broader and whiter, wing and tail feathers slightly paler, sky-blue of rump duller and more restricted, cheek, ear-coverts, throat and breast cleaner and whiter, flanks more distinctly lilac, iris dull olive-brown or red; juvenile female even duller. **Voice.** Calls include very thin, plaintive, descending "psee", similar to call of *L. sophiae*, and softish "dep", also a shrill single note similar to contact call of Northern Wren (*Troglodytes troglodytes*); other calls reminiscent of those of Goldcrest (*Regulus regulus*).

Habitat. Conifer forest, especially spruce (*Picea*), outside breeding season sometimes found in scrub, such as juniper (*Juniperus*) and rhododendron (*Rhododendron*) scrub. In summer occurs at c. 3400–4300 m, descending in winter to 2600–3900 m.

Food and Feeding. Food insects. Forages high in trees in manner of kinglets and firecrests (*Regulus*), and frequently along small branches in manner of a nuthatch (*Sitta*). In non-breeding season, not uncommonly joins mixed-species foraging flocks, which can include *L. sophiae*, Goldcrest and Willow Tit (*Poecile montanus*), and may forage in scrub.

Breeding. Very poorly known. A nest seen c. 15 m up in a conifer; once both partners observed in late Apr while collecting nest material, including feathers of Blue Eared-pheasant (*Crossoptilon auritum*), probably for lining of nest. No other information.

Movements. Poorly known. Usually presumed to be resident, but possible that the populations in extreme N of range largely migratory. Undertakes some seasonal altitudinal movements.

Status and Conservation. Not globally threatened. Generally rather uncommon. Possible occurrence in extreme NW India (NW Arunachal Pradesh) requires investigation.

Bibliography. Baker (1997), Bangs & Peters (1928), Cheng Tsohsin (1987), Deditius (1887), Hartert (1907a), Ludlow & Kinnear (1944), Pleske (1890), Rasmussen & Anderton (2005b), Sturmhuber *et al.* (1998), Vaurie (1957d, 1959), Zheng Zuoxin *et al.* (1983).

13. White-browed Tit-warbler

Leptopoecile sophiae

French: Mésange de Sophie **German:** Purpurhähnchen **Spanish:** Carbonerito de Sophie
Other common names: Severtsov's Tit-warbler; Stoliczka's Tit-warbler ("stoliczkae group")

Taxonomy. *Leptopoecile Sophiae* Severtsov, 1873, Lake Issyk-Kul', Tien Shan, Kyrgyzstan. Relationships of genus uncertain; formerly placed in family Sylviidae, and recent studies based on mitochondrial DNA indicate that it groups with members of present family within a sylvioid assemblage that includes tits and chickadees (Paridae). Further research required. Precise geographical boundaries of races not well known, and review needed. Races divisible into two groups, one with relatively dark plumage (nominate and *obscurus*) and the other pale (*major* and *stoliczkae*); combined ranges of dark races form a ring that almost entirely encircles those of pale races, and has been suggested that groups are separated ecologically, with darker "nominate group" at higher elevations in relatively moist subalpine scrub and adjoining forest and paler "*stoliczkae* group" confined to well-wooded arid montane terrain at lower altitudes (at least where the groups overlap); if this ecological separation were confirmed, the two groups would be best treated as separate species. Nominant race intergrades with *obscurus* in the NE Qinghai and adjacent Gansu region of C China. Four subspecies recognized.

Subspecies and Distribution.
L. s. sophiae Severtsov, 1873 – mountains in SE Kazakhstan, Kyrgyzstan and Tajikistan, NW China (W Xinjiang, N Gansu, E Qinghai) and, in S, N Pakistan (S to Baltistan) and NW India (Ladakh).
L. s. obscurus Przevalski, 1887 – S & E fringes of Tibetan Plateau from trans-Himalayan region of C Nepal (Dolpo), S & SE Xizang (Lhasa, Tsangpo Bend area) and S & E Qinghai E to S Gansu and NW Sichuan (S to Kangding).
L. s. major Menzbier, 1885 – W China in W Xinjiang (upper Tarim) and N Qinghai.
L. s. stoliczkae (Hume, 1874) – W China in S Xinjiang, W Qinghai and extreme W Xizang (upper R Indus).

Descriptive notes. 8.5–10 cm; 6–8 g. Tiny passerine with relatively long, graduated tail, males startlingly coloured, with patches of violet-blue and mauve. Male nominate race has lower forehead and broad supercilium pale buffy white (whitest immediately above eye), well defined on lower border but slightly ragged on side of crown; crown rufous with lilac-washed medium grey feather tips (partly obscuring ground colour), nape, side of neck, mantle, upper back and scapulars light drab grey, washed violet-blue on side of neck; rump and uppertail-coverts violet-blue, rufous feather bases (fully concealed); tail blackish,

outer webs of outermost feather off-white, outer webs of remaining rectrices diffusely fringed slate-blue at base; upperwing-coverts and flight-feathers dark brownish-grey, narrowly fringed slightly paler, fringes more cinnamon-buff on tertials, and a little paler and better defined with slight blue cast on basal half of primaries; lores and short eyestripe medium grey to dark grey, cheek and ear-coverts tinged medium grey (rufous feather bases concealed); chin and throat rufous, feathers tipped greyish (as crown), feathers of lateral and lower parts of throat broadly tipped violet-blue (together with sides of neck forming diffuse blue collar); side of breast and flanks rufous or vinous, feathers with broad mauve subterminal area and finer violet-blue tips (latter especially vivid and extensive on lower flanks and side of belly), centre of lower breast and belly dull white, washed buff, undertail-coverts rufous, thighs dull cinnamon-buff; iris reddish; bill black; legs brownish-black to black. Female is much duller than male, broad light brownish-grey supercilia meeting on forehead (palest and purest immediately over and behind eye), crown dull cinnamon-brown, upperparts and wing as male, rump and uppertail-coverts with narrower and less richly coloured mauve tips (not fully concealing rufous bases); lores and short eyestripe medium grey, cheek and ear-coverts mottled light greyish-brown, underparts pale brownish-grey with rufous area restricted to lower flanks, where feathers tipped mauve; thighs and undertail-coverts greyish-buff; iris reddish-brown. Juvenile is very like adult but plumage slightly softer and duller, male as adult female but crown brighter and more rufous (lacking lilac-grey tips, thus more vivid than adult male), rump and uppertail-coverts cinnamon with more restricted and less conspicuous mauve tips, pale fringes on outer rectrices duller and more restricted, underparts duller and greyer, washed mauve on throat and with more extensive cinnamon on side of breast and flanks, where feathers tipped mauve, bill paler; juvenile female similar, but rump cinnamon-brownish without mauve or lilac, underparts dull buff-washed white, with very restricted cinnamon-brown on flanks and no lilac or mauve tones, iris probably dull olive-brown (confirmation required). Races differ mainly in tone of plumage: *obscurus* is overall rather darker than nominate, male crown more rufous (greyish feather tips reduced, cap more clearly defined at rear), upperparts and face darker, medium to dark grey, rump more intensely violet-blue, supercilium shorter and narrower, throat and side of neck darker and more purplish-blue, underparts much darker and more uniformly dark mauve (feathers rufous with broad mauve tips, giving slightly mottled effect), thighs dark grey; *major* is distinctly paler and duller than nominate, buff of underparts paler and more extensive, reaching on to upper breast; *stoliczkae* is even paler than previous, buff of underparts extending to base of throat. Voice. Contact call a sibilant, trilling "sirrrrr" (or "tszirr-tszirrpsirrr"), by both sexes throughout year, function depending on intonation and delivery rate (when given calmly, with long pauses, is usual contact between members of pair or flock; when louder, lower-pitched and with slightly faster delivery, serves as warning call; coarser variant with very fast delivery rate expresses alarm). Other

calls include thin, plaintive (almost hissing) "psee" or more drawn-out "pseee", not unlike that of Western Penduline-tit (*Remiz pendulinus*), also short, full, abrupt, slightly rough or buzzing "psrit" (or "zip"), often paired or repeated in irregular series, e.g. "psrit-psrit, psrit-psrit-psrit, psrit...", and delivered both in flight and at rest; juvenile gives thin "si-si". No territorial song, but male occasionally gives quiet and subdued but vigorous murmuring and melodious whispering, mixed with similarly quiet (mechanical) creaking sound; this "song" given in later stages of nest-building and in laying period during courtship, when sexes meet and prior to copulation.

Habitat. Montane forest, scrub and thickets. In Kazakhstan, breeds from upper margins of spruce (*Picea schrenkiana*) forest zone to upper limit of juniper (*Juniperus*) scrub at c. 2200–3200 m, but optimally in fairly narrow altitudinal band where juniper scrub best developed (c. 2500–2900 m); scrub mainly prostrate form of *Juniperus turkestanica*, in scattered clumps on steep (up to 45°) slopes, or (mainly on S-facing slopes) in impenetrable thickets. In non-breeding season found below spruce zone and into foothills, where frequents thickets of rose (*Rosa*), *Prunus*, *Elaeagnus* and willow (*Salix*) and occasionally tall herbaceous vegetation, often on S-facing slopes and in scrub by water; sporadically in gardens, parks and roadside trees. In W Tien Shan, winters in thickets of sea-buckthorn (*Hippophae rhamnoides*), *Elaeagnus*, tamarisk (*Tamarix*) and *Ephedrum* in river valleys, sometimes (when much snow in valleys) on plains at 400–450 m. Elsewhere in range, breeds in dwarf scrub (perhaps especially *Juniperus*, *Berberis* and *Caragana*) above tree-line in dry mountainous areas (e.g. in Himalayas found in more arid, rain-shadow regions and may have preference for drier S-facing slopes). In N Indian Subcontinent breeds at 3000–3900 m in Pakistan and India and recorded at 2700–4575 m (probably breeding mostly above 3500 m) in Nepal; in winter down to c. 1800 m (seldom lower), and favouring, where available, valley-bottom thickets (especially *Hippophae rhamnoides*, *Astragalus* and *Phragmites*). In China recorded at 2700–5000 m, in Nan Shan (Gansu) common throughout subalpine belt at 3000–3600 m from upper limit of forest through *Caragana jubata* zone to uppermost juniper scrub; in Xining region (Qinghai) breeds down to 2700–2600 m, where *Berberis* predominant; in Xizang found at 3500–5000 m.

Food and Feeding. Diet small insects and spiders (Araneae); also, mainly in autumn and winter, small quantities of seeds and berries, e.g. one individual in Jun had stomach filled with juniper scales. Nestlings probably fed entirely with insects and spiders. Forages among herbs and shrubs, where very active and agile; sometimes forages on ground, investigating root tangles and lichen-covered rocks. Sometimes catches insects by aerial flycatching. In family parties after breeding season, these sometimes amalgamating to form flocks of up to 25 or more individuals; in winter months may join mixed-species foraging flocks.

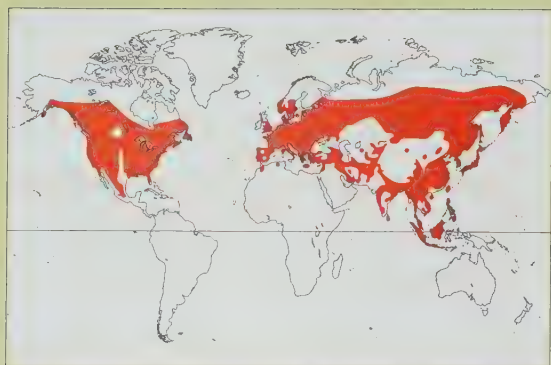

Breeding. Data mostly from Tien Shan. Laying about mid-May to mid-Jun, with replacement clutches possible until late Jul (early nests, complete in Apr, may remain empty for nearly a month); single-brooded. May form permanent pair-bonds or pair in autumn (usually seen in pairs in winter and early spring). Records of several nests in close proximity (sometimes two or three side by side), leading to suggestions of possible colonial breeding, but extra nests may be used as overnight roosts. Nest built by both sexes, work divided equally (although male may take main part in provisioning material, female in building), taking 6–8 days for framework and almost as long for lining; an oval ball c. 130–155 mm × 90–120 mm, walls up to 30 mm thick, floor up to 35–40 mm deep, circular entrance 28–35 mm in diameter on one side towards top, outer layer of coarse material such as large pieces of moss, thin stalks, spider cocoons, lichen and plant bast, inner layer of same material as well as plant hair, wool, dead leaves, feathers and the like, and lining mainly of feathers, in Tien Shan downy feathers from Himalayan Snowcock (*Tetraogallus himalayensis*) and Chukar (*Alectoris chukar*) favoured, in other parts of range (including China) those of Blue Eared-pheasant (*Crossoptilon auritum*), shape of feathers makes them stick up in nest and they thus form "elastic funnel" at entrance (when adult enters, entrance closes behind it); some nests have very few feathers and are lined instead with sheep's wool, or with plant down and marmot (*Marmota*) hair mixed with small amount of wool and feathers; nest usually very well concealed in scrub (in Gansu typically *Caragana jubata*), in Tien Shan 55–56% of nests were 0.5–1.9 m up in *Juniperus turkestanica*, usually in upper part of bush, supported by small branches at sides and base, with walls woven around larger branches, 33–36% were 2.5–15 m up in *Picea schrenkiana*, placed close to trunk on horizontal branch or 1.5–2 m from trunk and woven together with thin hanging twigs/branches (thus suspended like nest of *Regulus*); spruce may be preferred if available, and honeysuckle (*Lonicera*) occasionally used but only for replacements. Clutch 4–8 eggs, white, spotted and flecked light brown and reddish-brown, c. 15.5 × 11.7 mm (nominate race); incubation by both sexes, period 14–17 days (usually 14–15 days); both sexes brood chicks for first c. 7–8 days, and roost in nest with them; young leave nest at 18–20 days (sometimes to 23 days), but remain close to nest and roost there for 7–12 days after fledging.

Movements. In some areas mainly resident, e.g. in China reported as remaining on territory in Gansu even in bitter cold of mid-winter. Some winter dispersal reported, limited in N Pakistan (e.g. to Besham, in Indus valley), but more widely Sept/Oct to Mar/Apr in C Asia and W China. In Tien Shan of S Kazakhstan descends to foothills from early Sept/Oct, birds from Zailiyskiy Alatau occurring sporadically in Almaty, and in bad winters in Ili Depression, while those from Kungey and Terskey Alatau probably move mostly to Issyk-Kul Depression, where regular near Karakol (i.e. Przheval'sk, in Kyrgyzstan) in Oct; in W Tien Shan birds from Turkestan and Zerav'shanskiy ranges winter in Zeravshan valley, but in hard winters (with much snow) they move on to plains, reaching Samarkand in late Nov or early Dec and extreme W outposts of range, in E Uzbekistan (Payshanba and Kattakurgan), in Jan or Feb. Those reaching plains may have moved up to 100 km from breeding grounds (e.g. to Iliysk, in Ili valley, and L Sorbulak, in Almaty province). Return movements late Jan to mid-Mar. In W China recorded in winter at Golmud, in WC Qinghai.

Status and Conservation. Not globally threatened. Locally common, but absent from some apparently suitable areas (e.g. Talasskiy Alatau). Possible occurrence (presumably of race *obscurus*) in NE India, where reported sightings in NW Arunachal Pradesh, merits further study. Marked fluctuations in numbers noted in C Asia, e.g. in Almaty area of Kazakhstan very common in 1960s but almost none in 1970s, perhaps owing to high mortality in hard winter of 1968/69; densities of c. 1 pair/1–2 ha of habitat have been reported in same region. There is good evidence for a decline in Kazakhstan, where now listed as rare. Throughout range, species is vulnerable to degradation or destruction of breeding habitat by overgrazing.

Class AVES
Order PASSERIFORMES
Suborder OSCINES
Family SITTIDAE (NUTHATCHES)

- Small to medium-sized arboreal passerines with short tail, short rounded wings, and medium-long dagger-like bill; plumage grey or bluish above, with blackish eyestripe, and whitish with variable buff, chestnut or lilac below.
- 10.5–19.5 cm.

- Palearctic and Oriental Regions, with four species in Nearctic Region.
- Forest, woodland, parks and gardens; two species in bare rocky areas, cliffs, ravines and gorges.
- 1 genus, 27 species, 92 taxa.
- 4 species threatened; none extinct since 1600.

Systematics

The family Sittidae comprises a single genus, *Sitta*, which was established by Linnaeus in 1758. The members of this genus are clearly closely related and have not diverged greatly in morphology (see Morphological Aspects). Nevertheless, H. E. Wolters, in the 1979 issue of his checklist of the world's birds, divided the species among four genera, namely *Callisitta*, *Poecilositta*, *Oenositta* and *Sitta*. He placed the Beautiful Nuthatch (*Sitta formosa*) in the first of those and the Blue Nuthatch (*Sitta azurea*) in the second, while *Oenositta* contained the group formed by the Velvet-fronted Nuthatch (*Sitta frontalis*) and its close relatives the Yellow-billed (*Sitta solangiae*) and Sulphur-billed Nuthatches (*Sitta oenochlamys*); all other species he retained in the genus *Sitta*. Wolters's arrangement, however, has not been followed by other authors. As presently conceived, *Sitta* is a homogenous and well-defined genus, although the Blue Nuthatch is subtly aberrant and confirmatory evidence for its placement in *Sitta* is desirable.

The six small nuthatches of the "*Sitta canadensis* group", which usually excavate their own nest-holes, are sometimes considered to be the most primitive in the genus, but the relationships among the 27 species currently recognized have not yet been studied comprehensively by means of genetic techniques, and any such conclusions are purely speculative. The one study of nuthatches based on molecular genetics that has hitherto been published, that by E. Pasquet in 1998, included material from only ten species. Nevertheless, a tentative arrangement can be put forward, and the following is adapted from E. Matthysen's 1998 suggested relationships within the Sittidae. Wolters's genera *Callisitta*, *Poecilositta* and *Oenositta* can be retained with the same constitution but treated as subgenera, and the genus *Sitta* may then be divided into four additional subgenera. These four are subgenus *Mesositta*, with the White-tailed (*Sitta himalayensis*), White-browed (*Sitta victoriae*), Pygmy (*Sitta pygmaea*) and Brown-headed Nuthatches (*Sitta pusilla*); subgenus *Micrositta*, containing the six small hole-excavators, namely the Red-breasted (*Sitta canadensis*), Corsican (*Sitta whiteheadi*), Chinese (*Sitta villosa*), Yunnan (*Sitta yunnanensis*), Krüper's (*Sitta krueperi*) and Algerian Nuthatches (*Sitta ledanti*); subgenus *Leptositta*, with the White-cheeked Nuthatch (*Sitta leucopsis*), Przewalski's Nuthatch (*Sitta przewalskii*) and the White-breasted Nuthatch (*Sitta carolinensis*); and, finally, subgenus *Sitta*, in which the remaining nine species are placed.

While some species are distinctively different, examples being the Beautiful Nuthatch and the Blue Nuthatch, others are much less so, to the extent that the various far-flung members of the "*S. canadensis* group", particularly the Red-breasted, Corsican and Chinese Nuthatches, were often treated as conspecific, despite their massively disjunct distributions. More recently, it has become apparent that the tropical "*S. frontalis* group" comprises three species, and that the "*S. europaea*–*S. castanea* group", treated as a single species as recently as 1953, is better separated into six species. These six are the Eurasian Nuthatch (*Sitta europaea*) and Chestnut-vented Nuthatch (*Sitta nagaensis*) on the one hand, and, on the other, the Indian Nuthatch (*Sitta castanea*), the Chestnut-bellied Nuthatch (*Sitta cinnamoventris*)

The family Sittidae comprises 27 species in a single genus, *Sitta*. The nuthatches are fairly homogeneous and distinctive in their morphology. All are small to medium-sized and stocky, with a long, straight, deep-based, pointed bill, designed to help the bird open seeds. The typical nuthatch plumage pattern comprises blue-grey upperparts and whitish underparts becoming buff or cinnamon towards the vent. **Przewalski's Nuthatch** differs slightly from the norm, being one of three species that have a white face and dark crown.

[*Sitta przewalskii*, Wanglang Nature Reserve, Sichuan, China.

Nuthatches in the tropics tend to be more colourful than those inhabiting temperate zones. Three species sometimes separated in the subgenus *Oenositta* differ from other family members in that they possess a yellow iris and eyering and, in adults, a brightly coloured bill, the latter being red in the case of the **Velvet-fronted Nuthatch**. The tone of the upperparts in this group, a bright violet-blue, is also quite different from the steely blue-grey of most nuthatches. This group is also exceptional in showing a velvety-black forecrown.

and the Neglected Nuthatch (*Sitta neglecta*), with the Kashmir Nuthatch (*Sitta cashmirensis*), a taxon that had been shuffled between these two basic groups, possibly not closely related to either. The resolution of these “cryptic” species has probably not yet finished, and the Eurasian Nuthatch, even as now restricted, may well prove to be polyphyletic or paraphyletic, with the north-east Siberian subspecies *arctica*, at least, poised to be accorded the rank of a full species.

A second, independent factor has also inflated the number of nuthatches, this being the discovery of new species. The Corsican Nuthatch was described from the French island of Corsica in 1884, and at the time it must have seemed incredible that such a distinctive species of bird could have lurked undetected for so long in France. Even more astounding was the discovery of the Algerian Nuthatch in Algeria in 1975. The upshot is that 21 species of nuthatch were listed in J. L. Peters’s *Check-list of Birds of the World* in 1967, whereas the current total is 27. Indeed, this process may not have stopped, with reports in 2006 of a black-capped nuthatch in the Altai of southern Siberia; this could refer to an undescribed species or perhaps even to an astonishing range extension by the Chinese Nuthatch, but further study is required.

Two questions have puzzled taxonomists over the years. Which other “nuthatch-like” species should be placed with *Sitta* in the family Sittidae, and what are the relationships of Sittidae to other passerine genera? Among birds, as with other animals, form is often dictated by function. Several avian groups have evolved to fill a niche similar to that occupied by the nuthatches, foraging on the surface of the trunk and branches of trees or on rocks, and have thus become rather similar to the Sittidae in outward appearance. In many of the older systems of classification, a number of groups of taxa, owing to their tree-climbing habits and/or a similarity on the museum bench to the nuthatches, have been associated with the Sittidae, but does this reflect a close relationship or simply a process of convergent evolution? These groups have included the rock-climbing Wallcreeper (*Tichodroma muraria*) of the Palearctic, the treecreepers (*Certhia*) of the Holarctic, the Spotted Creeper (*Salpornis spilonotus*) of India and the Afrotropics, the Philippine rhabdornis (*Rhabdornis*), the Australasian treecreepers of the genera *Cormobates* and *Climacteris*, the Australo-Papuan sittellas (*Daphoenositta*), and the Nuthatch Vanga (*Hypositta corallirostris*) of Madagascar, the last once known by the name of “Coral-billed Nuthatch”. All of these taxa were placed either within the Sittidae or next to it in the taxonomic order, so much so that E. Mayr and D. Amadon, in 1951, described the family Sittidae as “something of a scrap-

basket”. Morphological investigations and, latterly, molecular-genetic studies have slowly untangled this complex, and the various taxa have been separated more or less definitively from Sittidae, as follows. The Wallcreeper is now accorded its own monotypic family (Tichodromidae), although some authors prefer to treat it as a subfamily, Tichodrominae, of the Sittidae. The Holarctic treecreepers form the family Certhiidae, with the Spotted Creeper as a subfamily, Salpornithinae, while the three rhabdornis species form the family Rhabdornithidae. The Australasian treecreepers are treated in the family Climacteridae, and the sittellas in Neosittidae. Finally, the Nuthatch Vanga is placed in the vanga family Vangidae.

Having established the apparent taxonomic rank of the various nuthatch-like groups, one is prompted to consider whether any of them are, in fact, closely related to nuthatches. Further, in a broader context, Sittidae has traditionally been placed close to the tits and chickadees (Paridae) and the long-tailed tits (Aegithalidae), despite differing from both of these families in many aspects of structure, plumage and behaviour. Are these implied relationships tenable? Genetic studies are now beginning to throw light on these questions in a more or less definitive manner. In 2006, K. A. Jönsson and J. Fjeldså, in an attempt to construct a tentative “supertree” of relationships among all passerine birds, reviewed 99 studies which had been based on molecular genetics. From this, they devised a new arrangement in which the oscine passerines are divided into two “parvorders”, named the Corvida and the Passerida, the former being further divided into “Basal” and “Crown” sections; the Passerida is then subdivided into three superfamilies, namely the Muscicapoidae, the Passeroidea and the Sylvioidea. The available evidence appears to support this arrangement and all of the major branches within it.

Within this scheme, the Climacteridae belong to the “Basal Corvida” and the sittellas and the Nuthatch Vanga to the “Crown Corvida”. They are, therefore, members of ancient radiations, not particularly closely related to each other and certainly not at all related to Sittidae, and they will not be considered further here. The families Sittidae, Tichodromidae, Certhiidae and Rhabdornithidae, together with the Paridae and the Aegithalidae, are members of the parvorder Passerida. Within this extensive grouping, however, the nuthatches and the certhiids belong in the Muscicapoidae, a huge superfamily other members of which include the Old World flycatchers (Muscicapidae), the thrushes (Turdidae) and the starlings (Sturnidae), but the Paridae and the Aegithalidae are members of the superfamily Sylvioidea and thus only distantly related.

Finally, within the Muscipoidea, the nuthatches are placed in the same clade as the Certhiidae, the gnatcatchers (Polioptilidae) and the wrens (Troglodytidae), while the Rhabornithidae lie in a different clade within the same superfamily. Suitable DNA data for the Wallcreeper were not available for further analysis, but data on DNA-DNA hybridization indicate that the genus *Tichodroma* is closer to *Sitta* than it is to *Certhia*, and the Wallcreeper is, indeed, as mentioned in the preceding paragraphs, still treated by some taxonomists as representing a subfamily of the Sittidae.

In conclusion, the Wallcreeper is probably the nuthatches' closest relative, with the Certhiidae also closely affiliated, whereas the Rhabornithidae are more distant, and the Paridae and the Aegithalidae much more distant still. The Australasian families Climacteridae and Neosittidae and the Madagascan Nuthatch *Vanga*, the last now in the family Vangidae, would appear to be separated from the nuthatches by many millions of years of evolution.

The genus *Sitta* seems not to be ancient. As well as dating techniques involving DNA, based upon the assumption of a relatively steady rate of change, there is the fossil record to be considered. Not surprisingly, however, fossils of nuthatches are rare. They have been found in Italy, where the fossil *Sitta senogalliensis* was discovered and was dated to the lower Miocene, about 20 million years before the present; and at La Grive St Alban, in France, where nuthatch fossil material dating from the middle to late Miocene was unearthed. Of the modern species, remains of both the Pygmy Nuthatch and the Red-breasted Nuthatch have been reported from late Pleistocene deposits at Carpinteria, in California.

Morphological Aspects

The members of the genus *Sitta* are rather homogenous and are well characterized morphologically, all having a dumpy, compact body, a short tail, rounded wings, a strong skull and bill,

short legs, and large feet with strong claws. The specialized niche that the genus occupies, that of gleaning small invertebrates, seeds and nuts from the trunks, branches and fruiting bodies of trees (see Food and Feeding), appears to have offered limited options for divergence, even when these foraging strategies are transferred to rock surfaces, as is the case especially with the Western Rock Nuthatch (*Sitta neumayer*) and the Eastern Rock Nuthatch (*Sitta tephronota*).

With regard to size, females tend to be slightly smaller on average than males, and, in general terms, species inhabiting coniferous forest are smaller than those in deciduous forest. Thus, in the "*S. canadensis* group", or the subgenus *Mesositta* (see Systematics), the sole representative in broadleaf forest, the Algerian Nuthatch, is the largest member, and in the "*S. carolinensis* group", or the subgenus *Leptositta* (see Systematics), the deciduous-forest White-breasted Nuthatch is significantly bigger than the two other species, both of which are found in coniferous forest. On the other hand, while the smallest nuthatches of all, the Pygmy and Brown-headed Nuthatches, are closely associated with pine (*Pinus*), so also is the largest, the Giant Nuthatch (*Sitta magna*). The last-mentioned species is among the heaviest of the family, at 36–47 g, but the large subspecies *dresseri* of the Eastern Rock Nuthatch is the heaviest of all, weighing up to 55 g. The smallest sittids weigh no more than 7–8 g, but most members of the family fall within the approximate range 12–20 g.

All nuthatches have a bill that is rather long, being roughly as long as the head, and robust, straight and pointed. It is well suited for the opening of large seeds such as acorns and hazelnuts (*Corylus*), although smaller seeds, such as those of pine and beech (*Fagus*), are taken more frequently. The nostrils, positioned near the base of the bill, are rounded and partly covered with feathers, and the rictal bristles are short and soft. The legs are short, with the tarsus distinctly scutellate, and with strong feet and large, laterally compressed claws; the feet of the two rock nuthatches are proportionally slightly longer and the toes, especially the hind toe, relatively short. Nuthatches are agile climbers, placing one foot above the other and progressing with a series

The Eastern Rock Nuthatch is the heaviest member of the family, with one race weighing seven times that of the smallest sittid. In some characteristics, this species is typical of its family; in others, it is definitely atypical. Like its congeners, it has a short tail, long but rounded wings, short legs and strong feet. In common with the closely related Western Rock Nuthatch (*Sitta neumayer*), however, the Eastern Rock Nuthatch has relatively longer feet but shorter toes than a typical sittid. These morphological differences are adaptations to a life spent on rock surfaces, a habitat preference that distinguishes this pair within the otherwise arboreal family.

& Christel Freidel/Bios]

The morphological homogeneity of Sittidae is no doubt related to its confused taxonomic history.

While the **Eurasian Nuthatch** is now generally considered to form a superspecies with five other forms, all six were normally treated as conspecific until 1953. Even within the revised limits of the Eurasian Nuthatch, there is much geographical complexity. Twenty-two subspecies, differing externally in plumage coloration and size, are currently recognized, and are normally divided into four groups, but morphological research and (admittedly incomplete) assessments of mitochondrial DNA point towards a more subtle treatment, although even this may not be evolutionarily accurate.

The ranges of the "nominate group" and the "asiatica group" overlap without hybridization, suggesting that they may represent distinct species.

On the basis of genetic material, race arctica of north-east Asia may also merit separate species status. Meanwhile, several subspecies pairs intergrade. Such is the case with the two European forms seen here: nominate europaea (above), broadly of the north and east of the continent; and caesia (below), of the south and west.

[Above: *Sitta europaea europaea*, Hanko, Finland. Photo: Markus Varesvuo.]

Below: *Sitta europaea caesia*, Herrenhäuser Gärten, Hannover, Germany. Photo: Stefan Pfützke]

Most members of Sittidae are dependent on trees and thus principally inhabit forests or woodland.

The **Eurasian Nuthatch** prefers mature, old-growth forest with large trees and an extensive canopy, habitat that provides its needs for nesting cavities and arboreal foraging grounds. Within these broad requirements, the large range of the Eurasian Nuthatch means that it inhabits a variety of woodland types. In much of Europe and the Far East, it prefers deciduous and mixed forest, particularly oak (*Quercus*) or beech (*Fagus*), but it inhabits coniferous forests elsewhere.

[*Sitta europaea caesia*, Fageda de la Grevolosa, Sant Pere de Torelló, Spain.

Photo: Eudald Solà]

of jerky hops. They are able to move along the underside of branches, hanging upside-down, and they descend trunks head first with ease, but they do not use the tail as a prop when climbing. Thus, despite their close relationship with the treecreepers, and their often similar arboreal micro-habitats, the mode of progression is very different. A further difference from the treecreepers is that nuthatches are at home also on the ground, where they typically progress with a series of hops. Unlike the

parid tits and the babblers (Timaliidae), nuthatches do not use their feet to hold down large or awkward food items in order to break them up, but, rather, they wedge nuts and similar items into crevices and hammer them with the bill, using the power of the whole body.

Nuthatches have rather short, bluntly pointed wings consisting of nine secondaries and ten primaries, the outermost primary being significantly reduced, with a length no more than about

Across its large distribution in North and Central America, the **White-breasted Nuthatch** inhabits a variety of forest types. The key ingredients are mature or dead trees with potential nesting cavities. In the east of its range, this species favours open deciduous forest, often with oak (*Quercus*) and beech (*Fagus*). Here, as in the boreal north, it shuns coniferous forests, yet it breeds in pine (*Pinus*) and oak-pine to the south and west. Interestingly, the two fellow members of the subgenus *Leptositta*, the **White-cheeked Nuthatch** (*Sitta leucopsis*) and **Przewalski's Nuthatch** (*S. przewalskii*) are confirmed coniferous forest specialists.

[*Sitta carolinensis*, Washington, USA.

Photo: Dave Maslowski/Maslowski Productions]

While their congeners are inextricably linked to trees, two species of nuthatch have evolved to deploy the classic sittid foraging strategy on a different substrate: rock surfaces. They comprise a species pair, the **Western Rock Nuthatch** and the **Eastern Rock Nuthatch** (*Sitta tephronota*). Both species are tied to bare rock in its many forms—from rocky slopes and cliffs to ravines and gorges. Limestone is a particular favourite, its numerous cracks and crevices offering abundant nesting possibilities. Both species also frequent artificial alternatives to rocks, such as buildings.

40% of that of the longest primary. Their flight is fairly strong, and over short distances direct, but on longer flights the wings are periodically closed, producing an undulating flight pattern. The tail is distinctively short, broad, square or slightly rounded, and straight, with twelve feathers.

For the most part, the members of this family are remarkably conservative in the coloration of the plumage and bare parts. A typical nuthatch has the bill greyish to blackish with a darker tip; the upperparts are blue-grey, with a contrastingly blackish eyestripe, the tail has subterminal white spots, and the underparts are whitish, grading to buff, chestnut or lilac on the flanks and vent, with the undertail-coverts sometimes spotted paler. Some species have a pale nape spot, but this, when present, is often fully concealed; its purpose is obscure. Variations on this theme are few. A black forehead or cap is exhibited by the “*S. canadensis* group” and the “*S. frontalis* group”, a white face and a dark cap characterize the White-breasted, White-cheeked and Przewalski’s Nuthatches, white in the central tail feathers is a feature of the White-tailed, White-browed and Pygmy Nuthatches and, marginally, the Brown-headed Nuthatch, and well-marked upperparts distinguish the Beautiful Nuthatch. In addition, the members of the “*S. frontalis* group” possess a yellow eyering and a red or yellow bill. The Blue Nuthatch is the most anomalous in having the upperparts and the belly and vent almost blackish; moreover, the structure of its plumage differs in that the greater upperwing-coverts are slightly elongated and drooping, and the feathers of the nape are thick and velvety.

The sexes of *Sitta* species differ only from each other slightly, typically in the intensity of buff or chestnut pigment on the underparts and, in the case of dark-capped species, in the extent of blackish on the crown. Juveniles are very similar to adults, and are usually distinguished, with difficulty, by the fact that they have slightly duller coloration, “looser” plumage, and moult contrasts in the greater coverts and fresh remiges and rectrices at a time when the adults have worn and abraded plumage. With the Eurasian Nuthatch, and probably other species, too, skull pneumatization is of limited use, as adult nuthatches never attain the state of a fully pneumatized skull, and only scores of 1–2 can be used to indicate first-year individuals.

Adults undergo a complete post-breeding moult, which, in the Eurasian Nuthatch, commences about a week before the young

fledge and lasts for around 88 days. Juveniles acquire first-winter plumage by means of a partial moult involving some wing-coverts and, for some species, also some of the tertials and central tail feathers. There is some evidence that early-fledged juveniles of the Eastern Rock Nuthatch also replace the outer six primaries. The adults of some members of the family have, in addition, a partial pre-breeding moult in which they renew variable amounts of the body plumage, usually on the underparts, and especially

The strong legs and feet of sittids equip them well for a life spent largely on tree trunks. In addition to the **Spotted Creeper** (*Salpornis spilonotus*) of the Afrotropics and India, nuthatches are the only other birds able to descend trees head first. In contrast to treecreepers (*Certhiidae*) and woodpeckers (*Picidae*), amongst others, nuthatches do not use the tail as a support when ascending. Sturdy toes and laterally compressed claws also enable sittids such as this **Eurasian Nuthatch** to sleep while clinging firmly to the vertical bark surface. Roosting in the open is commoner in summer, when heat loss is not a significant problem.

[*Sitta europaea*,
Russia.
Photo: Roland Seitre]

In general, nuthatches are easy to identify, but the "S. europaea group" and the two rock nuthatches can present significant challenges, and the lack of distinctive stereotyped songs means that voice is of only limited use in their separation. In most cases, the species in question is the only member of its family throughout most of its range, the major exception being in the Himalayas and south-west China, where several species may be present, albeit often separated altitudinally. Elsewhere, the ranges of the two rock nuthatches overlap in the Middle East. The Western Rock Nuthatch and the Eastern Rock Nuthatch are clearly closely related, and have come to be regarded as the classic example of what is termed "character displacement". In the regions where just one of these two species is present, they are very similar to each other in appearance. Where their ranges overlap, however, they differ markedly in size, in bill length and in the prominence of the dark eyestripe, and it is suggested that competition between them has intensified the differences in the area of range overlap, thus allowing the two species to co-exist.

A detailed analysis by P. R. Grant, in 1975, showed that the situation was not so clear-cut as had been proposed, and that variation in some characters, such as bill size, rather than being "displaced", could be merely a continuation of trends exhibited outside the zones of overlap. Grant concluded, however, that, in areas where the two rock nuthatches overlapped geographically, the body size and, especially, the size of the eyestripe had undergone mutually divergent character displacement. The exaggerated differences in body size may result in different food resources being utilized, and, although bill size has not been "displaced", the two species exploit seeds of different sizes in areas where they overlap, thus reducing competition between them. Importantly, the differences in the eyestripe help in species recognition. Thus, in many displays, the eyestripe, made more conspicuous by the raising of the feathers, conveys information on the bird's species identity; the act of bobbing is thought to give information on the bird's size; and the type of display gives information on the bird's sex, the male adopting a vertical posture and the female a crouching position. In areas where the two species differ markedly in the prominence of the eyestripe, therefore, they are able to co-exist, to have overlapping home ranges and to feed within a few metres of each other without conflict. In fact, song, too, may be important in species recognition, as the songs of the two species, although similar, are given at differing frequencies, that of the Western Rock Nuthatch being higher-pitched than that of its relative, although the distinctions are far from clear-cut, at any rate to the human ear.

Like many passerines, nuthatches are wary when they bathe, remaining alert for predators and other potential threats. This **Pygmy Nuthatch** is standing in the still, shallow water of a birdbath. *Sittids* are thought to foliage-bathe after rain and rain-bathe during drizzle. Birds indulge in two forms of bathing. In one, the feathers are moistened but not soaked; this approach appears to assist preening by making the feathers more pliable or by evenly distributing uropygial oil. In the second form of bathing, the feathers are completely soaked; the aim here is to clean the feathers and skin thoroughly.

[*Sitta pygmaea melanotis*, Kaleden, British Columbia, Canada.

the throat and breast feathers, but including also the cheeks and sometimes the nape and mantle. It seems, however, that this moult is very limited in extent and that many or most individuals, even of those species for which the phenomenon has been recorded, do not moult prior to breeding, although it is hard to draw definite conclusions as signs of this moult are difficult to detect in museum specimens. Given that only a proportion of nuthatches have a pre-breeding moult, it is interesting to speculate on the purpose of this moult. If its function is to replace worn and abraded plumage, why would only a proportion of individuals moult, and what would trigger the process? One suggestion is that is possibly the last vestige of a moult into a distinct breeding plumage, one which no longer exists.

Sittids are highly vocal birds, although the vocalizations tend to attract attention more for their volume than eloquence. Most are variations on a simple theme, being repetitions of notes at various speeds. In some species, the song appears simply to be a louder and longer version of the call. This is perhaps less the case with the **Western Rock Nuthatch**, however. The male's song, usually given from the top of a rock or other conspicuous perch, is a complex, loud whistling trill; males have a repertoire of four song types. Females may also sing, and, in some areas, pairs duet.

[*Sitta neumayer syriaca*, Alahan Monastery, Turkey. Photo: Hanne & Jens Eriksen]

Like most other species of *Sitta*, the **Brown-headed Nuthatch** is a vocal bird.

Members of foraging groups keep in contact with a soft call which is uttered up to 90 times per minute, thus sounding like twittering. Should an individual become detached from the group or become otherwise excited, it may give a loud, bisyllabic squeaky call that has been likened to the noise made by a toy rubber duck being squeezed and then released. A series of double notes in a similar tone is what passes for the male Brown-headed Nuthatch's song. The Pygmy Nuthatch (*Sitta pygmaea*), formerly treated as conspecific, has similar vocalizations.

[*Sitta pusilla pusilla*, near Marumscoc, Maryland, USA.

Photo: George M. Jett]

These mechanisms of character displacement nevertheless appear not to be fully developed in every region where the two species overlap in range. In northern Iran, in particular, the differences in the eyestripe dimensions are reduced and the two species appear unable to co-exist, the Western Rock Nuthatch being found at higher elevations than those occupied by the Eastern Rock Nuthatch, despite the fact that there are marked differences between them in bill size. Here, the possibility of "reproductive confusion" seems to keep the two species apart, despite a lack of ecological competition.

Habitat

All except two members of the family Sittidae are closely tied to forest or woodland and forage almost exclusively in trees, the exceptions being the aptly named rock nuthatches. Although some species will forage in the shrub layer or on the forest floor, such behaviour is relatively infrequent. Both coniferous and deciduous broadleaf forests are utilized by nuthatches, but many species are rather specialized and closely tied to either deciduous stands or coniferous forest. The six members of the "*S. canadensis* group" (see Systematics) are closely tied to conifers, as also are the Pygmy and Brown-headed Nuthatches, whereas the six species in the "*S. europaea* complex" are associated with broadleaf woodland, although many individuals of the latter group will also use conifer forest. The White-breasted, White-cheeked and Przewalski's Nuthatches are apparently closely related to one another (see Systematics), but while the White-cheeked and Przewalski's are very closely tied to coniferous forest, the White-breasted is a denizen of deciduous forest in the eastern USA, although it will exploit conifers, especially pines, in the south and west of its range.

Parks and gardens with old trees attract nuthatches, which in some parts of their ranges also visit garden feeders. In Europe, for example, the Eurasian Nuthatch is a frequent visitor to birdtables and suspended birdfeeders, and it will even breed in large gardens if these contain suitable nesting sites.

All forest-dwelling nuthatches are cavity-nesters, and the availability of suitable nest-sites may be an important factor in habitat quality. Older trees, and especially standing dead wood, can provide many suitable sites, both for those species which excavate their own cavities and for those which take over existing holes. Modern forestry practices frequently involve the removal of such trees, and this may limit the suitability of intensively managed forests (see Status and Conservation).

The two rock nuthatches are aberrant in their choice of habitat. They favour areas of bare rock, such as rocky slopes, cliffs, ravines and gorges, frequently on limestone. The structure of limestone, with many fissures, cracks and cavities, may provide more potential nest-sites than do harder igneous rocks. These two species take readily to man-made structures, especially old buildings and ancient ruins. Both are found in arid regions. The Western Rock Nuthatch is very much a bird of open country, although it will enter open rocky woodland, but the Eastern Rock Nuthatch is more often found in wooded country, albeit usually with areas of exposed bare rock, and it will nest in tree cavities.

General Habits

The nuthatches are a family of small but conspicuous birds, most of which remain throughout the year in the same general area. They would seem to be ideal subjects for study and, indeed, the Eurasian Nuthatch in Europe and the four Nearctic species have received a good deal of attention, as a result of which some aspects of their behaviour are well known. The same cannot be said for the Asian species, for which data are severely limited. In discussion of the habits of the Sittidae, therefore, most of the information derives from a limited set of five species, and only by inference can it be extended to the other 22. This lack of information is probably especially true in respect of those species resident in tropical and subtropical regions.

Nuthatches are almost unique in the ability to climb head first down a tree trunk, the Spotted Creeper being the only other avian species to have been recorded as climbing thus. They walk up and down, always holding one foot firmly on the bark while the other is moved. When climbing upwards they typically move in a zigzag pattern, maintaining the centre of gravity directly above the lower foot. Some species, especially the smaller nuthatches, can hang upside-down below a horizontal branch, but the larger members of the family seem to find this difficult; the latter will move from side to side on the upperside of a branch, presumably in order to maximize their reach on to the sides and lower surface without actually clinging below it. While moving along such horizontal surfaces, as well as on the ground, nut-

Nuthatches are primarily arboreal foragers. They move about trees actively, hanging upside-down, descending trunks head first and scouring the underside of branches with acrobatic ease. This is true of the **Velvet-fronted Nuthatch**, which mainly searches for food on tree trunks, particularly in the middle and upper storeys. Less frequently, it forages on branches and, occasionally, in the undergrowth or on fallen logs. The bulk of the nuthatch diet comprises insects and other small invertebrates such as spiders (*Araneae*).

[*Sitta frontalis saturator*, Pantu Forest, Johor, Malaysia.

Photo: Morten Strange]

Nuthatches make wide use of the food supplies offered by their environment. In addition to invertebrates, they consume seeds, which, in the **Red-breasted Nuthatch**, are mainly taken in the non-breeding season. This species is strongly associated with coniferous and mixed forests, so it is not surprising that conifer seeds are a staple, but it also readily eats seeds from other plants such as sedges (Cyperaceae). In autumn, particularly, Red-breasted Nuthatches descend from the canopy to the ground in search of fallen seeds. Individuals accustomed to the presence of humans also enter gardens to take seeds from feeders.

[*Sitta canadensis*,
Lac St-Charles, Quebec,
Canada.
Photo: Daniel Houx]

nuthatches hop, rather than walk. The rock nuthatches, being essentially terrestrial, rarely climb downwards head first, and they hop, rather than climb, upwards.

Behaviour associated with maintenance and comfort is as would be expected for a passerine group. Head-scratching is usually achieved by the indirect method, the leg being brought up over the top of the outstretched wing, but the Corsican Nuthatch has been recorded as scratching directly, and some, especially the smaller species, head-scratch while hanging upside-down. Allopreening has been recorded repeatedly for the Brown-headed Nuthatch and may help to maintain the pair-bond, and there is an observation of reciprocal preening between an adult male and the

helper male of a neighbouring pair. Allopreening has been recorded also among flocking Pygmy Nuthatches, one individual gently nudging the head of another with its bill. Nuthatches will bathe in shallow standing water or in snow, but only rarely, and they are very wary when doing so. They probably favour foliage-bathing after rain and rain-bathing in drizzle; indeed, the latter habit is thought to be normal practice for the White-breasted Nuthatch. Two sunning postures have been recorded for the Eurasian Nuthatch, but sun-bathing must be uncommon. No members of the Sittidae have been observed to indulge in anting behaviour.

All nuthatches are assumed to be territorial during the breeding season, and adults of most or all species probably hold a ter-

In large parts of its range, the **Eurasian Nuthatch** inhabits oak (*Quercus*) forests, where acorns form part of its diet. Likewise, hazel (*Corylus*) nuts and beech (*Fagus*) mast are common foodstuffs in some areas. To gain access to the edible material in such large seeds and nuts, the nuthatch has to use its robust bill for manipulating, opening and extracting. During the winter cold, this species may need to spend nine-tenths of the day foraging in order to satisfy its energy requirements.

[*Sitta europaea caesia*,
Sant Nazari, Barcelona,
Spain.
Photo: Eudald Solà]

When foraging, nuthatches locate their food by sight or by touch. The arboreal species use their long bill to probe crevices in tree trunks or branches, and, as in the case of this **Giant Nuthatch**, to remove small pieces of bark that might conceal small invertebrates. This species, the largest sittid, principally forages in the canopy of mature pines (Pinus), only descending to the trunk on occasion. As befits its size and bulk, the Giant Nuthatch is less active than its congeners, moving rather sedately around and between trees. It is also less gregarious than other nuthatches, usually feeding alone or in pairs.

[*Sitta magna ligea*,
Zixishan Mountain,
Chuxiong, Yunnan, China.
Photo: Li liwei]

ritory throughout the year, the exceptions being the irruptive or migratory populations of the Eurasian and Red-breasted Nuthatches. Individuals of the latter species which do not move south in winter maintain a year-round territory, whereas migrants, naturally, do not. The maintaining of permanent year-round territories is, however, a relatively rare phenomenon among small passerines in temperate latitudes, being commoner among larger birds and among passerines in tropical areas, and the year-round occupation of a territory by nuthatches may be linked to the habit of caching food. In fact, a well-resourced winter territory may be essential to survival, especially if large quantities of food have been cached during the summer and autumn periods. Some nut-

hatches, however, are more sociable than others. The Eurasian Nuthatch appears to be the least so, while the Pygmy Nuthatch and the Brown-headed Nuthatch, being co-operative breeders (see Breeding) and, in the case of the Pygmy Nuthatch, roosting for much of the year in flocks, are the most sociable and least territorial of the family; for different reasons, the Red-breasted and Pygmy Nuthatches form single-species flocks outside the breeding season. The various Oriental nuthatches are very poorly known, but members of the "*S. frontalis* group", namely the Velvet-fronted, Yellow-billed and Sulphur-billed Nuthatches, and the Blue Nuthatch are regularly seen in small groups as members of mixed-species flocks, while the Beautiful Nuthatch has been

For such a restless species, constantly on the move in small, vocal groups or as part of mixed-species flocks, the **Blue Nuthatch** is a rather diligent and patient forager. In contrast with other nuthatches, which actively probe or glean for food, this species spends long periods simply scanning for its insect prey. Only when it notices movement does the bird launch a rapid attack. This species' morphological idiosyncrasies, such as elongated, drooping greater upperwing-coverts and thick, plush nape feathers have led to speculation that the Blue Nuthatch might be better placed outwith Sitta.

[*Sitta azurea expectata*,
Fraser's Hill, Malaysia.
Photo: Jimmy Chew]

found in relatively large flocks, once an amazing 21 together, but the extent to which these groups are linked to any territory is completely unknown. Nuthatches are very often members of mixed-species foraging flocks, but they do not wander with the flock; rather, they join a flock as it enters their territory and leave it as it moves out.

In the case of the well-studied Eurasian Nuthatch, the members of a territorial pair tend to stay in close contact, often forag-

ing in the same tree or a neighbouring one, and calling frequently. If they lose contact with each other, the volume and intensity of the calling increase. For most of the year males are dominant over females, but this is reversed during the nest-building period. Young birds frequently switch mates and territories, but adults are much more faithful. It seems, however, that they are probably faithful to the territory, rather than to the mate, and that both male and female have a long-term interest in defending the same territory.

The territory is defended to a variable extent, depending on the time of year. Adult Eurasian Nuthatches tolerate wandering juveniles to some extent in late summer, but in September–October they defend the territory vigorously, and the pair is again especially vigilant in the early spring. Disputes with other nuthatches on the borders take the form of calling, display and short chases, in which both sexes participate. Territory-owners respond most strongly to intruders of the same sex, and in general male–male conflicts are more intense. Disputes can be prolonged, but they seldom result in changes to the territory boundaries. In mild threat display, the nuthatch raises and spreads the tail, points the bill upwards and holds the wings half-opened and drooped. In the more intense display, the body feathers are sleeked and the tail and wings opened more widely, and in great excitement the wings are beaten. Short but intense fights have been reported as being not uncommon in some studies but were found to be rare in others. In these conflicts, the combatants grapple with their feet while pecking, and often fall to the ground together; injury and even the death of one individual may result. A strange facet of territorial behaviour of the Eurasian Nuthatch is the occurrence of trios, when a single individual occupies two different territories, having a different mate in each territory. Such arrangements, however, are transitory and occur only outside the breeding season.

Most or all pairs of the White-breasted Nuthatch also maintain a territory throughout the year, although some individuals may have separate summer and winter territories, and they may temporarily leave their territory to visit a rich food source, such

The diet of the **Chestnut-vented Nuthatch** is not documented, perhaps largely because until recently the species was considered conspecific with the Eurasian Nuthatch (*Sitta europaea*). However, it is unlikely to differ greatly from other sittids, probably comprising small arthropods and seeds. This individual is using its long, pointed bill to probe between the scales of a pine cone. Somewhat unusually, among the mainly arboreal members of the Sittidae, the Chestnut-vented Nuthatch forages on the ground, even on rocks, as well as on trees.

[*Sitta nagaensis montium*, Laifeng Shan, Yunnan, China. Photo: John & Jemi Holmes]

As might be expected for a species with a fairly large range, the breeding seasonality of the **Velvet-fronted Nuthatch** varies with location. It can start as early in the year as January in south India and finish as late as August in Java. Unlike many tropical passerines, however, it does have a tightly defined breeding season at each locality and does not breed throughout the year. Like almost all congeners, the Velvet-fronted Nuthatch places its nest in an existing hole, often one abandoned by a woodpecker (Picidae) or barbet (Capitonidae), rather than excavating one afresh. The chosen hole may be too small, in which case the birds enlarge it to a suitable diameter.

[*Sitta frontalis corallipes*, Kinabalu Park, Sabah, Borneo. Photo: John & Jemi Holmes]

as a garden feeder. The territories of this species are relatively large, and encounters with neighbours are infrequent. Once independent, all juveniles leave the territory in which they were raised, and then either establish their own territory, often after pairing, or become what are known as "floaters". Floaters are probably all wandering immatures without territories, and they will replace any member of an established pair that dies or otherwise disappears.

Among Brown-headed Nuthatches, males probably maintain permanent territories around the nest-hole, singing and chasing away other males. Those pairs with helper males hold larger territories than simple pairs, but these larger territories, and those of non-breeding pairs, may overlap more extensively with those of their neighbours. Family-members of this species tend to remain together through the autumn and winter, and forage beyond the territorial boundaries. These small parties sometimes amalgamate to form single-species flocks, up to 24 individuals having been recorded together, or they join mixed-species foraging flocks.

The Pygmy Nuthatch also tends to form permanent pair-bonds. Each pair maintains an all-year territory, selected by the male and comprising the nesting and roosting sites and the foraging areas. As with the Brown-headed Nuthatch, territories of pairs with helpers are, on average, larger than those of pairs without helpers. Territories sometimes overlap, but they are actively defended only in the breeding season, defence usually being limited to the vicinity of the nest-site; possession of a territory is announced with song. The adult pair of Pygmy Nuthatches and its fledged brood tend to stay together in the autumn, sooner or later forming stable winter groups with other families. These groups roam over an area formerly occupied by several territories, and occasionally wander more widely. In some areas this species tends to form single-species groups, usually containing 5–16 and occasionally up to 100 individuals, but in montane habitats it joins mixed-species foraging flocks. Flocks break up in the spring, at which time the surplus young are usually driven off, exclusion from the roost-site being perhaps an important factor

in this process. Young males, however, may be allowed to remain as helpers, and some may remain as floaters, neither breeding nor helping.

One obvious question is that of how young nuthatches establish a territory. Upon fledging, juveniles usually spend a relatively short period of time with their parents, and then disperse, the exception to this general rule being the Pygmy Nuthatch, in which the family group goes on to form a winter flock. The immediate task for a juvenile nuthatch upon dispersal is to acquire a territory and a mate. Four major studies of the Eurasian Nuthatch, one in each of the countries of Belgium, Germany and Sweden and one in Siberia, have revealed four different patterns of behaviour, probably reflecting the interacting effects of habitat structure and quality, survival rates and variation in food supplies. In the summer season, territories may "saturate" a habitat, with well-defined territorial borders and leaving no "empty" space. In the winter months, they may be less densely packed, with less clear-cut borders. There are conflicting data on seasonal changes in territory size, but a tendency exists for territories to be smaller in summer. At the highest population densities, Eurasian Nuthatch territories can occupy only 1 ha, but at more typical densities they cover 2–3 ha of forest, and in poor-quality coniferous habitat in Siberia a territory can span as much as 30 ha. Clearly, for a bird that communicates by sight and sound, behaviour appropriate to a territory of 1 ha may be very different from that in a 30-ha territory.

Matthysen, in his study of the Eurasian Nuthatch in Belgium, found that juveniles typically set up territory rather quickly, within 2–4 weeks of fledging, and the earlier a territory is established, the more likely it is to be in good-quality habitat. This clearly favours nuthatches that breed early, and it could also help to explain why second broods are rare, as late-fledging juveniles would acquire poor territories. The acquisition of a territory, probably by an individual of either sex, appears to be followed almost immediately by the acquisition of a mate. There is little evidence that juveniles evict existing pairs, but, rather, they take over vacant territories, and there may be numerous disputes along the

Sittids are almost exclusively cavity-nesters.

The **Eurasian Nuthatch** breeds in pre-existing tree holes that may either be natural or excavated by another species, usually a woodpecker (*Picidae*).

Holes tend to be 2–20 m above ground. On occasion it is inventive in its choice of nest location, some pairs using nestboxes, holes in walls or rocks, or crevices between tree roots. More outlandish nest-sites recorded include a haystack and an old nest of a Eurasian Magpie (*Pica pica*). The female is thought to have the final say on the choice of nest-site, and she has ample time to reach a decision, as pairs stay in contact and within their territory throughout the year.

[*Sitta europaea hispaniensis*,
Sevilla, Spain.

Photo: José María
Fernández Díaz-Formentí]

Early in the breeding season, nuthatches can sometimes be seen on the ground in areas of wet, bare soil. The birds are not foraging, but collecting mud. The mud forms the basis of a plaster-like substance that they use to reduce the size of the entrance to the nest hole. In this respect, the two rock nuthatches (here the **Western Rock Nuthatch**) are somewhat anomalous. While occasional individuals follow the usual *Sitta* practice of nesting in a pre-existing cavity, which they seal with mud, for these two species the mud's primary use for the substance is as the main building material for the entire nest. The nest takes the male 10–18 days to build: the final construction is large and flask-shaped.

boundaries as they do so. Fairly quickly, it appears, all suitable territories have been occupied, and the remaining juveniles, still lacking a territory, can acquire one only by filling vacancies within the established pattern of territories. There seem to be different tactics employed in order to achieve this. In the late summer, especially, some individuals occupy a "home range" which may overlap with established territories but which they do not attempt to defend; such juveniles are quiet and inconspicuous, and subordinate to the local territorial pairs, but they are "on the spot" and ready to fill vacancies as they arise. Other birds continue to wander, and males in this itinerant subpopulation, as well as stepping into the shoes of the deceased, probably actively usurp other males from existing territories.

Surviving adult pairs almost always remain on the same territory from year to year, but juveniles do not usually breed on the first territory that they occupy. The death of one partner or, less often, the splitting-up of a pair, prompts periodic reshuffles or territory "shifts", and offers those nuthatches still without a territory the chance to acquire one. Not all territories are of the same quality, of course, and some are abandoned as the breeding season approaches, perhaps because they are not of a sufficiently high quality to support a breeding attempt and, moreover, their occupants have the opportunity to shift to a higher-quality territory that has fallen vacant.

The Belgian study is not representative of the behaviour of the Eurasian Nuthatch throughout its vast range. In studies in Germany in the 1950s, H. Löhrl found that some juveniles established new territories by squeezing into gaps, behaviour unknown in Belgium, or by aggressive takeovers, which were rare in Belgium. Juveniles wandered or associated with the adults until August, when they began to form pairs. As there were few vacant territories, they squeezed into gaps between existing territories. Juvenile pairs gradually expanded these territories, at first without experiencing conflicts with neighbours, but in September–October they initiated conflicts and expanded the territory at the expense of neighbouring ones, and territory

boundaries thus varied over time. Conflicts began again in the spring, lone males or pairs aggressively taking over territories. In several more recent studies, in Sweden, B. Enoksson and S. G. Nilsson showed that territory size was related to the food supply, and that in years of plenty large territories were subdivided. In Siberia, V. V. Pravosudov found that juveniles remained as non-territorial individuals, sometimes in pairs, within adult territories; several juveniles could have home ranges within the territory of an adult pair, but they did not associate with each other or with the adult pair. These non-territorial birds could remain for prolonged periods, sometimes for more than a year but without breeding, until the death of a territory-holder provided a vacancy. There was no evidence of aggressive takeovers, and no "squeezing-in".

All the Sittidae of temperate regions are relatively small and have therefore to cope with substantial energy losses overnight, especially during the winter months. Of the well-studied species, the Eurasian Nuthatch almost always roosts singly and only occasionally are two individuals found sleeping together. It roosts in cavities, including nestboxes, and less often behind loose bark, and it sometimes roosts in the open, especially during the summer; less usual sites include chimneys. When the nest is complete, the female regularly uses it as a roost, continuing to do so for up to 16 days after the eggs hatch. The White-breasted Nuthatch is ecologically close to the Eurasian Nuthatch and, as the latter, roosts singly in tree holes and also behind loose bark. In very cold weather, however, several White-breasted Nuthatches may roost together, and there is a record of 29 individuals packed into a single roost-site. Notably, roosting White-breasted Nuthatches remove their faeces from the hole when emerging in the morning, and this behaviour has been reported also for the Eurasian Nuthatch. The roosting behaviour of the Red-breasted Nuthatch is not well studied. It is known that both members of the pair roost together in the nest-hole during the incubation stage and that the female roosts with the nestlings until they fledge. Red-breasted Nuthatches that are resident may use cavities as

Upon choosing a nest cavity, most sittids reduce the size of the entrance, apparently so that only they can pass through it.

This they do by "plastering" up the hole. The main substrate in the "plaster" is mud, but animal faeces, rootlets and moss are common additional components.

This **Eurasian Nuthatch** is at the start of such a plastering process, with a bill full of wet mud. The female takes almost exclusive responsibility for this task, the male providing only occasional help. The plastering is thought to deter predators from raiding the nest and to reduce competition for the cavity from larger species, such as, for the Eurasian Nuthatch, Great Spotted Woodpeckers (*Dendrocopos major*) and Common Starlings (*Sturnus vulgaris*).

A secure nest-site is thus a precious commodity that is often used in successive years. In addition to plastering the nest entrance, the female Eurasian Nuthatch gathers material to construct the nest inside the cavity. With natural protection offered by the tree, nuthatches have little need for an elaborate nest. Wood chips provide the foundation, and these are covered with a layer of bark flakes, perhaps chosen for their anti-parasitic properties, and occasionally lined with a few dry leaves or strips of lichen.

[*Sitta europaea caesia*,
Bavaria, Germany.
Photo: Konrad Wothe]

The "plaster" applied by this **Eurasian Nuthatch** to the entrance of its nest dries rapidly to become very hard. Only a bird with special morphological adaptations, such as a **Great Spotted Woodpecker** (*Dendrocopos major*), stands a chance of hammering through this defence to take over the cavity. Despite the **Eurasian Nuthatch's** wide range, its breeding seasonality is fairly homogeneous, latitude and altitude accounting for the limited variation. Females usually lay eggs in April or May, very occasionally as early as February. Pairs are almost exclusively single-brooded.

roost-sites during the non-breeding season, but this has not been well documented, and little is known of the roosting habits of migratory individuals of this species.

Of course, it is the smallest nuthatches, the **Pygmy** and **Brown-headed Nuthatches**, that would be expected to suffer the most stress during cold nights, and fairly extensive investigation of the roosting behaviour of these species has revealed some astonishing behaviour. The **Pygmy Nuthatch** roosts throughout the year exclusively in tree cavities, and always socially; so far as is known, there are no records of **Pygmy Nuthatches** roosting alone. In the breeding season the pair and, if present, the helper roost in the nest-hole, and, once the young fledge, the family party may for a few days return to the nest to sleep, but then switch to a summer roosting cavity, sometimes shared with other family groups. In autumn and winter social roosting is normal, and, exceptionally, over 100 individuals have been recorded as using a single large cavity; in one case, a total exceeding 160 was counted in the same dead stub, the roosting individuals belonging to 5–10 distinct social groups. The birds either cling to the wall of the cavity, typically in wedge formations, in close body contact, the heads all pointing in the same direction, or lie stacked at the bottom of the cavity, with as many as five layers of nuthatches. Two conflicting factors affect the birds' behaviour in these roosts, one being the thermal advantage provided by close body contact and the higher ambient temperature in a sheltered cavity, and the other the need to have a sufficient through-flow of air to prevent suffocation. The importance of the latter is illustrated by the gruesome discovery in one cavity of the remains of up to 13 mummified nuthatches, which may have been suffocated. As the night progresses, the birds may change formation in order to match the changing conditions. Not surprisingly, there are clear seasonal patterns in the selection of roost-sites. Winter roosts have a smaller entrance and thicker walls than do those used during the rest of the year, and in the winter months the nuthatches select cavities in trunks in preference to those in branches, the former being large enough to hold more individual birds. On warm summer nights, cavities with a large entrance hole, often with additional cracks and openings, are chosen. This species has been recorded as roosting also in nestboxes. Communal roosting is an adaptation designed to enable this small species to survive very cold nights. The tempera-

ture and the presence of snow influence both the timing of roosting and the size of the roost flock; nuthatches go to roost earlier as the temperature drops and, the colder it is, the larger the number of individuals that sleep together. Roosting **Pygmy Nuthatches** may also enter a state of hypothermia, lowering the body temperature by at least 10°C in order to minimize energy expenditure and becoming extremely lethargic. Indeed, in periods of heavy snowfall, when conifer-needle clusters, the usual forag-

White-breasted Nuthatch pairs divide parental roles during their lifelong association. The female constructs the nest from material collected by the male, pictured here. The basic nest structure is formed from wood chips, bark strips, mud, grass and leaves. Soft material such as fur is used both as a nest lining and to fill the cavity. Females of this species and the **White-cheeked Nuthatch** (*Sitta leucopsis*) perform an unusual display, sweeping the bill over the bark inside and outside the nest-hole. During this activity, the bill usually contains an insect, leading to speculation that the action might release an odour that deters predators.

[*Sitta carolinensis carolinensis*, near Waldorf, Maryland, USA.
Photo: George M. Jett]

The female **Eurasian Nuthatch** performs the bulk of the parental duties. She makes the final choice of nest-site, plasters the entrance hole and, with a modicum of help from her partner, builds the nest inside the cavity. Once she has laid the eggs, normally one per day, the female covers them with nest material—a form of behaviour that is rather rare among passerines. The female alone incubates the eggs for 13–18 days and broods the nestlings for three or four weeks. Both parents, however, feed the chicks, which means that the nest tree is usually the scene of constant activity, with adults coming and going.

ing site, are inaccessible, they may not leave the roost at all, spending over 40 hours in the cavity without food.

The behaviour of the Brown-headed Nuthatch, confined to the warmer south-east USA, contrasts markedly with that of its close relative. Either the female alone or both sexes of the Brown-headed Nuthatch may roost in the nest-cavity during the breeding season, but in the late summer, after the young have fledged, they either sleep in the open in the crowns of trees or return to sleep in cavities as a family party. This species has been found to roost communally in a nestbox, but only in very small numbers, just four individuals. The regular communal roosting of the Pygmy Nuthatch, which has to contend with winter temperatures of –40°C or lower, has not been recorded for this species.

One intriguing type of behaviour is exhibited by several species of nuthatch. This involves an individual suddenly falling silent and sitting motionless for several minutes, as if napping. At present, there is no explanation for this behaviour, the function of which remains entirely unknown.

Voice

Nuthatches are very vocal, but almost all of their vocalizations are simple and repetitive. These consist of a single note, or uncommonly two-note or three-note combinations, repeated at various speeds and for varying periods. Importantly, the distinction between calls and songs is not clear, and for many members of the family the utterance that equates to song is merely a louder and longer repetition of the call. In the case of the Eurasian Nuthatch only the males “sing”, usually while sitting upright and with the bill directed upwards. In Europe, this “song” is given from December to June, reaching a peak in April, at the start of laying, and thus has little or no role in the maintenance of territories, as these are established in summer and autumn, the period when song is most infrequent. The same matter of timing rules out the possibility that this vocalization has a major role in the pair-formation process, although males that lose a mate do sing more often. In short, the definition and role of song among nuthatches is far from clear.

A variety of calls is emitted by nuthatches, and detailed studies of the Eurasian Nuthatch and also of the North American

Sittidae have identified several context-specific vocalizations. For practical purposes, most calls can be categorized as relatively low-pitched, mellow whistles, often easily imitated by humans, and frequently given in series, sometimes as a trill and grading into “songs”. Higher and thinner vocalizations are often given as contact calls, and harsh calls are uttered in excitement. Some harsh calls are reminiscent of the warning scream made by a Eurasian Jay (*Garrulus glandarius*) and are often transliterated as “schraa”; on a sonagram they appear as broad, near-structureless smudges. Taxonomic significance has been accorded to the presence or absence of these jay-like alarm calls in a species’ vocabulary, especially in the “*S. canadensis* group”.

Pygmy Nuthatches, White-tailed Nuthatches and the two rock nuthatches have been recorded as duetting, but the degree to which this is widespread within the family has not been investigated. Nor has the significance of this behaviour been analysed in detail.

Food and Feeding

All nuthatches feed predominantly on insects and other small invertebrates, including snails (Gastropoda), but seeds and nuts can also be important in the diet, especially during the winter months. The stomach often contains grit, presumably taken as an aid to the digesting of hard-shelled seeds. As already mentioned (see Morphological Aspects), the typical nuthatch bill is well designed for the opening of acorns and hazelnuts, and these and other large seeds are eaten when available, but smaller seeds, such as those of beech and pine, are consumed more frequently.

With the exception of the two rock nuthatches, all members of the family forage on the trunk and larger branches of trees, although some, especially the smaller species, will also work through smaller twigs, clusters of conifer needles and cones. They find their food by sight or by probing with the bill, and will scale off pieces of flaky bark in order to examine the area beneath. Nuthatches are flexible, and will generally take anything edible that they come across; they usually break up large food items by wedging them into cracks or crevices and hammering them with the bill, but, unlike the woodpeckers (Picidae), they rarely hack into wood as a means of obtaining access to prey. They obtain

most of their food, at least animal items, by gleaning from the bark surface or probing among conifer needles and cones; they will also capture small invertebrates by aerial flycatching, although this is a less common strategy. Both techniques are used also by the rock nuthatches, which simply transfer the gleaning method to rock surfaces. Together with the tits and chickadees, the woodpeckers, the treecreepers and a few others, the nuthatches are members of the bark-foraging guild, sometimes known also by the term the pariform guild. Owing to their varied diet and their foraging methods, however, they are not so specialized as are other members of the guild, such as the woodpeckers and the treecreepers.

Outside the breeding season, nuthatches of all species appear to spend most of their time with mixed-species foraging flocks. Various studies have demonstrated that the foraging success of Eurasian Nuthatches is higher when these birds are members of a flock, probably because they benefit from having to spend less time in looking for predators and devoting more time to foraging.

Most species of nuthatch store food items, often covering them with lichen. They are "scatter hoarders", hiding items singly, as opposed to "larder hoarders", which store more than one item in a single cache. Cached items are mostly seeds and nuts, but insects, too, are sometimes stored for later retrieval. The behaviour of hoarding of food items reaches a peak early in the day, and slowly decreases as time goes on.

Three species of nuthatch, all North American, have been recorded as using tools. The Brown-headed Nuthatch has been observed to make use of a piece of bark as an extension of the bill, helping it to prise off other bark flakes. It usually drops its "tool" after removing a scale, but it may remove several scales before dropping it, or it may carry its tool from one tree to the next. The use of such foraging aids is most frequent in occurrence during years with a poor seed crop, and it has been suggested that the behaviour developed from the nuthatch's habit of wedging pine seeds into cracks in the bark while it hammers them open. There is a single record of tool use by the Pygmy Nuthatch, an individual of which worked along a branch while holding a 3-cm twig and probing the bark; when it found something, it dropped the twig and pecked at the object that it had located. Finally, and although not in connection with foraging, the Red-breasted Nuthatch sometimes uses a small piece of bark as a "spatula" with which to apply tree resin to its nest-hole entrance.

Breeding

The Eurasian Nuthatch and probably most other members of the family are monogamous, and the partners of each pair remain together on territory throughout the year. New pairs can be formed at any time, but especially in early summer, and thus "song" (see Voice), which in the case of this species reaches a peak in April, does not play a major role in pair formation. Breeding activity starts in early spring, both sexes prospecting for suitable nest-sites.

All nuthatches are cavity-nesters. Most species use holes in trees, either excavating their own or using pre-existing holes. The latter include both natural holes and those excavated by another species, usually a woodpecker, thereby making the nuthatches "secondary cavity-nesters". Nests are placed at various heights above ground, and it seems that, although the availability of suitable holes clearly affects the selection, higher nests are less likely to be preyed on and are preferred. An exception to this general rule is provided by the Brown-headed Nuthatch, which usually excavates its own nest-hole, typically 1–2 m above the ground. As a comparison, the closely related Pygmy Nuthatch likewise excavates its own hole in about 40% of cases, but usually more than 5 m from the ground.

The smaller nuthatches, both those in the "*S. canadensis* group" and the "dwarf nuthatch" superspecies formed by the Pygmy and Brown-headed Nuthatches, usually excavate their own nesting holes in soft, decayed wood, although they will take over an existing hole. This has its advantages, in that they are able to dig out a hole that is exactly the right size. As a consequence, they do not use "plaster" to reduce the size of the hole; the only suggestion that any member of these two groups do so is in the form of circumstantial evidence relating to the nest of the Algerian Nuthatch. Indeed, these groups do not use mud in the nest at all, with the possible exception, again in the form of circumstantial evidence, of the Algerian Nuthatch and, in this instance, also for the Chinese Nuthatch. The male of the latter species brings mud to the female during the incubation phase, and she then utilizes this as a means with which to "repair" the interior wall of the nest-hole. In an interesting parallel, the Pygmy and Brown-headed Nuthatches use ordinary nest material when repairing such cracks.

So far as is known, no other nuthatches excavate their own nest-holes, although the data are insufficient to rule out this behaviour completely, particularly for many of the Oriental nuthatches. Again so far as is known, most of these species reduce the size of the entrance by applying a plaster-like substance made from mud. This plaster is often described as setting to a "terracotta hardness", and that made by some species includes other ingredients, such as dung, rootlets, moss, berries, saliva and, in the Indian Nuthatch, notably, tree resin. The use of such plaster is surely an anti-predator device, as well as reducing nest-hole competition by making the cavity unsuitable for larger birds that may otherwise usurp it. In Europe, both the Common Starling (*Sturnus vulgaris*) and the Great Spotted Woodpecker (*Dendrocopos ma-*

Once **Western Rock Nuthatches** have chosen a rock face or similar artificial structure as the location for their nest, the male sets about building what, for a sittid, is an astonishing construction. The male gathers material such as mud, animal dung and hair, and moulds it all into the shape of a flask, which hardens as it dries. The entrance tunnel may be as much as 10 cm long, and the diameter is just sufficient for the adults to squeeze in and out—but too narrow for most predators to do so. Such security measures give the Western Rock Nuthatch the confidence to locate its nest lower than those of arboreal sittids, sometimes as little as 2 m above the ground. This species sometimes adds decorative objects to the exterior of its nest, inserting them in nearby rock crevices. Nests are sufficiently sturdy to last from one year to the next, and indeed may be used by pairs for several successive breeding seasons. In line with the close relationship between the two species, the nest of the Eastern Rock Nuthatch (*Sitta tephronota*) is similar. However, the Eastern sometimes excavates its own hole or uses the old nest hole of a bee-eater (*Meropidae*), roller (*Coraciidae*) or woodpecker (*Picidae*).

[*Sitta neumayer zarudnyi*, Skala Kalloni, Lesvos, Greece.
Photo: C. Knights/Ardea]

This adult **Krüper's Nuthatch** has returned to the nest-site with a single caterpillar. Breeding in the summer enables temperate species of nuthatch to feed their young with invertebrates. Indeed, Krüper's Nuthatch is one of many sittids that provisions its nestlings solely with such animal matter. This is slightly surprising, given that this small nuthatch is closely tied to Turkish pine (*Pinus brutia*), and that several such sittids specializing in coniferous forests also feed their offspring with pine seeds. Krüper's Nuthatch chicks are brooded by the female, but fed by both parents.

[*Sitta krueperi*,
Lesvos, Greece.

for) are important nest predators, although the woodpecker is capable of smashing its way into a plastered hole.

When disturbed while sitting on the nest, females of the Eurasian Nuthatch have no specific anti-predator display, but otherwise can be vigorous in defence of the nest, even attacking a woodpecker. In the face of predators, the White-breasted Nuthatch performs a distraction display in which it assumes a moth-like pose, with the body and bill held upright and the wings and

tail fully spread; in this posture, the bird sways slowly from side to side, at the same time fluffing out the white ear-coverts, which, when the nuthatch is viewed from behind, look like huge eyes. A very similar display has been recorded for the Eurasian Nuthatch, when presented with a stuffed woodpecker, and for the Red-breasted Nuthatch. In response to the climbing of the nest tree by American red squirrels (*Tamiasciurus hudsonicus*), the incubating female Pygmy Nuthatch sometimes jumps out of the cavity and perches at the entrance, facing down towards the squirrel, and, with the wings spread, holds her body in a fixed position and sways slowly from side to side in a rhythmic movement. This seems to have the desired effect, as the squirrel freezes, fixated on the nuthatch for up to 10 seconds, before retreating.

The Eurasian Nuthatch, the best-studied member of the family, is probably typical of many nuthatches in its nesting behaviour. The final choice of nest-site is probably made by the female, and she also undertakes the work of plastering the hole and building the nest, tasks which are carried out over a period of 2–4 weeks, plastering continuing even after the eggs have hatched. At the beginning the male takes little part, merely providing some nest material, but his share of provisioning increases once laying has commenced, and in the later stages he may even participate in the plastering work. Mud and clay are brought in pellets and hammered into shape around the entrance, the bill being used for this work. The nest of the Eurasian Nuthatch consists of a foundation of wood chips, sufficient to fill over-large cavities, which is surmounted by bark flakes, usually of pine, rarely incorporating dry leaves, lichen, conifer needles and the like. It has been suggested that a preference for bark flakes reflects the anti-parasite properties of such material, and the birds may have to travel some distance in order to obtain them. The nest of the Brown-headed Nuthatch, a pine specialist, is sometimes made largely of pine-seed wings, but that of the Pygmy Nuthatch, another pine specialist but living in cooler climes, includes a greater amount of insulating material.

Among the numerous tree-nesting species, the Kashmir Nuthatch produces what may be the most elaborately plastered nests. In up to 33% of these the plaster forms a short cone, occasionally extending also for some distance around the hole. This process is taken even further by the rock nuthatches. The Eastern Rock Nuthatch's nest is a flask-shaped structure, usually built over a crack,

Clutch size in the **Eurasian Nuthatch** is within the range 4–13, but is normally towards the lower end of this scale.

Even having just a few chicks places a significant responsibility on the adults to provide sufficient food.

Adults must also avoid unwittingly revealing the nest location to potential predators. It follows that there are advantages for an adult in returning to the nest with as much food as it can carry in its bill, rather than making more journeys with fewer items. The species mainly feeds its young with beetles (Coleoptera) and caterpillars (Lepidoptera).

[*Sitta europaea europaea*,
Estonia.

Although female nuthatches lay their eggs each a day apart, the brood hatches within a more condensed timeframe, normally just 24 hours. This roughly equal starting time increases the likelihood of the chicks growing at a similar rate, which, in itself, increases the chances of the entire brood fledging. Nestling **Eurasian Nuthatches** grow somewhat more slowly than most other passerines, perhaps because the secure nest-hole reduces the necessity of rapidly acquiring the ability to fly. Nestlings are hatched naked, and feathers do not appear for three days. The chicks' eyes remain closed until they are nine days old, and the remiges do not emerge until a fortnight has passed. By this time, the brooding stint has declined to five minutes per hour, compared with 25 minutes per hour around hatching time. Thereafter, development is more rapid, and the offspring may leave the nest after 4–11 further days. The fledglings remain dependent on their parents for one or two additional weeks. In those sittids for which data are available, breeding success tends to be high. Two-thirds of Eurasian Nuthatch eggs laid lead to successful fledging, while the average number of fledglings can be as high as 5.5 per pair. Nest failures are usually due to the incumbent sittids being ousted by a larger cavity-nester, or due to nest predation. In both instances, squirrels (*Sciuridae*) and woodpeckers (*Picidae*) are often responsible.

[*Sitta europaea caesia*,
Pyrenees, France.
Photo: Dave Watts]

Nest sanitation is an essential part of sittid parental responsibilities.

Like other passerines, nuthatch nestlings excrete their faeces inside white, gelatinous sacs. This adult **Eastern Rock Nuthatch** is transporting a faecal sac a safe distance from the nest. In the well-studied *Eurasian Nuthatch* (*Sitta europaea*) and *Pygmy Nuthatch* (*S. pygmaea*) at least, adults tend to smear faecal sacs on branches, thereby destroying rather than merely discarding them. When the chicks are very young, the adults swallow the faecal sacs, as they retain significant quantities of nutrients because of the chicks' inefficient digestion.

cavity or hole in a rock face, a tree or even a building. The hole may be natural, or the abandoned hole of a bee-eater (*Meropidae*), roller (*Coraciidae*) or woodpecker, or it may have been excavated by the birds themselves. The entrance is walled up with plaster, leaving just a small hole or a short conical entrance tunnel 45–150 mm long. The “plaster” is a mixture of mud, saliva, excrement, resin, feathers, hair, cloth, insect fragments, and even such artefacts as sweet-wrappers, and, when a tree hollow is used,

the interior of this is often lined with mud. Nests of the Western Rock Nuthatch are almost always placed on a rock face or building, and they have a longer entrance tunnel than those of Eastern Rock Nuthatches. Both rock nuthatches will often decorate the vicinity of the nest with a variety of objects, both natural and man-made.

An anti-predator tactic employed by the White-breasted Nuthatch, and reported also for the White-cheeked Nuthatch, is a bill-sweeping display. In this, the bill is swept backwards and forwards in an arc over bark near the nest-hole, sometimes for several minutes. The inside of the nest-cavity may also be “swept” in this way, and during the sweeping process an insect is usually held in the bill, although sometimes fur or vegetation is used, and sometimes the bill alone is used. The presence of squirrels may precipitate sweeping, and the purpose of this action may be to use the odours from the objects being swept as a means of confusing squirrels, which are potential predators and competitors for holes.

The Red-breasted Nuthatch employs a different technique to deter predators. It smears the entrance to its hole with the sticky resin, often known as “pitch”, that is exuded by conifers. Both male and female bring globules of resin on the tip of the bill throughout the incubation and nestling stages, sometimes at a rate of 5–10 applications per hour. The species has even been recorded as using a small piece of bark with which to apply the substance, this being the only known example of the use of a “tool” by this species. There are clearly risks attached to this strategy, as nuthatches have on rare occasions been found dead, trapped in this gum. Red-breasted Nuthatches have developed several ways of minimizing the risk. A notable example is that they avoid the pitch by flying straight into the nest at high speed, sometimes after hovering in front of the entrance, and the nestlings, after having fed, turn around to deliver their faecal sacs at a point where the adult can reach them without needing to enter the cavity. When the young are about to leave the nest, the entrance floor is covered with litter or fur, presumably to neutralize the pitch and ensure safe passage for the young.

Copulation is seldom observed, even for the well-studied *Eurasian Nuthatch*. The female of this species solicits by crouching, shivering her wings and moving her head from side to side in what is known as the “pendulum display”. This is matched by

Sittid parental care continues after the young have fledged. In the **White-breasted Nuthatch**, adults continue to feed the chicks for a full fortnight, during which family parties wander around their territory. These forays risk bringing the uninitiated fledglings into contact with avian predators such as raptors; mortality rates can be high. Should an adult White-breasted Nuthatch spot a predator, it may perform a distraction display. Adopting an erect, moth-like pose, it sways from side-to-side and extends its white ear-coverts outwards, in such a way that they resemble huge eyes when viewed from the rear.

the male, but in an upright posture, facing away from the female, and after up to 30 seconds the male turns, with the bill still pointed upwards, and mounts the female. This process may be repeated several times. Similar pendulum displays are described for several nuthatches, one such being the Pygmy Nuthatch. Courtship feeding by the Eurasian Nuthatch starts a few days before laying commences.

Eggs are laid in the early morning, normally one per day, clutches typically varying from four eggs to eight eggs. The eggs

of the Sittidae are white, variably marked with reddish, brown and lilac spots, these normally being concentrated at the broader end. Mean egg weights vary with body size, even within a species, those of the Eurasian Nuthatch varying from about 1.8 g in the subspecies *asiatica* to 2.2 g in the somewhat larger nominate race; the mean weight of eggs of the tiny Pygmy Nuthatch in California is 1.2 g. The Eurasian Nuthatch covers the eggs with nest material throughout the laying and incubation stages. This is an unusual habit among passerines, but the nuthatch's nest usually fills the cavity, with its top almost at the same level as the entrance tunnel, and the eggs and, later, the nestlings are therefore clearly visible through the hole. The Pygmy Nuthatch similarly covers the eggs, and this behaviour may be common in the family. Incubation usually starts after the last egg is laid, but it may be delayed, especially in bad weather. It appears that, for all members of the family for which the relevant information is available, only the female incubates, although she is fed on and off the nest by the male. The female Eurasian Nuthatch spends 20–30 minutes on the nest, followed by a break of about 10 minutes; thus, she sits for two-thirds to three-quarters of her time during the incubation stage. On returning to the nest, she turns in half-circles until all of the covering nest material has been moved aside.

Rather few data are available on the duration of the incubation period, and for the majority of the family there is no information at all on this aspect of the breeding biology. The Eurasian Nuthatch incubates for 13–18 days, and this range seems to be fairly typical for the family, as a period of 12–17 days has been recorded for the much smaller Pygmy Nuthatch. All the eggs hatch usually within a period of 24 hours. At nests of the Eurasian Nuthatch the female breaks the remains of the eggshells and eats them, but in the case of the Pygmy Nuthatch the two parents remove shells from the nest and deposit them more than 30 m away. After the eggs have hatched, the female spends up to a third of her time in brooding the nestlings, but this decreases to a few minutes per hour in the days immediately before the chicks fledge. The young are fed by both sexes, often entirely with animal matter, but some of the small conifer specialists provision the young with seeds, too. Large food items are not broken up, and the White-breasted Nuthatch has been recorded as feeding its nestlings with dragonflies that have the wings still attached.

Six nuthatches officially qualify as restricted-range species, with a distribution of 50,000 km² or less, and a few taxa recently elevated to species level may join them once they have been formally assessed. One restricted-range species is the **Kashmir Nuthatch**, which occurs only in the Western Himalayas Endemic Bird Area. This species inhabits coniferous, mixed and deciduous forest at altitudes of 1800–3500 m. The species is generally quite common throughout its range so, despite forest loss, degradation and fragmentation in the region, it is not considered to be globally threatened.

[*Sitta cashmirensis*, Chitral Gol National Park, North West Frontier Province, Pakistan. Photo: Menno Hornman]

The **Corsican Nuthatch**, **Red-breasted Nuthatch** (*Sitta canadensis*) and **Chinese Nuthatch** (*S. villosa*) are three superficially similar species that have often been considered to form a single species, despite occurring huge distances from each other. Such treatment is all the more remarkable given that the Corsican Nuthatch is endemic to a single Mediterranean island. A restricted-range species, endemic to the Corsican Mountains Secondary Area, it favours old-growth Corsican pine (*Pinus nigra*) forests with plentiful dead wood. Populations are stable, so the species is thought not to be at risk of extinction.

[*Sitta whiteheadi*, Gorges de la Restonica, Corsica. Photo: Mike Read]

Being almost entirely dependent on forests and often having small ranges, it is perhaps predictable that a quarter of sittids are under some threat of global extinction. Four species are globally threatened and three Near-threatened, the latter including the **Yunnan Nuthatch**. This restricted-range species occurs only in the Yunnan Mountains Endemic Bird Area. Although still locally common, a continuing population decline has resulted in several local extinctions. If, as feared, the Yunnan Nuthatch needs mature pines (*Pinus*) for nesting, the security offered by its toleration of degraded forest would be reduced.

The adult Eurasian Nuthatches swallow the chicks' faecal sacs for the first four days, and thereafter carry away the larger sacs and also soiled nest material, often smearing it on branches, rather than dropping it at random. Similarly, the Pygmy Nuthatch parents initially consume the faecal sacs but, from 2–3 days after the hatch, both they and, when present, the helper remove the sacs and deposit them on a high limb, wipe the bill, and rap it vigorously on the branch, frequently using the same limb for this purpose.

Nestlings have long, scanty down; the interior of the mouth is fleshy-coloured or yellowish, and there are no tongue spots. Nestlings of the Eurasian Nuthatch develop rather slowly compared with those of many similarly sized passerines. The nuthatch chick exhibits the first traces of feathers on day 3, the eyes open on day 9, the first feathers emerge on day 9, and the first flight-feathers emerge from their sheaths on day 14; the chicks leave the nest after 18–25 days. In the Brown-headed and Pygmy Nuthatches, rather smaller species with a slightly shorter fledging period, the sheaths for all the feather tracts appear on days 6–9 and the eyes begin to open on about day 7, while the primary sheaths of the nestling Pygmy Nuthatch begin to break at 8–10 days. The security of a hole nest may facilitate this slow development. Indeed, for the few species for which good data are available, nesting success is fairly high; in studies of Eurasian Nuthatches, for example, the number of fledged young produced per pair varied from 2.9 to 5.5, at least 66% of eggs laid being successful. The commonest causes of nest failure are probably takeovers by other cavity-nesters or predation, with squirrels and woodpeckers the main culprits; for the poorly known tropical species of nuthatch, snakes may also be significant nest predators. In the face of failure, nuthatches will sometimes lay repeat clutches, but true second broods appear to be rather rare.

At nests of Pygmy Nuthatches, some nestlings, one or two days before fledging, may creep 15–20 cm out from the nest entrance, but they remain outside the cavity for less than one minute. This exploratory behaviour has not been recorded for any other members of the Sittidae. For the first few days after leaving the nest, juvenile nuthatches spend much time in sitting in a well-concealed position in the canopy, waiting to be fed. As they mature, the family party roams more widely, sometimes beyond the

Conservationists are keeping a close eye on the **Yellow-billed Nuthatch**, which is listed as Near-threatened. The distribution of this restricted-range species extends over parts of the Endemic Bird Areas of Hainan and Da Lat Plateau, as well as the Fan Si-Pan and Northern Laos Secondary Area. The population on Hainan (*race chianfengensis*) was discovered as recently as 1963 and is endemic to the island. Its survival here is far from assured, as the island's forest cover declined by 72% between 1949 and 1981, when just 7% of the total land area remained forested.

Holmes]

territory boundaries. Mortality at this stage is high, many young falling victim to avian predators. Young Eurasian Nuthatches cease being fed about 10–11 days after fledging, and they probably disperse quickly.

Nuthatches usually attempt to breed when one year old, although some year-old males of the Pygmy Nuthatch and the Brown-headed Nuthatch are merely helpers at nests of other pairs. These two species, incidentally, appear to be unique among the Sittidae in being co-operative breeders. Approximately 10–60% of breeding pairs of Brown-headed Nuthatches have helpers, most of which are year-old individuals; these helpers are almost always males and all are related to the breeding pair, usually to the male partner. In studies of two colour-marked populations of Brown-headed Nuthatches in Florida, however, one case of a female assisting with the incubation of the eggs was recorded. Helpers may assist in chasing intruders from the territory, in excavating cavities, in providing nest material, in the task of nest sanitation and in feeding the female on the nest, as well as in provisioning the young, both as nestlings and as fledglings. They do not, however, roost with the breeding pair. In Pygmy Nuthatches, about 20–40% of nests have helpers, usually one but sometimes as many as three. Again, these assist with nest construction, nest sanitation, the feeding of the female on the nest during incubation and brooding and the feeding of the young, although the helper is sometimes driven away by the male of the pair during the laying period. Some helpers participate throughout the breeding cycle, whereas others arrive part-way through after their own breeding attempts have failed. Most help for a single year, although a few may assist the same breeding pair for a second year. Unlike the situation with the Brown-headed Nuthatch, helpers at Pygmy Nuthatch nests roost with the parents in the nest-cavity at all stages of the breeding cycle.

Notably, the presence of helpers does not increase the rate at which the young are fed but, rather, it reduces the number of feeding visits made by the parents and thus, presumably, reduces the stress placed upon them. This is thought to aid the adults' winter survival. For both Brown-headed and Pygmy Nuthatches helpers are clearly beneficial, and pairs with helpers are significantly more successful in fledging young than are those without. In the case of Pygmy Nuthatches, the presence of one or more helpers has the effect of reducing the number of nest failures, rather than increasing the number of young produced.

Movements

Almost all members of the family are resident, and juveniles, although they do disperse, seem to do so over short distances. Among Eurasian Nuthatches, for instance, most of the juveniles reared in good habitat move less than 1 km from where they hatched, with no difference between males and females, although in more fragmented habitats young may move 3–10 km before establishing their first territory or home range. A small minority go farther, but in Europe there are very few ringing recoveries made beyond 100 km. There is a rapid initial dispersal from the natal territory soon after fledging, in June and July, followed for a small minority of individuals by longer-distance movements, which reach a peak in August–September. Among Eurasian Nuthatches, long-distance dispersals are orientated mainly towards the south-west and are sometimes considered to be “irruptions”, with higher numbers and extralimital records more frequent in some years than in others. Those involving European populations appear to peak in years with high population densities but seem to reflect rather local conditions. In contrast, those of the “*asiatica* group” of subspecies from Siberia undertake similarly irregular movements, but involving populations from much larger areas and making longer journeys, variable numbers of individuals reaching Finland, often the Baltic countries and north Sweden, and sometimes Norway, too. These irruptions are probably due to the nuthatches’ dependence on the crop of cones of Siberian stone pine (*Pinus sibirica*), and, in years when the cone crop fails, thousands of Eurasian Nuthatches have been seen on the move in Siberia. In eastern Asia, the subspecies *amurensis* makes similar but less frequent irruptions, large numbers passing along the coast of Ussuriland. Even in such circumstances, however, the Eurasian Nuthatch, as all nuthatches, shuns water crossings, and there are very few records of vagrants from offshore islands. In western Europe, nuthatches may again disperse, presumably over short distances, in the early spring, and there is limited evidence that some Eurasian Nuthatches winter in areas where they do not breed, this perhaps reflecting the seasonal availability of food.

The Red-breasted Nuthatch of North America is also an irregular irruptive migrant, but its irruptions are much more frequent and more regular than are those of its Eurasian relative. The most northerly breeders, and those at the highest altitudes,

may fly south or move downslope every year. For the bulk of the populations, however, movements are dependent on the crop of conifer seeds, and they generally have a two-year cycle. In years with a good cone crop, the centre of gravity of the population moves only slightly southwards. In years of cone-crop failure, in contrast, there is a variable exodus from the breeding areas, and Red-breasted Nuthatches may reach southernmost California, the Gulf Coast and northern Florida.

In the Himalayas and south-west China, nuthatches breeding at higher elevations will undertake seasonal altitudinal movements, moving downslope in the colder months. In most cases, however, the extent of these movements is poorly known.

Relationship with Man

The name *Sitta* originates from the ancient Greek σιττη, transliterated as “*sitte*”, which was first used by Aristotle in his *Historiae Animalium* to refer to a bird that pecks at the bark of a tree. The word may possibly be onomatopoeic, and relate to the call of the Eurasian Nuthatch or, perhaps, the highly vocal Western Rock Nuthatch, the latter still a familiar and noisy bird at the sites of Greek antiquities. Whatever the truth may be, the word *Sitta* was chosen by Linnaeus, in his *Systema Naturae* of 1758, for the nuthatch genus. “Nuthack”, corrupted to “nuthatch”, describes the typical feeding action of the family.

Nuthatches are easily attracted to garden birdfeeders, where they readily take sunflower and other seeds, suet, bread and other items of food. Their lively, perky character makes them popular visitors. In some places, they become accustomed to the presence of humans and can be very approachable, soon becoming tame. In parks and cemeteries in parts of Europe, for example, nuthatches will readily take food from the hand, and it is possible for human beings to “call up” the birds by whistling and then to hand-feed them with seeds and similar items. In North America, the White-breasted Nuthatch likewise may become quite tame and fearless, taking food from people’s outstretched hands. Even some of the smaller nuthatch species in southern Asia will often allow a close approach.

From the point of view of conservation, the nuthatch provides positive associations in Europe with woodlands. In Ger-

Although the distribution of the **Giant Nuthatch** extends over a large area in south-west China, central and east Myanmar and north-west Thailand, its population is becoming increasingly fragmented. Fewer than 10,000 individuals are thought to remain, and the species is listed as *Vulnerable*. The pine (*Pinus*) forests inhabited by the Giant Nuthatch are being destroyed or degraded by commercial logging and exploitation for firewood. In addition, clearance for shifting cultivation has removed large areas of habitat, and uncontrolled burning is a further threat.

[*Sitta magna ligea*, Zixishan mountain, Chuxiong, Yunnan, China. Photo: Li liwei]

many, the Eurasian Nuthatch was selected as the "Bird of the Year" in 2006, awarded this title by the BirdLife partners in order to awaken among people an awareness of the conservation needs of natural woodlands with old trees.

Status and Conservation

Nuthatches are specialists, in that all except two species are closely tied to forest, both for feeding and for breeding. Furthermore, while several species are widespread and have vast, continent-wide ranges, as illustrated by the Eurasian and Red-breasted Nuthatches, a significant number have relatively small, even tiny ranges, indicating that in some way, as yet poorly understood, they are extreme specialists. Not surprisingly, a good proportion of the Sittidae, seven of the 27 species, have conservation designations. Four species are globally threatened and three are Near-threatened.

Two species, both having an extremely limited range, are categorized as Endangered. These are the Algerian Nuthatch, confined to the mountains of north-east Algeria, and the White-browed Nuthatch, restricted to Mount Victoria and surrounding mountains in west Myanmar. The Corsican Nuthatch has a similarly circumscribed range and a small population in Corsica, but its numbers are thought to be stable and it is therefore classified as of Least Concern.

Several other species have a limited distribution, although not with so tiny a global range as those of the aforementioned species, and many of these, too, are of conservation concern. The Giant Nuthatch and the Beautiful Nuthatch both have relatively small ranges centred around South-east Asia, and both are listed as Vulnerable, while Krüper's Nuthatch of Asia Minor, the Yunnan Nuthatch of south China and the Yellow-billed Nuthatch of Indochina and Hainan are currently considered Near-threatened.

The remaining species having a more or less restricted range are the Chinese Nuthatch of north China, the Kashmir and White-cheeked Nuthatches of the western Himalayas, the Sulphur-billed Nuthatch of the Philippines and the Blue Nuthatch of the Sunda Region. Although none of these five species is presently considered to be at any immediate risk, one or more of them could easily move into the Near-threatened category as their habitats continue to shrink.

[*Sitta formosa*,
Eaglenest Wildlife
Sanctuary, Arunachal
Pradesh, India.
Photo: Jimmy Chew]

The White-browed Nuthatch is endemic to a tiny area of just 820 km² in the southern Chin Hills of Myanmar. Some observers have found it to be fairly common, but others consider it sparsely distributed. Either way, its total global population appears to be under 10,000, and is probably declining. Within its range, no forest remains below 2000 m, and that at 2000–2500 m is heavily degraded. The combination of a small range, major threats and low population have led to the White-browed Nuthatch being classed as Endangered.

[*Sitta victoriae*,
Mount Victoria, Myanmar.
Photo: John & Jemi
Holmes]

With the exception of the two rock nuthatches, all members of the family are dependent on forest, with optimal conditions for all species likely to be primary forest with abundant large trees and standing dead wood. Throughout the world, these forests have declined sharply. This process started many centuries ago in Europe and eastern Asia, but habitat destruction has taken place much more rapidly in the Americas over the last 200 years and began in the Himalayas and western China even more recently.

In Europe and North America, populations of nuthatches have more or less stabilized and little recent change in their numbers is evident, although both the Brown-headed and the White-breasted Nuthatches appear to be in slow decline in the eastern USA. Insidious changes such as habitat fragmentation and degradation reduce the suitability of the remaining forests. As mentioned previously (see Habitat, Breeding), nuthatches nest in cavities and most of the species require older trees, and especially standing dead wood, in which many suitable holes exist or can be excavated. Modern forestry practices, however, generally do not take account of the needs of wildlife, and the removal of such trees is commonplace. This and other processes, which include the thinning of dense stands and selective felling, may now be having as much of an effect on the avifauna as does total forest clearance. In southern Asia, the main centre of diversity for the family, the situation is much more grave, and it seems likely that nuthatches will share the fate of most forest birds in that part of the world.

PLATE 3

inches 3
cm 8

Genus *SITTA* Linnaeus, 1758

1. Eurasian Nuthatch

Sitta europaea

French: Sittelle torchepot **German:** Kleiber **Spanish:** Trepador Azul
Other common names: (Common/Wood) Nuthatch; European Nuthatch (*europaea*); Southern Nuthatch (*caesia*); Chinese (!)/Oriental Nuthatch (*sinensis*); Hondo Nuthatch (*hondoensis*); Kamtschatkan Nuthatch (*albifrons*); Yesso Nuthatch (*clara*)

Taxonomy. *Sitta europaea* Linnaeus, 1758, Europe and America = Sweden.

Forms a superspecies with *S. nagaensis*, *S. cashmirensis*, *S. castanea*, *S. cinnamoventris* and *S. neglecta*; has often been treated as conspecific with some or all of these. Geographical variation complex. Races usually divided into three main groups, buff-breasted “*caesia* group” (in W Europe, N Africa and Middle East), white-breasted “nominate group” (N Palearctic from Scandinavia E to Japan, S to E Tien Shan and N China), and buff-breasted “*sinensis* group” (C & E China), with large race *arctica* (NE Siberia) as a separate “group”; recent detailed morphological studies of Asian populations, combined with examination of mitochondrial DNA (mtDNA) from many localities across range (but excluding Turkey, the Levant, Iran and China), have revealed a more complex situation, but details not yet resolved. Present treatment tentative, based on incomplete molecular-genetic material: European “nominate group” (now including “*caesia* group”), within which mtDNA reveals a European clade, as well as a separate clade based on individuals of race *caucasica* (but other Middle Eastern populations not sampled and limits of Caucasian grouping impossible to define, hence provisionally combined with European clade); Asian “*asiatica* group”, comprising white-bellied N forms and buff-bellied SE forms, which shown by mtDNA to form a natural grouping (although birds from Hokkaido, in N Japan, differed by c. 1% uncorrected mtDNA, and some or all of Japanese forms may represent a distinct subgroup); “*sinensis* group” of China (no DNA data); NE Asian *arctica*, which differs significantly in mtDNA from all other races and may well represent a separate species (several reports of its occurring sympatrically with “*asiatica* group”). Also, “nominate group” meets or overlaps with “*asiatica* group” in two small areas (S Urals, and lower basins of R Kama and R Vyatka), with hybridization reported as limited and not significantly affecting the phenotype of adjacent “pure” populations; these two groups possibly represent distinct species. In addition, nominate race and *caesia* intergrade over broad front from E Denmark E to Lithuania and W Belarus and S to W Ukraine, E Bulgaria and NW Turkey; birds in N Turkey are intermediate between *caucasica* and *caesia/levantina*; race *amurensis* intergrades with *baicalensis* in Amur valley (SE Russia) and with *sinensis* in relatively narrow zone in NE Hebei (E China). Birds of this species in Altay region of N Xinjiang (NW China) of uncertain racial identity, provisionally included in *seorsa*. Races *baicalensis*, *sakhalinensis*, *clara* and *takatsukasai* often merged with *asiatica*, and race *formosana* often synonymized with *sinensis*. Twenty-two subspecies currently recognized.

Subspecies and Distribution.

S. e. caesia Wolf, 1810 – W Europe from Britain E to Denmark, Poland and W Belarus, S to N Spain (Cantabrian Mts and Pyrenees), Alps, Balkans (except Dalmatian coast), Greece and W Turkey (Thrace and NW Anatolia).

S. e. europaea Linnaeus, 1758 – S Scandinavia (including most islands in S Baltic) and W Russia (E to Volga and Vyatka basins) S to E Poland, E Romania, E Bulgaria, NW Turkey (N Thrace) and Ukraine.

S. e. hispaniensis Witherby, 1913 – Portugal, C Spain and N Morocco (Middle Atlas and C High Atlas).

S. e. cisalpina Sachtleben, 1919 – Switzerland (S of Alps), Italy, N Sicily, coastal Croatia and SW Montenegro.

S. e. levantina E. J. O. Hartert, 1905 – S Turkey (SW Anatolia E to E Taurus).

S. e. persica Witherby, 1903 – extreme SE Turkey, N Iraq (Kurdistan) and W Iran (Zagros Mts S to Fars province).

S. e. rubiginosa Tschusi & Zarudny, 1905 – SE Transcaucasia (Talyshskiy Gory Mts and Lenkoran area) and N Iran (Elburz and Caspian districts E to extreme NW Khorasan).

S. e. caucasica Reichenow, 1901 – NE Turkey, SW Russia (in Caucasus S from basins of Terek and Kuban), Georgia, Armenia and Azerbaijan.

S. e. asiatica Gould, 1835 – C Russia (W foothills of middle Urals E to C Siberia and W shore of L Baikal) S to N & NE Kazakhstan (S to Kokchetau and Tarbagatay Mts) and W Mongolian Altai.

S. e. arctica Buturlin, 1907 – C & NE Siberia from Yenisey basin and Yakutia E to Anadyrland, upper R Penzhina and NW Koryak Highlands.

S. e. baicalensis Taczanowski, 1882 – E Siberia from W Yakutia (Vilyui valley) and L Baikal E to Sea of Okhotsk and N Amurland, S to Transbaikalia, C Mongolia and NE China (NE Nei Mongol and NW Heilongjiang).

S. e. albifrons Taczanowski, 1882 – NE Russia (S Koryak Highlands and Kamchatka Peninsula) and N Kuril Is (Paramushir).

S. e. amurensis Swinhoe, 1871 – Russian Far East (S & E Amurland, Ussuriland), NE China (N Heilongjiang S to NE Hebei) and Korea.

S. e. sakhalinensis Buturlin, 1916 – Sakhalin I.

S. e. takatsukasai Momiyama, 1931 – SC Kuril Is (Urup, Iturup).

S. e. clara Stejneger, 1887 – S Kurils (Kunashir, Shikotan) and N Japan (Hokkaido).

S. e. hondoensis Buturlin, 1916 – C & S Japan (Honshu, Shikoku and N Kyushu).

S. e. roseilla Bonaparte, 1850 – extreme S Japan (S Kyushu).

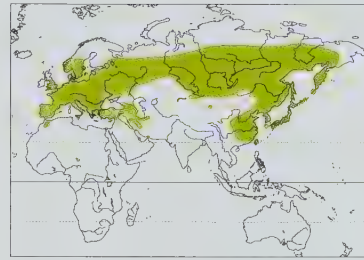

S. e. bedfordi Ogilvie-Grant, 1909 – Cheju I, off S Korea.

S. e. seorsa Portenko, 1955 – N & E Xinjiang (Altay region, in Altai Mts; Hami, in extreme E Tien Shan), in NW China.

S. e. sinensis J. Verreaux, 1870 – E China from S Gansu E to Shanxi, Beijing and NE Hebei, S to C Sichuan (to Wanyuan and W border of Red Basin), Guizhou, N Guangxi, Hunan, Jiangxi and Fujian.

S. e. formosana Buturlin, 1911 – Taiwan.

Descriptive notes. 14 cm; 17–28 g. Medium-sized nuthatch. Male nominate race has crown and upperparts blue-grey, black eyestripe; upperwing-coverts blue-grey, inner webs of greater coverts

dark grey; flight-feathers, primary coverts and alula dark grey-brown, secondaries, inner primaries and primary coverts fringed blue-grey (fringes widest on inner secondaries); central pair of tail feathers dull blue-grey, remainder blackish with blue-grey tip (broadest on outermost), outer three pairs with white subterminal spot on inner web and sometimes extending as bar across outer web (especially on outermost pair); throat and underparts off-white or creamy, with extensive deep rufous on flanks, lower vent and side of undertail-coverts, pale centres of undertail-coverts forming mottled patch; underwing grey, under

primary coverts black, contrasting white bases of primaries; in worn plumage, upperparts duller and not so blue, rufous on underparts slightly paler; iris brown to blackish-brown; stout and moderately blunt bill dark grey, darkest on culmen and tip, base of lower mandible bluish-white or horn-grey; legs greenish-yellow to pale brown or dark grey. Female is very similar to male, but often slightly paler above, eyestripe somewhat browner (less black), and underparts usually lightly washed buff, with rufous of flanks to vent strongly tinged buff. Juvenile resembles adult (especially adult female) but upperparts slightly duller, with faint brown cast and sometimes paler feather centres (especially on forehead), eyestripe duller, slightly browner and less well defined (especially female), also slightly duller below; base of bill pale bluish, legs generally paler than adult. Races differ mainly in plumage coloration, especially of underparts, also in size: *caesia* has cheek, ear-coverts and throat white, tinged buff, merging into dull orange-buff or cinnamon-buff on underparts, with flanks and rear vent deep rufous or brick-red, side of belly and anterior vent streaked chestnut, undertail-coverts whitish with broad deep rufous fringes and very narrow rufous tips (tips sometimes absent); *hispaniensis* is very similar to previous, but underparts paler (pinkish-cinnamon or pinkish-buff), flanks more contrasting, also smaller, with bill on average slightly more slender and pointed; *cisalpin*a also is very similar, but underparts brighter, more orange-buff or orange-cinnamon (less brownish-buff), bill on average shorter and more slender and pointed; *levantina* is poorly differentiated, as *hispaniensis* but underparts more pinkish (less buff), flanks slightly paler and less contrasting, upperparts on average slightly paler grey (especially in SE), often with faint white forehead, bill slender, culmen almost straight; *persica* is smaller than previous, differs also in having upperparts paler grey, white forehead and supercilium always present and better marked, underparts creamy with yellow-ochre wash, bill relatively short, very slender and attenuated; *caucasica* is rather small, has upperparts dark grey, forehead often whitish, underparts bright orange-tinged cinnamon-buff, bill short, thick and blunt; *rubiginosa* resembles last, but upperparts darker and more slaty, underparts on average paler orange-buff, usually lacks white forehead and supercilium, has less white in tail, bill slightly longer; *asiatica* resembles nominate but rather smaller, bill shorter and sharply pointed, culmen only gently downcurved, forehead and supercilium white (especially in E populations), upperparts slightly darker, in fresh plumage greater coverts tipped white (distinct wingbar), underparts white, chestnut of flanks to vent rather more restricted, female belly often washed buff and undertail-coverts paler rufous; *baicalensis* is slightly larger, with slightly longer bill and darker upperparts, but white forehead and supercilium reduced or absent; *sakhalinensis* is much smaller than last, upperparts somewhat less dark, white forehead fairly prominent, bill short (on average, shorter than all other races), near-straight culmen giving distinct upturned appearance; *clara* is larger than *asiatica*, bill shorter and more conical (culmen more noticeably curved), upperparts paler, white forehead and supercilium more pronounced; *takatsukasai* is as previous, bill similarly conical in shape but larger (most massive bill of all races), upperparts similarly pale but not so bluish, white tail spots larger, white forehead and supercilium bolder, belly of both sexes pure white; *albifrons* is large and pale, bill long and slender, culmen nearly straight, upperparts slightly paler than previous, slightly less white in tail, belly of female faintly or not at all washed buff; *amurensis* is large (largest Asian race apart from *arctica*), bill massive with gently curved culmen, upperparts relatively dark (slightly darker than *baicalensis*), white of forehead and supercilium faint or absent, no pale tips on greater coverts (unlike preceding six races), white of throat and breast grading to cinnamon-buff on belly (but nearly white in Sikhote-Alin Range); *hondoensis* is similar to last, but slightly paler and bluer above, white of forehead and especially supercilium more prominent, belly paler (pale pinkish-buff), bill only slightly smaller; *roseilla* also is similar, but upperparts rather darker, lower breast and belly more rufous-tinged brownish-buff; *bedfordi* is as previous, but throat and breast whiter and belly contrastingly darker orange-buff; *seorsa* is pale, bill and upperparts as *asiatica* but slightly larger, white of forehead and supercilium more prominent, belly pale buff; *sinensis* has bill medium-long with strongly decurved culmen, male throat and underparts pale cinnamon-buff, grading to white on chin, and whitish on cheek and below eye, side of neck slightly richer and brighter orange-buff, rear flanks brick-red with slight orange wash (contrasting with rest of underparts), feathers of undertail-coverts rufous with grey base and off-white shaft streak, streak broadening at tip (appearing as white inverted triangle), female as male but chin and cheeks lightly washed buff, rear flanks rufous-orange (little contrast with rest of underparts), undertail-coverts rufous-orange (paler than male and contrasting less with vent), both sexes in worn plumage slightly duller below (more cinnamon, even hint of drab-grey wash) and cheek and chin not so pure white, some variation (populations at higher elevations slightly larger, with greyer underparts); *formosana* is like last but slightly smaller, with longer, thinner bill, upperparts much paler, forehead and supercilium whitish, underparts slightly paler; *arctica* is large (largest Asian race), wing more pointed, tarsus and toes short (but hind claw rather long), bill slender with straight culmen (appears upturned with sharply pointed tip), plumage dark blue-grey above, black eyestripe narrower and shorter than in all other races, white of forehead and supercilium reduced or absent, much more white in tail (outer two rectrices mostly white), breast and centre of belly white, flanks extensively chestnut, undertail-coverts cinnamon with white tips, underwing-coverts dark grey (pale in all other races), sexes similar. VOICE. Very vocal, with loud piping and trilling calls. Commonest call, used in excitement, an abrupt, liquid whistled “twit” or “dwip”, singly or sometimes in slow sequence, more usually in couplets (“dwip-dwip”) or groups of 3–4 notes in quick succession (“dwip-ip-ip”), but in great excitement at up to c. 10 notes per second; also gives shrill, sibilant, almost trilling “sirrrr” or “tsi-si-si”, becoming harsher “sirrrp” in excitement or alarm, and cat-like “meeu-meeu” or “neu-neu”, and in extreme agitation harsh “trah”; contact call a high-pitched, thin “tsit” or “seet”, often just prior to taking flight; other calls include very high, thin, lisping “tsee-tsee-tsee...”. Song rather variable, a repetition of rising or falling or

On following pages: 2. Chestnut-vented Nuthatch (*Sitta nagaensis*); 3. Kashmir Nuthatch (*Sitta cashmirensis*); 4. Indian Nuthatch (*Sitta castanea*); 5. Chestnut-bellied Nuthatch (*Sitta cinnamoventris*); 6. Neglected Nuthatch (*Sitta neglecta*); 7. White-tailed Nuthatch (*Sitta himalayensis*); 8. White-browed Nuthatch (*Sitta victoriae*); 9. Pygmy Nuthatch (*Sitta pygmaea*); 10. Brown-headed Nuthatch (*Sitta pusilla*); 11. Corsican Nuthatch (*Sitta whiteheadi*); 12. Algerian Nuthatch (*Sitta ledanti*); 13. Krüper’s Nuthatch (*Sitta krueperi*); 14. Chinese Nuthatch (*Sitta villosa*); 15. Yunnan Nuthatch (*Sitta yunnanensis*); 16. Red-breasted Nuthatch (*Sitta canadensis*).

up-and-down notes, from 3-6 drawled penetrating whistles slowly repeated at c. 2 per second, e.g. "pee-pee-pee...", "ueeh ueeh ueeh..." or "weeu weeu weeu...", to rapid trill of up to at least 32 notes at rate of as many as 19 per second, "wiwiwiwiwiwi..."; many intermediate variants, and "song" may intergrade with repetitions of excitement call. Song of race *arctica* reported as being distinctly different, but no details available.

Habitat. Favours mature forest with large old trees and well-developed canopy providing extensive foraging areas, as well as nesting cavities. In much of Europe, deciduous and mixed forest, especially oak (*Quercus*), but found also in riverine woodland, parkland, old orchards, cemeteries, and sometimes large gardens (although requires minimum territory size of c. 1 ha of good-quality habitat, so generally absent from small stands of trees); locally in old spruce (*Picea*) and pine (*Pinus*) forests, especially in mountains. Similar habitats occupied in Far East, but favours pine forest in Taiwan; in Morocco found in oak forest, as well as fir (*Abies*) and cedar (*Cedrus*). In European Russia and throughout much of range in Siberia also in coniferous woodland, even quite stunted larch (*Larix*) forest in forest-tundra zone, but at very low densities. Outside breeding season wanderers may occur in riverine thickets, orchards and shelter-belts in steppe zone, and noted among dwarf junipers (*Juniperus*) at least 50 km from nearest woodland in W Mongolia, and in rocky terrain in Sayan Mts of S Siberia. Generally in lowlands in N parts of range, but in S Europe extends to tree-line in Switzerland (uncommon above 1200 m), to 1500 m and exceptionally to near tree-line at 1800–2100 m in Austria, and to 1200 m in Czech Republic; 300–1800 m in Turkey, to 1800 m in Caucasus (where favours mixed forest), to at least 1830 m in N Iraq and 2225 m in SW Iran, and at 1000–2200 m in Morocco; up to 2200 m in Altai and N Mongolia; in Japan primarily montane, in C Honshu at 760–2400 m and on Shikoku at 1370–1525 m, but at c. 300–1300 m in N Honshu and from sea-level to c. 915 m (Mt Daisetsu) on Hokkaido; montane also in Taiwan, where recorded at 800–3300 m, and to at least 2000 m in NE China; but confined to low and moderate altitudes in SW China (where replaced at higher levels by *S. nagaensis*).

Food and Feeding. Feeds on insects, especially beetles (Coleoptera) and lepidopteran caterpillars, and other arthropods; also, mainly in autumn and winter, seeds and nuts, especially hazel (*Corylus*) nuts and beech (*Fagus*) mast; sometimes feeds on flower buds and sap, and readily visits birdtables in winter. Little difference in foraging niche between sexes. Young fed largely with beetles and caterpillars, occasionally also seeds. In winter months spends up to 90 % of time in gathering food. Forages mainly on trunks and larger branches of trees, but also, especially in spring, on smaller branches and in twig clusters; can climb down tree trunks head first. Feeds also on the ground, especially in non-breeding season. Will remove pieces of bark to reach food items, but unable to chisel into wood in manner of a woodpecker (Picidae) unless wood is rotten. Adept at flycatching and diving after falling prey, and able to hover. Most pair-members remain together in close contact on territory throughout year, but may join mixed-species foraging flocks as these pass through. Stores food in all months, but especially in late summer and autumn; seeds stored singly, mostly in bark crevices but also in ground or in wall cavities; usually covers items with pieces of bark, lichen or moss. Cached food exploited mainly when temperatures low. In Siberia, specializes in seeds of Siberian stone pine (*Pinus sibirica*), and, following good cone crops, larders may contain enough food to last an entire year, potentially allowing territory-holder to survive a failed crop in following winter.

Breeding. Laying Apr–May, occasionally late Mar. very exceptionally Feb, timing varying with latitude and altitude; only exceptionally double-brooded. Monogamous and territorial; most remain throughout year in close contact with partner on territory. Nest a foundation of wood chips surmounted by bark flakes (usually of pine), rarely incorporating dry leaves, lichen, conifer needles and the like, placed in hole in tree, either natural hole or, more often, abandoned woodpecker hole in living trunk, usually 2–20 m above ground, occasionally existing hole in decayed wood enlarged by female; if entrance hole too large, size reduced by “plastering” with mud, and often interior of cavity also heavily plastered to protect against wind and rain, plaster occasionally incorporates animal dung (dung may be main building material in SW Iran), also rootlets and moss as binding material; sometimes nestbox used or, rarely, wall cavity, hole in rock face or building, crevice between tree roots, or even haystack or old nest of Eurasian Magpie (*Pica pica*) utilized; final choice of nest-site probably by female, and plastering of hole and nest-building also by female over period of 2–4 weeks, with only limited assistance from male; site often reused, sometimes for many years. Clutch 4–13 eggs, usually 5–9, white, lightly speckled and blotched red, reddish-brown or reddish-purple, markings usually concentrated at broader end, average dimensions 19.5 × 14.4 mm (race *caesia*); incubation by female, period 13–18 days; chicks brooded by female, fed by both parents, nestling period 19–29 days (mostly 20–26 days) in Europe, 18–22 days in Siberia; young largely independent after a further 8–14 days.

Movements. Generally sedentary, but juveniles may disperse, usually over short distances, in late summer and autumn. These movements sometimes become irruptions or "invasions" when populations high; in Europe numbers involved usually small (even in an irruption), and avoids even short water crossings, although vagrants recorded on Heligoland (N Germany) and on I of Man (Irish Sea); in cold years some may disperse into coastal areas of Spain. N & E populations undertake more frequent irruptions, during which considerable numbers move from breeding areas, probably owing to dependence on cones of Siberian stone pine; crop failure can result in mass emigration, e.g. in 1981 "several dozens of thousands" noted flying S from Mirmoye, in C Siberia, during 4th–12th Aug, and individuals of race *asiatica* may appear in N Finland and Sweden, where thousands sometimes recorded, and occasionally reach Norway and Estonia; such irruptions occur from Aug onwards, invaders leaving by Apr, although some remain to breed. Others disperse to N, exceptionally to tundra. In E Asia, race *uretica* may make rather limited movements S & E in winter, and *amurensis* is regular visitor to Korea, sometimes in large numbers; in 1980, some 30,000–40,000 recorded moving SW in groups of 40–50 birds along coast of Sea of Japan (in Ussuriland) on 3rd–6th Oct. Conversely, in NE China, only a single record from Beidaihe (Hebei), and a rare migrant at Shuangtaizhekou, at mouth of R Taizi (S Liaoning), although resident in nearby mountains. Throughout range, montane populations may undertake rather limited altitudinal movements.

Status and Conservation. Not globally threatened. Fairly common to locally common. Estimated European population c. 7,000,000 breeding pairs; in Siberia, numbers variable and closely tied to size of cone crop. Densities as high as c. 3–7 breeding pairs/ha in high-quality habitat, but generally lower, and usually much lower in coniferous forest and towards N of range; most sparsely distributed (sometimes rare) near tree-line, and also on S fringes of range. Parkland can support high densities owing to abundance of large trees, which may be scarce or absent in commercially managed woodland. Has spread N & W in W Europe (Norway, Netherlands), and expanded into Wales and N England; has become increasingly regular in Scotland, where breeding first proved in 1989. In Morocco has spread to Haut Atlas. Breeds irregularly in Finland (10–30 pairs) and N Sweden, following irruptions of race *asiatica* from E. Dependent on presence of large trees, and throughout range forest destruction and fragmentation lead to local decline and extinctions; is often rare or absent in small forest fragments.

2. Chestnut-vented Nuthatch

Sitta nagaensis

French: Sittelle des Naga **German:** Rostflankenkleiber **Spanish:** Trepador de las Naga
Other common names: Mountain/Naga Nuthatch

Taxonomy. *Sitta nagaensis* Godwin-Austen, 1874, Naga Hills, extreme north-east India.

Forms a superspecies with *S. europaea*, *S. cashmirensis*, *S. castanea*, *S. cinnamoventris* and *S. neglecta*. Formerly considered conspecific with *S. europaea*, but the two differ vocally, and in area of range overlap in E China (Fujian) they differ also in ecology (present species montane, *S. europaea* in lowlands); farther W in China, the two have been found at same locality in Sichuan and may overlap without intergradation, but situation far from clear, and more detailed study required. Birds of this species observed in NE Arunachal Pradesh (NE India) presumed to refer to race *montium*. Birds of this species observed in S Laos tentatively included in race *grisiventer*; allocation of widely separated populations (in W Myanmar, S Laos and S Vietnam) to same race, however, seems untenable, and more detailed study likely to demonstrate that one or more hitherto unnamed races are involved. Three subspecies currently recognized.

Subspecies and Distribution.

S. n. montium La Touche, 1899 – S & E China (SE Xizang, W & SW Sichuan, Yunnan and extreme SW Guizhou; isolated population in higher mountains of NW Fujian), extreme NE India (NE Arunachal Pradesh), E Myanmar (N Kachin S to S Shan State) and NW Thailand.

S. n. nagaensis Godwin-Austen, 1874 – NE India (Patkai Range of SE Arunachal Pradesh, Nagaland, Manipur, Cachar hills of S Assam, Khasi hills of Meghalaya) and W Myanmar (N Chin Hills)

S. n. grisiventris Kinnear, 1920 – SW Myanmar (Mt Victoria, and probably also other mountains of C & S Chin Hills), S Laos (Bolovens Plateau) and S Vietnam (Da Lat Plateau S to Mt Pantar).

Descriptive notes. 12.5–14 cm; 12–22 g (*montium*). A medium-small to medium-sized nuthatch, typical in shape and behaviour. Male nominate race has crown and upperparts blue-grey, with prominent black eyestripe from lores to side of mantle; lesser and median upperwing-coverts and tertials as back, remainder of wing dark grey, greater coverts broadly fringed and tipped dull blue-grey, primary coverts finely fringed blue-grey, smaller feathers of alula, secondaries and inner primaries fringed dull blue-grey; central tail feathers dull blue-grey with trace of dark shaft streak, other rectrices blackish-grey with dull blue-grey tips

(increasing in extent towards outermost rectrix); T3 with small white spot on tip of inner web, outer three feather pairs with larger white spot subterminally on inner web, outermost feather with pronounced white panel in centre of outer web; ear-coverts and side of neck, chin, throat and underparts very pale grey, faintly washed buff, rear flanks strongly contrasting brick-red; undertail-coverts grey with brick-red subterminally, broad white inverted triangle at tip and narrow rusty tip (appear rusty with tear-shaped white spots); axillaries buff, underwing-coverts blackish, long, under primary coverts and base of primaries white; in worn plumage, duller and slightly brown-tinted above, purer grey below; iris brown or dark brown; bill grey-black to blackish, base of lower mandible (and sometimes upper mandible) slate-grey or grey-blue; legs greenish-brown to reddish-brown, dark brown or black, claws horn-black. Distinguished from *S. himalayensis* mainly by lack of white in central tail feathers, and much paler underparts with contrasting reddish rear flanks. Female is as male but flanks rufous, concolorous with undertail-coverts. Juvenile resembles adult, but underparts on average slightly buffier. Races differ mainly in tone of underside: *montium* has chin and cheek buff-white, ear-coverts, side of neck and underparts dull pale buff with slight grey wash (greyer when plumage worn), white undertail-coverts very narrowly tipped and slightly more broadly fringed rufous (slightly more orange-rufous than flanks) and with concealed bases dull blue-grey (appear white with rufous "ladder" on each side and rufous centre); *grisiventris* resembles nominate but with underparts purer grey (pale to light grey), in fresh plumage (Oct) male shows no trace of buff (in worn plumage underparts slightly drabber grey, less whitish), female tends to have buff wash in centre of belly and vent. VOICE. Calls include slightly squeaky "sit", often as couplet ("sit-sit"), with varied emphasis and inflection and repeated at faster and slower speeds in irregular series; also a similar but lower and drier "chip" or "chit", often run into trilling "chit-it-it-it-it..." (not so emphatic and structured as the song); in alarm and agitation a nasal, inquisitive or whining "quirr", "kner" or "mew" and loud, hard, emphatic and metallic "tsit" notes, which may be doubled, or run into fast "tsit-tsit-tsit-tsit..." series (individual units sometimes repeated very rapidly, but rather higher, thinner and less full than song). Song a stereotyped fast, flat, monotonous stony rattle or trill, "chichichichichi..." or "tr-r-r-r-r-r-r-r-r-r...", c. 0.5-1 second per burst, and sometimes slightly rising in pitch towards end; individual notes often repeated so fast as to be almost indistinguishable, but sometimes rather slower, with shriller, better-spaced notes, "chi-chi-chi-chi-chi...", or much slower "diu-diu-diu-diu-diu" (latter may closely resemble one of the song variants of *S. europaea*).

Habitat. Hill evergreen forest, also pine (*Pinus*) forest (or stands of pines on drier ridges amid hill evergreen). In NE India recorded also in mixed and light deciduous forests, and in NE Myanmar in open oak (*Quercus*) and alder (*Alnus*) forest. In China, in holly oak (*Quercus illex*) and deciduous forest in SE Xizang (along R Tsangpo), in spruce (*Picea*), fir (*Abies*) and rhododendron (*Rhododendron*) in Yunnan, and in valley-bottom poplar (*Populus*) and walnut (*Juglans*) trees in Sichuan. Altitudinal range in NE India 1400–2600 m, occasionally to 3050 m; in Myanmar, recorded at 1220–2285 m in E but 1400–2810 m on Mt Victoria; found at 1300–2100 m in Thailand and at 915–2285 m in S Vietnam. In China, recorded at 1980–3650 m in SE Xizang, 1525–4570 m in Yunnan, 1200–3960 m in Sichuan and 1250–2480 m in Guizhou; isolated population occurs above 1000 m in NW Fujian.

Food and Feeding. No details of diet; presumably small arthropods and some seeds. Found singly and in pairs; outside breeding season also in small loose parties, often joining mixed-species foraging flocks. Often feeds on the ground, foraging over rocks and the sides of old cuttings, as well as on trees.

Breeding. Season Mar–Jun in NE India; in Myanmar, Apr to early Jun in E and recently fledged juveniles seen end Mar in W (Mi Victoria); Mar–May and nest-building in Jan in Thailand, and nest-building recorded in Jan in Vietnam; Apr–May in E China (Fujian). Nest a pad of scraps of bark or moss, lined with fur, placed up to c. 10 m above ground in hole in tree or stump, size of entrance sometimes reduced with “plaster”. Clutch 2–5 eggs, white, spotted with red over under-

ing reddish-violet spots, markings concentrated at larger end, mean dimensions 18.3 × 14 mm (race *montium*), 18.6 × 13.8 mm (nominata). No other information.

Movements. Resident. May be some withdrawal to lower elevations in winter, but also recorded at or near top of altitudinal range in cold months.

Status and Conservation. Not globally threatened. Fairly common throughout range; locally common.

Bibliography. Ali & Ripley (1983), Deignan (1945), Delacour & Greenway (1940), Delacour & Jabouille (1931), Dickinson (2006), Dickinson *et al.* (2006b), Duckworth *et al.* (1998), Harrap & Quinn (1996), Matthysen (1998), McCarthy (2006), Rasmussen & Anderton (2005b), Robson (2000b, 2002c), Robson *et al.* (1998), Stuart Baker (1932), Thet Zaw Naing (2003), Vaurie (1957b, 1959), Voisin *et al.* (2002), Voous & van Marle (1953).

3. Kashmir Nuthatch

Sitta cashmirensis

French: Sittelle du Cachemire **German:** Kaschmirkleiber **Spanish:** Trepador de Cachemira
Other common names: Brooks's Nuthatch

Taxonomy. *Sitta cashmirensis* W. E. Brooks, 1871, Kashmir.

Forms a superspecies with *S. europaea*, *S. nagaensis*, *S. castanea*, *S. cinnamoventris* and *S. neglecta*. Intermediate in many respects between *S. europaea* and *S. castanea*/*S. cinnamoventris* and has often been treated as conspecific with one or other of these, but differs in vocalizations and plumage (especially undertail-coverts); occurs within 5 km of *S. cinnamoventris* in N Pakistan (Murree Hills). One alarm call (like that of *Garrulus jay*) and nest construction suggest possible affinity with *S. neumayer* and *S. tephronota*. Monotypic.

Distribution. NE Afghanistan (Nuristan and Kohistan S to Safed Koh), N Pakistan (S to extreme N Baluchistan, and W Himalayas E from Chitral) and Kashmir; also NW Nepal (Humla, Mugu, Jumla and Dolpo E to Phoksumdo Tal, S to Surkhet).

Descriptive notes. 14 cm; 17.2–21 g. A medium-sized nuthatch, typical in shape and behaviour. Male has crown and upperparts, including upperwing-coverts and tertials, dull blue-grey, eyestripe from extreme base of bill and lores sooty black, extending to side of mantle, where it broadens somewhat; alula and primary coverts dark brownish-grey, latter fringed dull blue-grey, flight-feathers dark brownish-grey, secondaries and all except outer two primaries fringed blue-grey; central tail feathers dull blue-grey (sometimes dark shaft streak near tip), others blackish-grey with drab-grey at tip (more extensive on outer web), pale

tips progressively wider towards outermost rectrix, T4 with dull white spot on tip of inner web, T5 with dull white subterminal spot on inner web mid-way along feather; cheek and chin off-white, grading through pale buff on ear-coverts to buff or pale cinnamon on upper throat and side of neck, rich cinnamon on lower throat and breast, and cinnamon-rufous on side of breast, flanks and belly; rear flanks, vent and undertail-coverts deep rufous, undertail-coverts with at most a trace of greyish or greyish-brown on feather centres; thighs dull blue-grey with darker grey feather tips; axillaries blue-grey, finely tipped whitish, underwing-coverts blackish-grey, tips of under primary coverts and base of flight-feathers contrastingly white; in worn plumage upperparts slightly duller, but little seasonal variation in underpart coloration; iris reddish-brown to dark brown; bill blackish-grey or blackish-brown, basal half of lower mandible whitish to horn-grey; legs greyish, dark olive-brown or yellow-brown, soles dull yellow, claws dark slaty or blackish. Distinguished from *S. cinnamoventris* mainly by less dark underparts without contrasting white band from chin to ear-coverts, and uniform undertail-coverts. Female is as male, but chin and cheek with slight buff wash, lower throat and breast pinkish-buff, upper flanks, belly and vent cinnamon or rich cinnamon, rear flanks rich cinnamon. Juvenile resembles adult but may show more pale mottling on nape (paler feather centres) and dark barring in submoustachial area (dark grey feather bases). **VOICE.** Contact call a very high, thin, almost squeaking "tsi" or "tseet" in rather rapid (c. 3 notes per second), irregular extended series, "tsi, tsi, tsi-tsi, tsi, tsi...", each note rising slightly; excitement call, given in intraspecific conflicts and in alarm (often when human nearby), a repeated loud, far-carrying, harsh, rasping or groaning "kreeaa" or "schree-e" (0.4–0.8 seconds long), reminiscent of call of Eurasian Jay (*Garrulus glandarius*). Song a rapid, high-pitched, squeaking "pee-pee-pee-pee-pee".

Habitat. Coniferous, mixed and deciduous forests; apparently some dependence on presence of deciduous, broadleaf tree species, even in essentially coniferous habitats. Also in valley-bottom hazel (*Corylus*) scrub and poplar (*Populus*) groves in winter in Afghanistan. In Afghanistan recorded at 1850–2600 m, breeding proven 2000–2400 m; in Pakistan breeds at 2100–3050 m, locally up to 3350 m in Chitral, and in winter descends regularly to c. 1800 m, but recorded in Dec at 2500 m (in deep snow) in Murree Hills; breeds locally down to c. 1800 m in Kashmir; recorded at 2400–3505 m in Nepal.

Food and Feeding. Food insects, spiders (Araneae) and, especially in winter, seeds and nuts; grit often found in stomach. In summer found singly and in pairs; outside breeding season usually in mixed-species flocks. Forages on trunks and larger branches, usually at low levels, and often in understorey or on ground, on fallen and rotten trees and logs and moss-covered boulders. Utilizes both conifers and oaks (*Quercus*) if present. Recorded as hoarding seeds in captivity.

Breeding. Season May–Jun in Afghanistan, and late Apr to late Jun in Pakistan. Nest a layer of bark chips, seed husks and dried leaves, placed 2–9 m or more above ground (mostly over 10 m in Afghanistan) in tree hole, often abandoned woodpecker (Picidae) hole or natural knothole, in deep forest or in well-wooded open country; entrance may be reduced to c. 38 mm or less in diameter with "plaster" of wet mud (often small seeds mixed in), this sometimes forming cone-shaped short tunnel-like extension (reminiscent of nests of *S. neumayer* and *S. tephronota*), plaster occasionally extending for moderate distance around hole (perhaps consequence of reuse of nest from year to year and thus a build-up of material); male assists female in nest-building and plastering. Clutch 5–7 eggs, rarely 8, white with reddish spots and small blotches, mean size 19.7 × 14.4 mm; no information on incubation period; both sexes feed chicks, no information on duration of nestling period; fledged juveniles remain with adults for 5–6 weeks after leaving nest.

Movements. Resident, with some limited seasonal altitudinal movement.

Status and Conservation. Not globally threatened. Restricted-range species: present in Western Himalayas EBA. Common to locally common in E Afghanistan, Pakistan (although scarce in Murree Hills) and Kashmir; fairly common in Nepal.

4. Indian Nuthatch

Sitta castanea

French: Sittelle indienne

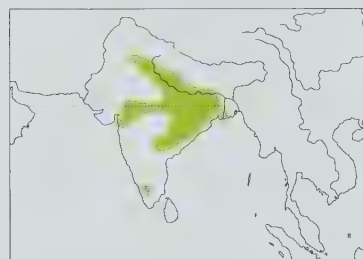

German: Kastanienkleiber

Spanish: Trepador Indio

Taxonomy. *Sitta castanea* Lesson, 1830, no locality = Bengal, India.

Forms a superspecies with *S. europaea*, *S. nagaensis*, *S. cashmirensis*, *S. cinnamoventris* and *S. neglecta*; formerly treated as conspecific with last two of these, but differs morphologically from both. Birds in S Bangladesh (Sundarbans) presumed to belong to this species, rather than to *S. cinnamoventris*. Birds from Anantagiri, in NE Andhra Pradesh (E India), described as race *prateri* on basis of slightly longer bill and paler underparts, but variation slight and naming of geographical races considered unwarranted. Monotypic.

Distribution. India on Gangetic Plain and terai from SC Punjab and E Rajasthan E to Bihar and West Bengal, and from N Maharashtra E to Orissa and S to N Andhra Pradesh, also in foothills of S Western Ghats from S Karnataka S through Nilgiris to Palghat hills (E Kerala and W Tamil Nadu); also SW Nepal and S Bangladesh (Sundarbans).

Descriptive notes. 12.5 cm; one male 12 g. A medium-small nuthatch with short, slender bill. Male has crown to nape and upper mantle light blue-grey, remainder of upperparts, including lesser and median upperwing-coverts and tertials medium blue-grey; extreme base of bill and lores blackish and extending into black eyestripe which expands broadly on side of mantle, sometimes with faint paler supercilium immediately behind eye; greater secondary coverts, primary coverts and alula dark grey, fringed and tipped blue-grey, flight-feathers dark grey-brown, secondaries and inner primaries broadly fringed blue-grey, primaries

P6–P3 fringed light blue-grey inward of emargination; central tail feathers blue-grey, others blackish-grey with broad dull blue-grey fringe on outer web and tip of inner web (widest on outermost rectrix), outer two feather pairs with off-white subterminal spot on inner web, T4 with small whitish tip on inner web; chin, cheek and fore ear-coverts white, feathers very faintly tipped darker, rear ear-coverts, side of neck and underparts brick-red, faintly washed orange; undertail-coverts blue-grey, broadly fringed brick-red, often with narrow pale creamy subterminal band (not visible in field), thigh feathers dark grey with blue-grey subterminal band and brick-red tip; axillaries blue-grey, tipped brick-red, underwing-coverts sooty black, longer under primary coverts and base of under primaries contrastingly white; in worn plumage, crown to upper mantle paler and more contrasting (some pale feather bases showing), remainder of upperparts dull blue-grey, flight-feathers duller and browner, underparts slightly paler and more orange; iris brown; bill black, variable blue-grey base of culmen, cutting edges and lower mandible; legs dark brown, soles pale yellow. Distinguished from very similar *S. cinnamoventris* mainly by having crown to upper mantle slightly paler than rest of upperparts, white more extensive on chin but more restricted on rear ear-coverts, slightly darker and browner (less orange) underparts, no white scallops on undertail-coverts, shorter and slimmer bill. Female is as male but paler, chin to cheek and fore ear-coverts off-white (less well defined), side of neck, throat and breast dull beige, belly and vent dull pinkish-cinnamon, rear flanks vinaceous cinnamon, undertail-coverts medium grey with pinkish-cinnamon fringes. Juvenile male resembles adult, but tiny pale feather centres on forehead and forecrown, feathers of crown and scapulars variably tipped faintly darker, greater upperwing-coverts finely tipped rufous, cheek and chin tipped faintly darker, throat slightly paler (some feathers with tiny pale centres), underparts slightly paler and more orange-brown; juvenile female underparts more uniform, slightly duller, drabber and more orange (less pinkish) than adult female, with less contrast between breast and belly. **VOICE.** Song a loud, mellow, rapid trill, level or slightly falling in pitch towards end, "chi-li-li-li-li-li-li", c. 12–13 notes per second, duration 1–2 seconds, very similar to slower song types of *S. cinnamoventris*; also slower, shorter and more musical variants at c. 8 notes per second, duration 1 second. Calls include short, stony "stii", sometimes accelerating into very fast trill (c. 18 notes per second).

Habitat. Deciduous forest, village groves, roadside trees, sometimes gardens; in N India and SW Nepal confined to lowlands, but elsewhere in India occurs both in plains and in hills to c. 1000 m.

Food and Feeding. Food insects and spiders (Araneae), also seeds and nuts. Found singly, but more often in pairs or loose family parties; frequently joins mixed-species foraging flocks. Usually forages in upper part of tall trees.

Breeding. Season late Feb to May (most eggs laid in Mar) in N of range and Apr–Sept in S (Andhra Pradesh). Nest a meagre layer of dried leaves, wood chips, bark fragments or moss, usually placed in natural cavity up to 9 m above ground in tree, especially mango (*Mangifera*), entrance usually reduced with a "plaster" up to 50 mm thick of mud, saliva and tree resin (even when hole selected is small enough, area around, both outside and inside, may be plastered), any damage to masonry quickly repaired; hole may be reused in successive years. Clutch 4–5 eggs, rarely 6, white to pale pink, finely spotted reddish, spots may be concentrated at larger end, average 17 × 16.5 mm; incubation by female, fed on nest by male, period 11–12 days; no information on nestling period.

Movements. Resident; no evidence of altitudinal movements.

Status and Conservation. Not assessed. Probably not globally threatened. Common but rather local; commonest in N, especially in Bihar, and scarce in Madhya Pradesh and Andhra Pradesh. Records of a "chestnut-bellied nuthatch" from Sundarbans of S Bangladesh presumed to refer to present species. Occurs in several protected areas, including Mudumalai National Park, in W Tamil Nadu (on borders with Karnataka and Kerala), in SW India.

Bibliography. Ali & Ripley (1983), Deignan (1945), Dickinson (2006), Dickinson *et al.* (2006b), Gill (1923), Harrap & Quinn (1996), Law (1948), Matthysen (1998), McCarthy (2006), Rasmussen & Anderton (2005b), Ripley (1959c), Stuart Baker (1922, 1932), Vaurie (1950b), Voous & van Marle (1953).

5. Chestnut-bellied Nuthatch

Sitta cinnamoventris

French: Sittelle de Blyth

German: Zimbauchkleiber

Spanish: Trepador Ventricastano

Other common names: Cinnamon-bellied Nuthatch

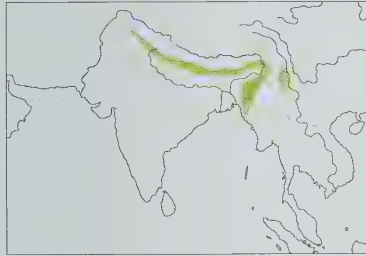

Taxonomy. *Sitta cinnamoventris* Blyth, 1842, Darjeeling, north India.

Forms a superspecies with *S. europaea*, *S. nagaensis*, *S. cashmirensis*, *S. castanea* and *S. neglecta*; often treated as conspecific with last two of these, but differs morphologically from both. Overlaps in range with *S. nagaensis* in parts of NE India and SE Asia, but the two replace each other

Affinities within genus uncertain. Formerly considered conspecific with *S. victoricae* on grounds of common character of white in central tail feathers, but otherwise morphologically distinct and both occur on Mt Victoria (Myanmar), although probably separated altitudinally; suggested also as being close to *S. pygmaea* and *S. pusilla*, and relationship with these two supported by possibility that

partners may duet; alternatively, strongly developed black eyestripe and uniform undertail-coverts may indicate affinity with *S. yunnanensis*. Birds from Lushai Hills (Mizoram), in NE India, described as race *lushaiensis* on basis of somewhat paler underside, but variation slight and naming of geographical races considered unwarranted. Monotypic.

Distribution. NW Himachal Pradesh (Chamba) E in Himalayas to NE India (NE Arunachal Pradesh, also from Nagaland S in hills to S Mizoram) and W & NE Myanmar, also adjacent parts of S China (S Xizang, W Yunnan); also NW Vietnam (Fan Si Pan, in NW Tonkin). Single records from E Myanmar (near Kengtung, in S Shan State) and N Laos (Tranninh plateau) possibly refer to non-breeding visitors.

Descriptive notes. 12 cm; 11–17 g. A small, dumpy, relatively short-billed nuthatch. Male in fresh plumage (Sept–Apr) has crown to rump dull blue-grey, sometimes crown and especially nape and upper mantle slightly paler; forehead, lores and eyestripe sooty black, expanding broadly on to side of upper mantle, sometimes an indistinct narrow grey-white supercilium just above and behind eye; upperwing dark grey-brown, wing-coverts (including primary coverts) fringed blue-grey, extensively so on outer web of greater coverts, alula fringed blue-grey on outer web, tertials medium grey (tinged blue on outer

web), secondaries broadly fringed blue-grey, primaries finely fringed light grey, pale fringes progressively restricted to base of feather towards outer wing; central tail feathers dull blue-grey, slightly darker and greyer along shaft and at tip, basal half of outer web adjacent to shaft white, basal two-thirds of inner web white, other rectrices sooty black, outermost with white diagonal stripe subterminally across feather, next to outermost with large white subterminal spot on inner web; chin, cheek and throat whitish, variably washed buff, grading into cinnamon-orange on upper and rear ear-coverts, upper flanks and breast, and darker and richer orange-cinnamon on belly and flanks to undertail-coverts; axillaries grey-buff, underwing-coverts sooty black, base of under primaries and secondaries (inner webs only) white; in worn plumage, whitish feather bases may show on nape and upper mantle, black eyestripe more extensive, especially at rear (on upper mantle), wings darker and sootier (blue-grey fringes abraded), underparts paler and whiter, may be buff-white on breast and belly; iris brown; bill black or blackish-brown, base of lower mandible bluish-white or grey; legs dark brown, dark greenish-brown or dark yellowish-brown, soles greyish-white. Distinguished from *S. vittoriae*, which likewise has white in central tail feathers, by less boldly patterned head and less contrastingly patterned underparts; from similar *S. cashmirensis* (which also has uniform undertail-coverts) mainly by white in central rectrices (when visible), smaller size and shorter bill, also by slightly paler underside with less well-defined white throat, cheek and ear-coverts. Female is as male, but ear-coverts and underparts on average slightly paler and duller. Juvenile resembles adult. VOICE. Calls include squeaky single “nit” and soft, mellow “chak” or “tschak”, given singly at irregular intervals; harder and sharper, almost stone-clicking versions may be given in couplet (“chak’kak”) or in short, irregular groups, and may be combined into monotonous rattle in which up to 25 notes at rate of c. 10 per second, “chik’kak’ka’ka’ka’ka’ka...”; in alarm or agitation a similar but louder, shrill (sometimes squeaky) but full “chik”, near-disyllabic “ts’lik” or even shriller “tsik”, often in series which initially quite fast but slow to c. 3 notes per second, and in prolonged series can tail off to maximum of c. 2 notes per second, notes sometimes then becoming shriller “shree” which may be repeated for minutes at a time (these series from agitated bird may be at higher and lower pitches, perhaps reflecting difference between sexes). Duetting by presumed partners, with higher and thinner “tsik” calls and lower but squeaky “chik” notes, in a chatter almost like that of sparrow (*Passer*). Also gives high-pitched, thin, sibilant “sisirrr” or “sisisit”, variety of fussy twitterings, and strange long, shrill squealing or quavering notes, e.g. “kreeeeeeeeee” or “preeeehh”; these may rise or fall in pitch, and last almost 1.5 seconds. Song a rapid repetition of a single note in a trill lasting c. 0.8–1.8 seconds, some fast (up to c. 15 notes per second), some slow (c. 5 per second), varying both among males and within individual male’s repertoire, e.g. slightly querulous or inquisitive series of piercing “pee” notes and slower and much mellower but still loud, whistled “dui-dui-dui...”.

Habitat. Temperate broadleaf and mixed forests. In Himalayas and NE Myanmar middle-altitude oak (*Quercus*) and rhododendron (*Rhododendron*) forests, with preference for mossy forest, also at higher altitudes in mixed forests of fir (*Abies*), hemlock (*Tsuga*), rhododendron, oak and maple (*Acer*), although apparently avoids pure stands of conifers; thus, found in oak–rhododendron forest at 1525–2135 m and maple–hemlock forest at 2745–3050 m in Nepal. In NE hill states of India found in broadleaf evergreen forest. Breeds in Himalayas at 1500–3500 m, highest in E, with optimum zone c. 1800–2800 m; in non-breeding season recorded down to 915 m in Nepal, 945 m in Sikkim and 500 m in Bhutan, but also as high as 3050 m in Jan in Nepal and N India (Darjeeling). In NE hills of India found above 1700 m, and in adjacent W Myanmar (Chin Hills) at 1675–2500 m; in NE Myanmar at 1525–2900 m (but down to 980 m in winter) and recorded once at 2285 m in S Shan State; in S China (W Yunnan) noted at 2000–2745 m; in NW Vietnam from 2000 m to at least 2800 m, and in N Laos at c. 2000 m.

Food and Feeding. Food insects, also nuts and seeds. Found singly and in pairs, in summer and early autumn also in flocks of up to ten individuals (comprising family parties); often joins mixed-species flocks in non-breeding season. Forages on mossy branches, usually in upper parts of trees, less frequently on trunk; occasionally in low shrubs.

Breeding. Season mid-Mar to early May in Indian Subcontinent, and probably similar in NE Myanmar. Nest built by female, male occasionally providing material, a pad of green (sometimes dried) moss, mossy fibres and rhododendron leaves, placed 1–15 m above ground in tree cavity, usually in oak; hole if too large may be “plastered” up with mixture of mud and berries, diameter reduced to 25–38 mm, plaster setting rock hard. Clutch 4–7 eggs, white, densely covered with dark red spots and blotches, which may form ill-defined ring at larger end, mean size 18.6 × 13.4 mm; incubation of eggs and feeding of chicks reported as by both sexes; no information on duration of incubation and nestling periods.

Movements. Resident, with seasonal altitudinal movements.

Status and Conservation. Not globally threatened. Common in Himalayas, perhaps occurring at highest densities in E; variously rare, uncommon and fairly common in NE hill states of India, where probably occurs at reduced densities. More or less uncommon in NE Myanmar, and perhaps rare in adjacent W Yunnan (S China). Common in NW Vietnam. Status in Laos unknown, and only one record (of a single flock at Tranninh), also only one record from E Myanmar; both of these possibly refer to non-breeding visitors from N parts of range.

Bibliography. Ali & Ripley (1983), Dickinson *et al.* (2006b), Harrap & Quinn (1996), Hume & Oates (1889), King *et al.* (2001), Martens & Eck (1995), Matthysen (1998), Rasmussen & Anderton (2005b), Robson (2000b), Spierenburg (2005), Stuart Baker (1922, 1932), Sultan & Khan (2000), Thet Zaw Naing (2003), Vaurie (1957b).

8. White-browed Nuthatch

Sitta vittoriae

French: Sittelle du Victoria **German:** Weißbrauenkleiber **Spanish:** Trepador Birmano
Other common names: Victoria Nuthatch

Taxonomy. *Sitta vittoriae* Rippon, 1904, Mount Victoria, Chin Hills, Myanmar.

Formerly considered conspecific with *S. himalayensis*, both having white in central tail, but otherwise morphologically distinct and both occur on Mt Victoria, although probably separated altitudinally. Small size and prominent white supercilium suggest possible affinity with *S. yunnanensis*. Monotypic.

Distribution. Mt Victoria and nearby Mindat (S Chin Hills) in W Myanmar.

Descriptive notes. 11.5 cm. A small nuthatch with tiny, spike-like bill. Has forehead and narrow supercilium (to rear of ear-coverts) whitish, crown to rump dull blue-grey, nape and upper mantle paler and with white feather bases showing (variable whitish mottling); narrow black eyestripe, broadening considerably on upper mantle; upperwing dark grey-brown, wing-coverts (including primary coverts) fringed blue-grey, outer webs of tertials extensively blue-grey, secondaries fringed blue-grey, primaries finely fringed paler at base; central tail feathers with basal half of inner web and narrow streak along shaft on outer web whitish, grading on distal half to blue-grey with dark border of outer web and marbled with grey towards tip, often with triangular black spot near tip of shaft, remaining rectrices blackish-grey, small white triangle of white on tip of inner web of T4, large white subterminal spot on inner web and variable white subterminal streak along shaft on outer web of T5, and large white subterminal streak diagonally across both webs of T6; lores and cheek whitish, upper and rear ear-coverts orange-rufous (rearmost ear-coverts often contrastingly white), rufous then forming continuous line down side of neck and onto flanks, rear flanks darker and more extensively rufous, innermost rear flanks blue-grey; chin, throat, lower ear-coverts, breast and belly white, vent and undertail-coverts cinnamon-rufous, thighs grey; axillaries blue-grey, under primary coverts sooty black, longest coverts and base of primaries contrastingly white; iris red-brown or dark brown; bill slate-grey, paler on culmen and lower mandible, black at tip; legs dull yellowish-brown or olive-brown. Easily distinguished from *S. himalayensis*, which similarly has white in central tail feathers, by head pattern (white forehead and broad supercilium, more sharply defined black eyestripe) and more contrastingly patterned underparts. Sexes apparently similar. Juvenile is reported as being much paler than adult on side of neck (possibly also on breast and flanks). VOICE. Calls include “pee”, variably insistent and tooting or less emphatic (and then recalling a lost domestic chick), repeated steadily at 2–3 notes per second for long periods, sometimes declining in speed and volume towards end of phrase, also a subdued, liquid “pit” and more sibilant “tsit”. Song a slow, mellow trill made up of “tuwi” couplets at rate of 4 couplets per second, whole phrase lasting c. 1.5 seconds and rising in pitch, “tuwi-tuwi-tuwi-tuwi-tuwi-tuwi”.

Habitat. Oak–rhododendron (*Quercus*–*Rhododendron*) forest. On Mt Victoria from 2285 m to summit at 3053 m; in recent study recorded only above 2450 m (habitat below 2450 m may now be unsuitable), with nests found at 2510 m and 2750 m; species found only above 2600 m during expedition in late 1930s (earlier records at lower altitudes were made during breeding season and thus did not represent winter dispersal). Recorded at 2440–2560 m at Mindat. Occurs at higher elevations than *S. himalayensis* where ranges overlap.

Food and Feeding. Food small insects. Usually found singly or in pairs, only occasionally in small flocks of up to four individuals. Tends to forage on outer branches (69.6% of observations), less often inner branches (19.6%) or trunk (10.8%), mostly on oaks and rhododendrons. Items gleaned from mosses, lichens and other epiphytes, or from beneath dislodged bark fragments.

Breeding. Nest-building observed on 12th Mar, and nests with chicks recorded in early Apr. Three nests known, the first built by female over period of c. 6 days, all sited in cavity, respectively 4 m, 6 m and 10 m above ground, no mud “plaster” around nest-hole entrance. Only female observed to feed young. No other information.

Movements. Resident.

Status and Conservation. ENDANGERED. Restricted-range species: present in Eastern Himalayas EBA. Global population estimated at 2500–9999 individuals, all within area of 820 km²; thought to be decreasing. Recent observers report this species variously as fairly common and as sparsely distributed, and it may be local even within its highly restricted range. Mt Victoria lies within Natna Taung National Park, but this appears to offer little protection; forest has been cleared below 2000 m and is degraded between 2000 m and 2500 m.

Bibliography. Anon. (2007i), Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (2006b), Harrap & Quinn (1996), Rasmussen & Anderton (2005b), Robson (2000b), Robson *et al.* (1998), Stattersfield & Capper (2000), Stressemann & Heinrich (1940a), Thet Zaw Naing (2003), Vaurie (1957b).

9. Pygmy Nuthatch

Sitta pygmaea

French: Sittelle pygmée **German:** Zwergkleiber **Spanish:** Trepador Enano
Other common names: Californian Nuthatch

Taxonomy. *Sitta pygmaea* Vigors, 1839, Monterey, California, USA.

Forms a superspecies with *S. pusilla*; sometimes considered conspecific, but differs in e.g. plumage, vocalizations, and various aspects of biology. Together, the two are sometimes considered closely related to *S. himalayensis*, shared characters including white at base of tail and nape feathers. Alternatively, superspecies may represent an older invasion of North America by ancestral stock of *S. canadensis*, and in recent limited phylogenetic analysis of mitochondrial DNA present species emerged basally to a clade containing the “*S. canadensis* group”. Geographical variation slight; in particular, all Mexican races apparently very similar (*chihuahuae* often merged with *melanotis*) and taxonomic revision possibly needed. In California (SW USA), *melanotis* intergrades with nominate (on Howell Mt, in Napa County) and with *leuconucha* (in region of San Bernardino Mts). Proposed race *canescens*, described from Lee Canyon, in Charleston Mts (Nevada), in SW USA, considered indistinguishable from *melanotis*. Seven subspecies recognized.

Subspecies and Distribution.

S. p. melanotis van Rossem, 1929 – extreme SW Canada (S British Columbia), and mountains of W USA (Cascades, Sierra Nevada, Rocky Mts and desert ranges of Great Basin) S to California (Riv-

erside County) and E to W Montana, SW South Dakota (Black Hills), W Nebraska (Pine Ridge area), NW Colorado (Douglas Mts), New Mexico and W Texas (Davis Mts, Guadalupe Mts), also extreme N Mexico in NE Sonora (San José Mts) and NW Coahuila (Sierra del Carmen).

S. p. pygmaea Vigors, 1839 – C coastal California (from Mendocino County S to San Luis Obispo County).

S. p. leucomucha Anthony, 1889 – mountains of extreme S California (S of San Bernardino Mts) and extreme NW Mexico (Sierra de Juárez and Sierra San Pedro Mártir, in N Baja California).

S. p. chihuahuae van Rossem, 1929 – NW Mexico at scattered sites in Sierra Madre Occidental from S Sonora and W Chihuahua S to Nayarit, SW Durango, NW Zacatecas and N Jalisco (S to Santa Teresa and Guadalupe).

S. p. eli A. R. Phillips, 1986 – N & NC Mexico in Sierra Madre Oriental, SE Coahuila (SE of Saltillo) and SW Nuevo León (Cerro Potosí).

S. p. brunescens Norris, 1958 – SW Mexico in S & W Jalisco (Sierra Nevada de Colima), Colima and SW Michoacán; possibly also NE Nayarit.

S. p. flavinucha van Rossem, 1939 – E & C Mexico in W Veracruz (Las Vigas, Pico Orizaba), Distrito Federal, Morelos and W Puebla (Cerro San Miguel, Volcán Ajusco, La Cima, Popocatepetl).

Descriptive notes. 11 cm; average 9.3–11.4 g. A very small nuthatch with brownish cap.

Nominate race has crown to upper mantle brownish-olive, paler spot in centre of upper mantle (concealed or indistinct), remainder of upperparts, including tertials and upperwing-coverts, medium blue-grey; inner webs of tertials slightly darker, concealed inner webs of greater coverts dark brown; lores and ill-defined eyestripe sooty brown, contrasting little, if at all, with cap; alula and primary coverts blackish, smaller feathers of alula fringed blue-grey, primary coverts finely fringed medium grey, flight-feathers sooty brown, secondaries fringed grey, inner primaries finely fringed light grey, P3 broadly fringed white on basal third, P4–P7 with whitish fringe around emargination, P3–P6 with white at base (showing as slight flash at tips of primary coverts); central tail feathers blue-grey, broad off-white shaft streak on basal half, other rectrices blackish-grey, tipped brownish-olive (broadly so on outermost feather), outer two feather pairs with broad off-white diagonal subterminal stripe; chin, cheek and ear-coverts off-white, darkening to pale buff on side of neck, throat and upper breast and yellow-buff on rest of underparts, flanks pale grey; axillaries light grey, underwing-coverts dark grey, longer under primary coverts and base of primaries white; in worn plumage, cap slightly paler, lores and eyestripe slightly more contrasting, pale feather bases on upper mantle more obvious, upperparts slightly duller and less blue, underparts paler and less buff; iris brown; upper mandible blackish, lower mandible dusky grey with pale blue-grey base; legs grey, soles often pale yellow or greenish-yellow. Differs from very similar *S. pusilla* mainly in darker crown, somewhat darker eyestripe, and more white on fringes of primaries. Sexes similar. Juvenile resembles adult but greyer above, with little contrast between crown and upperparts (often some pale buff-white of feather bases visible in centre of upper mantle), lores and eyestripe dark sooty grey, greater upperwing-coverts fringed brownish, underparts pale greyish-white with buff wash (similar to worn adult), flanks pale buff-brown; base of lower mandible pink to off-white for up to three months after fledging. Races differ little: *melanotis* is like nominate, but crown to mantle with greyish cast, eyestripe better defined (especially behind eye), colour of underparts varies from very pale buff (in interior USA) to rich buff, also relatively longer wing and shorter tarsus; *leucomucha* resembles previous (cap colour similar), but upperparts paler and greyer, underparts whiter, darker and longer-billed than other Mexican races; *chihuahuae* is as nominate, but upperparts on average slightly darker, wing longer, bill and tarsus relatively shorter; *brunescens* is similar to previous, but cap on average slightly browner (olive-brown), nuchal spot slightly more prominent and tinged yellow-buff, underparts buffy (as *melanotis*); *flavinucha* also is similar, but cap may be fractionally less brown (although birds from Mt Toluca, in Mexico, may match preceding race), mantle spot only faintly tinged buffy yellow; *eli* also is like *chihuahuae*, but longer wing, tail and tarsus (probably largest race), and has upperparts paler, underparts dull and pale, but bill smaller, juvenile lacks yellow-brown fringes on median and greater wing-coverts and is whiter (less buffy) below. Voice. Noisy. Call a clear, high-pitched, rapid “kit-kit, kit-kit...”, “pit-pit, pit, pit-pit...” or “peep peep”, in variety of pitches and sequences, in flocks may be prolonged into twittering “de-de-de-de-de-de...pit-pit-dit, pi-dit, pi-dit...” (sometimes calls of different individuals become so mixed as to sound like a brood of chicks); other calls include high-pitched “bree-ee-ee-ee-ee-ee” (when tending young, especially by female). Song a rapid, high-pitched, staccato sequence of disyllabic piping notes, “wee-bee, wee-bee, wee-bee...” or “ki-dee, ki-dee, ki-dee”; song given Feb to mid-summer in California, but similar calls heard throughout year; alarm also similar although tends to be a faster repetition of more monosyllabic or irregularly disyllabic notes (sometimes just 3–4 notes). Pair-members have rapid, synchronized duets, e.g. male/female as “poo toot/pee tit/poo toot/pee tit”. Juvenile’s call a rapid, slurred, chattering “durr-urp-urp-urp-urp...” varied with louder “swe-swe swe-swe swe-swe swe-swe”, differs from that of *S. pusilla*.

Habitat. Almost exclusively in forests of long-needled pines, distribution closely paralleling that of ponderosa pine (*Pinus ponderosa*) and Jeffrey pine (*Pinus jeffreyi*), and in California also in Monterey pine (*Pinus radiata*) and bishop pine (*Pinus muricata*); occasionally other conifer species, e.g. lodgepole pine (*Pinus contorta*) in N Colorado. Prefers open, park-like woodland, and in Mexico very much a bird of high, cold pine forests; favours old-growth, mature, undisturbed forest, and populations in unlogged forest significantly higher than in logged forest. In winter, may occur in Douglas fir (*Pseudotsuga menziesii*) and pinyon-juniper (*Pinus-Juniperus*) woodlands, mixed pine-oak (*Pinus-Quercus*) forest, riparian woodland and conifer plantations, but very rarely in pure deciduous forest. From near sea-level to 1220 m in coastal California, otherwise 550–3350 m in USA; 1585–2745 m in Baja California and 1830–4270 m in remainder of Mexico (reaching highest altitudes in S).

Food and Feeding. Food in summer mainly insects and spiders (Araneae), in autumn and winter shifting to variable extent to pine seeds; young fed principally with animal food, but well-developed nestlings sometimes given pine seeds (after hard shell removed). Will visit feeders to eat suet and sunflower (*Helianthus*) seeds. May store pine seeds, hiding them in bark crevices. Family-members tend to stay together in autumn, subsequently joining with other families to form stable winter group, which may roam over area formerly occupied by several territories, occasionally more widely. In some areas tends to form single-species group (usually of 5–16 individuals, but up to 100 recorded), but in montane habitats joins mixed-species foraging flocks. Forages almost exclusively in pines, climbing up and down trunk, over and under branches, and exploring twigs, needle clusters and cones; searches open cones for insects. Flakes off pieces of bark to find insects, and occasionally fliccatches or picks off insects while hovering. Wedges pine seeds in bark crevices and hammers vigorously at them. Single record of tool use: an individual, while holding a 3-cm

twig, worked along a branch, probing the bark, and when it found something it dropped twig and pecked at the object. Occasionally utilizes broadleaf trees and shrubs, and sometimes descends to ground to take swarming termites (Isoptera), to extract seeds from fallen cones and to retrieve fallen items; has been noted as consuming a flaky layer of ice (in a very dry winter).

Breeding. Season Apr to early Aug in USA, possibly slightly earlier in S Mexico; very occasionally double-brooded (probably all dates after Jun refer to second broods). Tends to form permanent pair-bond. Up to 40% of pairs assisted by 1–3 (exceptionally four) male helpers, usually immature or sibling related to the pair (and always from same winter group), which assist in defending nest and territory, nest-building and nest sanitation, feed female on nest, feed young, and at all stages of breeding cycle roost in nest; most help for one year, but a few assist same pair for two or more years, some participate throughout breeding cycle, others arrive mid-cycle after own nest failure. Lives all year in territory, selected by male and comprising nesting/roosting site and foraging areas, territories of pairs with helpers on average larger; little overlap between territories, but actively defended only in breeding season (defence usually limited to vicinity of nest-site). Nest, built by both sexes, a cup made from bark shreds, fine moss, grass, plant down, fur, hair, cocoons, and other soft fibrous material, usually with feathers incorporated, placed in cavity 0.3–2.3 m (usually 5–15 m) above ground in standing dead tree or dead snag on live tree, mostly conifer, with hair, feathers and similar material used to “caulk” cracks in walls; usually excavates own hole (or reuses old cavity), but may utilize old hole of woodpecker (Picidae), and recorded as nesting in fence post, telephone pole and old building; excavation, which takes 3–6 weeks, undertaken by both sexes (and helpers, if present), and often several holes started before final selection made; nestbox also used, especially in absence of suitable natural sites. Clutch 2–12 eggs, usually 5–9 (average 7), white, sparsely and unevenly spotted reddish-brown, markings often concentrated at larger end, mean size 15.8 × 12.2 mm (nominate); replacement clutches unusual; incubation by female, fed on and off nest by male and by any helpers present, period 12–17 days; chicks usually fed by both sexes, male making more feeding visits, fed also by helpers, but brooded only by female, nestling period 14–22 days; juveniles not independent until a further 23–28 days and may continue to be fed until c. 50 days after fledging. Pairs with helpers less likely to lose nest to predation or other causes of nest failure, and helpers may benefit by gaining entrance to winter group, membership of which is critical for survival.

Movements. Mainly resident; limited seasonal altitudinal movements by montane populations irregularly Jul–Dec, both to higher elevations (up to timber-line) and to lower valleys and cities along edge of mountains. Otherwise, little autumn and winter dispersal with remarkably few records from plains, even from areas immediately adjacent to breeding range. Irregular “micro-irruptions”, when dispersal slightly more pronounced, perhaps associated with failure of cone crop, thus a rare visitor to Oklahoma panhandle and rare migrant and winter visitor in Texas away from breeding areas; rare and erratic visitor to coastal lowlands of SW California, to SW Arizona (adjacent to breeding areas) and to E New Mexico. Away from these areas, extremely rare vagrant to SW British Columbia (near Vancouver and on Vancouver I), C & E Montana, North Dakota, E Nebraska, Kansas (flock of about ten individuals at Wichita, Nov 1961–Jan 1962, also spring and autumn records in six counties), and Iowa.

Status and Conservation. Not globally threatened. Common in much of range, and locally abundant. In N of range, uncommon in Canada (British Columbia) and in US states of Washington, Montana and Wyoming, and rare in Nebraska and South Dakota. Elsewhere in USA, common in Oregon, California, Arizona and New Mexico, and often abundant and one of most numerous bird species in pine forests, although numbers fluctuate markedly (probably in association with size of cone crop); fairly common within breeding range in Idaho, Nevada, Utah, Colorado and Texas. Recorded densities vary widely, from 0.75 to 12.25 pairs/10 ha. In Mexico, common in N Baja California and locally fairly common in other parts of range. In non-breeding season, high densities found in Spring Mts (S Nevada), foothills around Spokane (Washington), foothills of Rocky Mts in Colorado, and Monterey (California). Human population growth and the resulting logging, fire suppression, grazing, development and road-building have reduced the amount of available habitat, and forestry practices (especially the removal of suitable nesting trees) have degraded much remaining habitat.

Bibliography. Bent (1948), Bleitz (1951), Boek (1969), Burleigh (1972), DeSante & Pyle (1986), Güntert *et al.* (1988), Harapp & Quinn (1996), Kingery & Ghalambor (2001), Marshall (1957), Matthysen (1998), Norris (1958), Phillips (1986), Spellman & Klieka (2006), Sydesman (1989), Sydesman *et al.* (1988).

10. Brown-headed Nuthatch

Sitta pusilla

French: Sittelle à tête brune

German: Braunkopfkleiber

Spanish: Trepador Cabecipardo

Taxonomy. *Sitta pusilla* Latham, 1790, Carolina, Jamaica = South Carolina, USA.

Forms a superspecies with *S. pygmaea*; sometimes considered conspecific, but differs in e.g. plumage, vocalizations, and various aspects of biology. Together, the two are sometimes considered closely related to *S. himalayensis*, shared characters including white at base of tail and nape feathers. Alternatively, superspecies may represent an older invasion of North America by ancestral stock of *S. canadensis*. Geographical variation slight, size decreasing clinally from N to S, with a “step” between more or less isolated population in Maryland (large, long-winged, deep-billed) and that of Virginia/North Carolina; distinctiveness of race *insularis* requires confirmation. Two subspecies provisionally recognized.

Subspecies and Distribution.

S. p. pusilla Latham, 1790 – USA from extreme SE Oklahoma, E Texas and W & S Arkansas (S from Ouachita Mts) E to SE Tennessee, C & E North Carolina, SE Virginia, tidewater areas of SE Maryland (S from Talbot County, mostly E of Chesapeake Bay) and extreme S Delaware, S to Gulf States (absent from grassland strip along coast) and Florida (S to Collier County).

S. p. insularis Bond, 1931 – Bahamas (Grand Bahama).

Descriptive notes. 10.5 cm; average 10.2 g. A very small nuthatch with brown cap. Nominate race in fresh plumage (Aug–Oct) has lores, crown, nape and upper mantle warm pale brown, variable whitish spot in centre of uppermost mantle, upperparts medium blue-grey, inconspicuous dark narrow eyestripe (in worn plumage, lores and ear-coverts contrastingly darker, forming a mask); lesser and median upperwing-coverts grey, fringed blue-grey, greater coverts and tertials grey, faintly washed brown, greater finely fringed light grey or blue-grey, tertials slightly darker on inner web, alula, primary coverts and flight-feathers dark

brownish-grey, primary coverts finely fringed mid-grey, secondaries fringed light grey, inner primaries very finely fringed pale grey, P3–P5 narrowly fringed off-white around emargination; central tail feathers blue-grey, slightly paler at base (and may show whitish along shaft), other rectrices sooty black with medium to light grey tip (narrow on T2–T3, broad on T6), outer two feather pairs with greyish-white broken diagonal subterminal bar; cheek, ear-coverts and side of neck whitish, chin white, washed buff and darkening to pale buff on throat, buffish or pale cinnamon-buff on breast (quickly wears to pale buff) and greyish-buff on belly to undertail-coverts and thighs, with side of breast and flanks light grey; axillaries light grey, underwing-coverts medium grey, longer under primary coverts and base of primaries white; in worn plumage, cap rather paler, feather tips extensively bleached to pale greyish-drab or whitish-buff, lores and eyestripe contrastingly darker brown, nuchal spot whiter and more prominent, upperparts slightly duller and less blue, underparts paler, whitish to dirty pale grey with buff tinge; iris dark brown; bill dark slate, base of lower mandible extensively pale bluish-grey; legs dark grey, soles paler. Distinguished from very similar *S. pygmaea* mainly by somewhat paler crown (much paler in worn plumage) and less prominent dark eyestripe, more conspicuous white nuchal spot, less white on primary fringes, less white in tail. Sexes similar. Juvenile is marginally distinct from adult, has cap generally greyer and mantle slightly browner (thus much less contrast between cap and mantle), nuchal spot less conspicuous, greater upwing-coverts fringed buffish, tertial and secondary fringes washed cinnamon, underparts as fresh-plumaged adult but with slight rosy flush, browner flanks. Race *insularis* is similar to nominate but has longer, thinner bill and darker eyestripe. VOICE. Rather vocal. Contact call a soft “tip” or “pit”, during foraging often given continuously for extended periods at up to 60–90 notes per minute in twittering “pit, pit, pit...” sequence; other calls include so-called “rubber ducky” call as alarm, in excitement or by individual separated from flock, an explosive squeaky, nasal “ziu!” or “niu!”, or more usually a “ziu-uu” couplet (when very like a toy rubber duck being squeezed and released), second note repeated up to twelve times but most commonly 1–3 times, “ziu-uu-uu-uu”, and calling occasionally continued at up to 80 notes per minute for several minutes. Loud repeated series of 2-note “rubber ducky” calls given by male in spring as “song”. Juvenile emits buzzy “sh-h-r-r-p, sh-h-r-r-p” (given also by adult). Voice generally slightly lower-pitched, less pure and more reedy than that of *S. pygmaea*, and song generally slower.

Habitat. Found almost exclusively in association with pines, especially loblolly pine (*Pinus taeda*). Favours mature old-growth pine forest in which natural fire patterns have been maintained, keeping understory open and creating snags (for nesting and roosting), or where small clearings created naturally (hurricanes, disease, or bark beetles) or artificially (clear-fell) and in which snags left standing; or forest-wetland ecotone where snags created by flooding. May breed in residential areas if snags or nestboxes, as well as mature living pines (for foraging), are available. Found also in pine-oak (*Pinus-Quercus*) woodland and in oak-hickory-pine (*Quercus-Carya-Pinus*) forests; in Florida may nest in cypress (*Taxodium distichum*) swamps and in prairies adjoining pine woodland. Will venture outside woodland to areas of scattered trees, and seedling pines in abandoned farmland; even investigates fence posts and telegraph poles along roads. Mainly lowlands and piedmont, usually below 150 m (90 m in Texas), but recorded at up to 670 m in Georgia and 550–600 m in South Carolina (although a rare accidental in mountains of Carolinas).

Food and Feeding. Food insects and spiders (Araneae), in winter mainly pine seeds; young fed mostly with animal matter, but occasionally also on pine seeds (after hard covering removed). May store pine seeds, using its bill to pound them into crevices in bark of a pine, but caches not large; has been observed apparently to use bark flakes to cover seed caches. Family-members tend to remain together through autumn and winter, and forage beyond the territorial boundary; these small groups may amalgamate to form single-species flocks (up to 24 individuals recorded), and routinely join mixed-species foraging flocks. Forages on trunks, limbs, smaller branches, twigs, cones, and needle clusters of pine trees, and usually spends majority of its time in upper third of trees, with apparent preference for cones, needle clusters and outer part of branches (this perhaps due especially to competition with other species in mixed flocks). Often hangs upside-down, exploring clusters of needles for insects or picking seeds from cones; occasionally visits the ground, or forages in deciduous trees, on old tree stumps, fence posts, telegraph poles or buildings, and will visit garden feeders to take suet and sunflower (*Helianthus*) seeds. Does not often hawk for insects, but adept at flycatching when insects are disturbed. Will deliberately prise off bark scales to reveal hidden prey. Occasionally uses a scale of pine bark as a wedge with which to pry off bark scales; usually drops this “tool” after removing a scale, but may remove 3–4 scales before dropping it, or may carry it from tree to tree.

Breeding. Season early Mar to mid-May, sometimes Feb in Florida, exceptionally mid-Jul in Georgia, but nest-hole excavation from late Feb (rarely, late Jan); occasionally double-brooded. May form permanent pair-bond. Sometimes breeds co-operatively, in various studies 20–60 % of pairs assisted by helper male (usually a second-year individual, and related to one of the pair), rarely by two or even three helper males; helpers assist in chasing intruders, cavity excavation, and nest construction and sanitation, feed female on nest and feed young. Male probably maintains permanent territory around nest-hole, chasing away other males (exceptionally, two pairs may share a cavity); pairs with a helper hold larger territory than simple pairs, but these larger territories (and those of non-breeding pairs) may overlap more extensively with those of neighbours. Nest constructed by both sexes, usually from pine-seed wings, also bark chips, grass and other vegetable fibres, lined with cotton, feathers, wool and seed wings, placed in cavity 0.15–28 m above ground (but usually low, c. 2–3 m) in partially rotten wood, usually stump or dead tree (with preference for pine), sometimes fence post, but sometimes no nest built (eggs laid on bare floor of cavity); excavates own cavity (or reuses old one), entrance hole typically c. 3–3 cm in diameter, the work predominantly by male, taking 1–6 weeks, and several holes may be started before final choice made; nestbox also used, and occasionally pre-existing natural hole (including cavity under bark), rarely old woodpecker (Picidae) hole; often selects site in clearing, along roadside, in windbreak, over pond or in field, sometimes well away from foraging area. Clutch 3–7 eggs, usually 4–6 (very rarely, 9), white or creamy, heavily spotted reddish-brown to lavender, mean size 15.3 × 12.1 mm; occasionally replaces lost clutches; incubation by female, fed on and off nest by male and by any helpers present, period average 14 days; chicks fed by both sexes, also by helpers, but brooded only by female, nestling period 18–19 days (rarely, to 23 days); juveniles not fully independent until 2–4 weeks after fledging. In some studies, pairs with helpers significantly more successful at fledging young than those without helpers.

Movements. Resident, with very limited post-breeding dispersal. Accidental in Wisconsin, New York (near Elmira) and Pennsylvania, also sight records Indiana and New Jersey.

Status and Conservation. Not globally threatened. Common throughout most of US range; uncommon in Arkansas, Tennessee, Maryland and Delaware, and rare in Oklahoma. Recorded densities vary from 0.25 to 4 pairs/10 ha; highest breeding densities in upper coastal plain of W South Carolina, W Georgia, C Florida and S Mississippi. Significant downward trend in numbers throughout range between 1966 and 1996; prior to 1980 decline confined to coastal flatwoods, particularly in Florida and Mississippi, but since 1980 significant declines have continued both in these flatwoods and in upper coastal plain, and has declined also on periphery of range in S Delaware, W Tennessee and SE Oklahoma; may have been extirpated in Missouri (although the two records from there may have involved vagrants, rather than breeding birds). In S Florida now largely absent from most

counties near and SE of L Okeechobee; pine forests in SE USA have been altered by commercial logging and other practices, and old-growth pine forest almost gone (replaced by even-aged stands of pines on short rotations). Degradation of habitat by fire suppression may also depress populations, as can fragmentation of habitat; this species’ weak flight and sedentary character make recolonization of distant fragments following local extirpations unlikely, and this could explain its absence from apparently suitable habitat at edge of range in S Tennessee, SE Missouri and S Florida (e.g. suitable habitat appears to exist in Everglades National Park, but it has failed to recolonize the area, which lies only 65 km S of current range). Conversely, is apparently expanding its range N in Georgia, and first recorded SE Tennessee in 1968, with population of 50–70 individuals by 1981. In W North Carolina, recent records from counties of Caldwell and Buncombe may indicate range expansion to W. Race *insularis*, confined to Grand Bahama (Bahama Is), is rare, with few recent records; was fairly common in late 1960s and 1970s, but numbers declined by over 95% between 1969 and 1993, this probably due to logging of Caribbean pine (*Pinus caribaea*).

11. Corsican Nuthatch

Sitta whiteheadi

French: Sittelle corse

German: Korsenkleiber

Spanish: Trepador Corso

Taxonomy. *Sitta whiteheadi* Sharpe, 1884, mountains of Corsica.

A member of a species group that contains also *S. ledanti*, *S. krueperi*, *S. villosa*, *S. yunnanensis* and *S. canadensis*, and all sometimes thought to form a superspecies. Present species formerly treated as conspecific with *S. villosa* and *S. canadensis*; close relationship with these two supported by recent data on mitochondrial DNA, which indicate also a more distant relationship to *S. krueperi* and *S. ledanti* (no *S. yunnanensis* material was available for analysis). Earlier taxonomic separation of present species from *S. canadensis* based on studies of vocalizations, together with those of breeding biology and behaviour. A nesting pair of nuthatches resembling present species and *S. villosa* found at 2000 m in Altai Mts of extreme S Siberia (at Aktru, S of Karay) in 2006; this could represent a remarkable range extension of either species, or an as yet undescribed species, but requires verification. Monotypic.

Distribution. Inland mountain ridges on Corsica (from Tartagine S to Ospedale and Mt Cagna).

Descriptive notes. 12 cm; 11.8–14.4 g. A small nuthatch with rather long bill and prominent broad white supercilium. Male in fresh plumage (autumn) has glossy black cap from forehead to nape (ill defined at rear), faintly buff-washed white supercilium (from nostril) to side of mantle and ending irregularly at rear, black eyestripe finely spotted white behind eye and less well defined at rear of ear-coverts (merging irregularly into mantle); upperparts, including lesser and median upwing-coverts, blue-grey; greater wing-coverts and flight-feathers dark grey-brown, tertials washed blue-grey on outer web, greater and primary

coverts, secondaries and inner primaries narrowly fringed blue-grey, primaries P3–P6 finely fringed blue-grey inward of emarginations, secondaries and inner primaries finely tipped white (only when fresh); central tail feathers dull blue-grey, other rectrices sooty black, tipped grey (widest on outermost feather), outer three pairs marbled with white subterminally, especially on inner webs; cheek, ear-coverts, chin and throat white, washed dirty buff, side of neck and underparts pale drab grey, variably tinged buff, especially on flanks, belly and undertail-coverts; underwing-coverts and axillaries whitish, median under primary coverts medium grey, base of primaries white (not strongly contrasting); in worn plumage (summer), crown slightly less glossy, upperparts duller and less blue, flight-feathers abraded and bleached paler, supercilium, throat, cheek and ear-coverts whiter, underparts duller, light greyish with little or no buff wash; iris dark brown, narrow white eyering; bill slate-black to grey-brown, more bluish at base of upper mandible, base of lower mandible pale grey to whitish; legs dark grey-brown or slate-grey, soles sometimes yellow. Female resembles male, but crown and ear-coverts medium blue-grey (as upperparts), dark feather centres largely or totally concealed but may show as slightly darker mottling on (usually) forecrown and forehead, especially in worn plumage (exceptionally, dull blackish forecrown); eyestripe grey and less well defined behind eye, supercilium and underparts tend to be greyer. Juvenile is as adult but slightly duller overall, with faint brown tips on greater upwing-coverts, pale base of lower mandible more extensive, legs paler grey; cap of very young male may be sooty black with no gloss, and juvenile female lacks blackish feather bases on forecrown. VOICE. Contact call a soft, whistled “pu”, singly or in groups of 5–6 notes, sometimes as rapid trilling “pupupupupu...”, especially immediately prior to or during flight; also gives thin, sometimes lisping “tsi-tsi-tsi” and nasal “pink”, often in irregular series; in agitation a hissing “psch-psch-psch...” and a nasal note like sound from toy trumpet, becoming louder and harsher in excitement or alarm; also a repeated harsh “chay-chay-chay” or “sch-wer sch-wer” similar to call of distant Eurasian Jay (*Garrulus glandarius*), and increasing in intensity as excitement heightens, when may lose harsh quality and become more musical. Song, fairly regularly in spring, a repetition of single clear, high-pitched note at c. 15 notes per second to produce rapid, sometimes quavering trill, “hididididid...”, also slower variant of pure, ascending whistled “dew” or “dui” notes at c. 10 per second; the two may be combined, as “dewdewdewdewdew-di-di-di-di-di”.

Habitat. Primarily forests of Corsican pine (*Pinus nigra*), characterized by heavy autumn and winter rainfall and rather dry summers; especially unmanaged pure stands of tall trees (some 300 years old, producing greatest quantities of seeds) with abundant standing dead and rotting trunks and occasional clearings. Lower densities (less than 20% of maximum density) in young forests, mature stands under heavy management, and where Corsican pines mixed with cluster pine (*Pinus pinaster*), beech (*Fagus sylvatica*) or silver fir (*Abies alba*), usually below 1000 m (but can reach high densities in stands of cluster pine at c. 800 m); densities low also above 1500 m, where trees scattered and stunted. In winter some dispersal, occasionally to cork oak (*Quercus suber*) forest, sweet chestnut (*Castanea sativa*) plantations and villages at lower altitudes, although still favours pines overall. Found at 750–1800 m during Apr–Oct, with breeding recorded at 760–1600 m, optimum 1000–1500 m; down to 300 m, and rarely even at sea-level, in non-breeding season.

Food and Feeding. Food largely insects and spiders (Araneae) during May–Aug, switching to seeds, especially those of Corsican pine, during rest of year. Forages in pairs and singly; outside breeding season, may join mixed-species flocks. Forages in manner of a tit (Paridae) in needle

clusters and among small branches, especially in spring and summer, also (particularly in winter) on trunks and larger branches. May hover to pick small items from cones etc., and can also flycatch. From late autumn to early spring (i.e. when cones are mature), and during sunny weather (i.e. when cones are open), extracts seeds from cones and caches them behind bark, or places seeds on thicker branches and covers them with fragments of bark or lichen; retrieves cached seeds in cold and wet weather. These stores probably essential to survival, especially in early spring when snow prevents access to pine cones.

Breeding. Season mainly Apr–May, and laying dates synchronous, generally at end Apr or in first ten days May; may be double-brooded. Mated partners remain on territory all year. Nest, built by both sexes, a coarse foundation of pine needles, wood chips and bark pieces, lined with hair, feathers, moss, lichen or plant fibres, placed in cavity 1.6–30 m above ground in medium-sized to large dead or dying Corsican pine, usually in dead pine stump (200–300 years old at time of death) 3.5–22 m high and well rotted; cavity generally excavated by birds themselves, work carried out by both sexes, majority of excavations exploit hole originally started by woodpeckers (Picidae), and some, in very rotten trunk, may have two entrances; living pine with rotting top occasionally used. Clutch 5–6 eggs, white, speckled reddish, especially at broader end, sometimes with light brown or dark violet-grey markings, mean size 17.3–13 mm; replacements laid if clutch fails; incubation by female, fed on nest by male, no information on duration of incubation period; chicks fledge after 22 days.

Movements. Resident. Territorial adults almost completely sedentary, probably a reflection of their seed-hoarding behaviour. Some dispersal in winter to slightly lower altitudes, usually by immatures and unmated adults; such movements most frequent following snowfalls, when recorded in valleys of C Corsica at 300–600 m, and even at sea-level towards W coast (at Calvi) in Oct and in E (Aleria plain) in Jan.

Status and Conservation. Not globally threatened. Restricted-range species: present in Corsican Mountains Secondary Area. Uncommon and somewhat local; occurs on inland mountain ridges from Tartagine S to Ospedale and Mt Cagna, with main concentrations around the mountains of Cinto, Rotondo, Renoso and Incudine; absent from Nebbio and Cap Corse. Population estimated at only 1570–2230 occupied territories (= breeding pairs) in early 2008; in 1981–1984 c. 2000 pairs calculated, on basis of average density of 0.85 pairs/10 ha in c. 24,000 ha of suitable forest. These figures represent marked decline from estimate of 3000 pairs in 43,750 ha of forest in late 1950s. Presence of old stands of Corsican pine appears to be key factor in survival of this species, and main factors limiting its abundance are fire (can destroy habitat for many decades) and removal of dead and rotting trees (used as nesting sites). Although large numbers of Great Spotted Woodpeckers (*Dendrocopos major*) can result in high predation of chicks, the woodpecker increases availability of suitable nest-sites. Species readily tolerates close proximity of houses, powerlines and traffic. Almost the entire global population of the species occurs within the Natural Regional Park of Corse (Corsica).

12. Algerian Nuthatch

Sitta ledanti

French: Sittelle kabyile

German: Kabylenkleiber

Spanish: Trepador de Kabila

Other common names: Kabyli/Kabylian Nuthatch

Taxonomy. *Sitta ledanti* Vieillard, 1976, Djebel Babor, Algeria.

A member of a species group that contains also *S. whiteheadi*, *S. krueperi*, *S. villosa*, *S. yunnanensis* and *S. canadensis*, and all sometimes thought to form a superspecies. Differs from others of group in being slightly larger and less restricted to coniferous forest. Recent evidence from mitochondrial DNA suggests that its closest relative is *S. krueperi*, with *S. whiteheadi*, *S. villosa* and *S. canadensis* more distantly related (no *S. yunnanensis* material was available for analysis). Monotypic.

Distribution. NE Algeria (Petite Kabylie mountain region).

Descriptive notes. 13.5 cm; 16.6–18 g. A medium-sized nuthatch prominent white supercilium and short, slender and sharply pointed bill; bill often appears upturned owing to rather straight culmen and distinct angle at gonys. Male in fresh plumage (autumn) has forecrown black, odd feathers faintly tipped grey, broad white or creamy supercilium from nostril to nape, gradually merging at rear with blue-grey of upperparts, some grey flecking in front of eye, dull black eyestripe from bill to rear ear-coverts (ill defined behind eye); hindcrown and upperparts, including side of neck, tertials and upwring-coverts, blue-grey, wing-coverts

diffusely tipped paler; flight-feathers sooty black, secondaries fringed blue-grey, outer primaries finely fringed pale grey at base, inner primaries and secondaries tipped white; central tail feathers blue-grey, other rectrices blackish with narrow blue-grey tips, subterminal white bar from outer web of T3 to T6, broadest on T6; cheek and ear-coverts white, washed buff and variably mottled blackish or dark grey, especially at rear; throat and underparts creamy pink or washed pinkish-buff, some grey feather centres showing on undertail-coverts; in worn plumage, cap pure black, supercilium purer white, eyestripe darker, also broader at rear, encompassing lower ear-coverts (where mottled off-white), upperparts duller and less blue, tail and flight-feathers bleached slightly paler, pale tips of wing-coverts and flight-feathers abraded, underparts orange-buff to creamy, washed pinkish-buff; iris blackish-brown, narrow whitish eyering; bill slaty black, base of cutting edge of upper mandible and basal half of lower mandible blue-grey; legs grey or dark grey. Female as male, but in fresh plumage most of crown and eyestripe concolorous with upperparts, blackish confined to diffuse spot on forehead; when worn, has variable black cap, although generally paler, rather less extensive and less well defined than male's. Juvenile has cap and eyestripe concolorous with upperparts, supercilium very poorly marked, upperparts paler and less blue than adult and underparts also paler; variation with sex and age not fully understood, black-capped juveniles once described but existence of this plumage strongly contested by subsequent observers; nevertheless, juveniles from a single nest can vary in head pattern (of a brood of three, one had black forecrown and resembled adult male, one resembled adult female, and third had crown grey and concolorous with mantle), and juveniles presumably sexually dimorphic. **Voice.** During foraging and in flight a quiet, soft, nasal "kna" (reminiscent of *S. canadensis* call), which can become inquisitive, nasal

"quuwee"; in excitement or territorial defence a harsh, rasping, "vschrr vschrr" or "schrr, schrr-schrr" and sometimes, when more agitated, a louder, even cawing "chwa-chwa-chwa". Other calls include nasal, inquisitive "du-wa, du-wa" or "qu-wa-di-wa". Song a stereotyped repetition of 7–12 similar notes, sometimes nasal, sometimes fluty, at 3–4 couplets per second, "quair-di, quair-di, quair-di..." or "verdi-verdi-verdi...", which can be slightly rising in pitch; sometimes somewhat faster, "du-wid-du-wid-du-wid...", or even more accelerated, each note almost monosyllabic and slightly higher-pitched, "vid-vid-vid..."

Habitat. On Djebel Babor (climate cool and humid, annual precipitation 2000–2500 mm, falling mostly in winter; up to 4 m of snow Nov–Apr/May), found in relict stand of montane forest with many epiphytic mosses and lichens; at 1200–1650 m forest dominated by deciduous Atlas oak (*Quercus tlemcenensis*), with significant proportion of Atlas cedar (*Cedrus atlantica*), from 1650 m to 1800 m percentage of cedar and Algerian fir (*Abies numidica*) increasing, and summit area at 1800–2004 m dominated by cedars, with small proportion of oak and fir; nuthatches occur above 1450 m, with highest densities above 1900 m, and much lower densities in pure stands of oak or cedar. A good mixture of tree species (thus a reliable supply of seeds) may be important for winter survival, while size and age of trees and hence amount of dead wood and epiphytes also important. Found from 350 m to summit (at 1121 m) in Guerrouch forest (in Taza National Park), which has rather warmer and drier climate (rarely experiencing frosts, annual rainfall 1000–1400 mm); at lower altitudes forest dominated by cork oak (*Quercus suber*) and at higher altitudes by Algerian chestnut-leaved oak (*Quercus castaneifolia*), with Algerian oak (*Quercus canariensis*) also prominent; good understorey of alder (*Alnus*), cherry (*Prunus*), willow (*Salix*), ash (*Fraxinus*) and maple (*Acer*). Apparently found at 900–1400 m in Tamentout forest (lying along a ridge which culminates in peak of Tamesguida, 1626 m) and nearby Djimla forest (rises to 1532 m), mostly in Algerian oak and Algerian chestnut-leaved oak above 1000 m, rarely (and only in Tamentout) in cork oaks at lower altitudes. Range of habitats utilized, and clear preference for foraging in oaks, suggest that this species' distribution is determined by availability of forest, rather than by a very specific ecological niche, and that it is not dependent on Algerian fir or Atlas cedar as suggested following its initial discovery, at Djebel Babor (perhaps the least typical site).

Food and Feeding. Food probably mainly insects and spiders (Araneae) in summer; diet in winter largely seeds and nuts (four seed-producing tree species on Djebel Babor appear to ensure relatively constant supply); nestlings fed with insects, spiders and conifer seeds. In summer forages in twigs and outer branches of oaks (90% of observations in Jun), also in firs and cedars; searches underside of branches and flowers in manner of a tit (Paridae), but seldom comes to ground, and not known to flycatch; a pair with territory in stand of cedars flew long distances to forage in oaks for brood-feeding. In winter forages on trunks, branches and twigs of moss-laden or lichen-covered oaks (45% of observations in Mar), cedars (32%) and firs (22%), often knocking off chips of bark to reveal food items. Also stores seeds in lichen-covered branches and thick cushions of epiphytic mosses for later retrieval (even as late as breeding season). Defends winter territory, and may join mixed-species foraging flocks.

Breeding. Season May; probably single-brooded. Strongly territorial in breeding season, both sexes defending territory boundaries. Nest constructed from wood chips, leaves, feathers and hog bristles, placed in hole in dead or dying tree, usually in dead branch 3–15 m above ground, on Djebel Babor usually in fir, sometimes in oak or cedar, and often uses cavity produced by snow damage to lower crown of tree; may excavate own hole or take over abandoned hole of woodpeckers (Picidae), entrance often relatively large; of nine nests located in 1978, one abandoned nest-site had entrance extensively "plastered" with clay and rotten wood (confirmation that species does, at least occasionally, plaster up nest hole is required). No information on clutch size, but broods of 2–4 young recorded; incubation probably by female alone, no information on duration; young fed by both parents, probably leave nest after 22–25 days; juveniles continue to be fed for 1–2 days after fledging, but become fully independent relatively quickly, wandering into adjacent territories after just 7 days.

Movements. Resident. On Djebel Babor may undertake some altitudinal movement and limited post-juvenile dispersal, but downslope movement inhibited by treeless zone below breeding area; presumed to spend winter months on Babor, despite deep snow (seen in breeding area in mid-Apr, with snow still 2–3 m deep), perhaps aided by cached food supplies. No information on possible movements by populations elsewhere in range (Guerrouch, Tamentout and Djimla).

Status and Conservation. ENDANGERED. Restricted-range species: present in North Algerian Mountains Secondary Area. Discovered as recently as 1975, on Djebel Babor. Has small population, estimated at 250–999 individuals, within very small global range of 240 km². Known from four localities, habitat at one of which severely threatened and declining in quality. Forest on Djebel Babor covers c. 1300 ha, but optimum habitat extends for less than 250 ha in summit area, and population estimated at c. 80 pairs in 1982; highest densities, of 3–4 pairs/10 ha, in summit forest above 1900 m, but much lower in pure stands of oak or cedar (c. 0.5 pairs/10 ha). Forested massif of Guerrouch protected by Taza National Park (total area 3807 ha); surveys in Taza in summer 1989 (when species first located there) revealed 91 individuals in 800 ha, extrapolation from which gives figure of 364 individuals in the 3197 ha of forest within park (total forest cover on Guerrouch estimated at 8577 ha in 1955, and this species found also to SW of park boundary); densities at Guerrouch exceed 3 pairs/10 ha. Tamentout forest covers area of c. 9500 ha and Djimla forest c. 1000 ha; no information on these two populations (both discovered in 1990), but, with combined total area of 10,500 ha, they may hold a summer population of c. 1200 individuals if density is similar to that at Guerrouch. Searches elsewhere in region have failed to find any more populations of this nuthatch. Although the area has national park status, summit forests of Djebel Babor are threatened, but their conservation has received some attention since discovery of the species. Nevertheless, grazing hinders regeneration, wood-cutting removes potential nest-sites, and fires result in replacement of rich mixed forest by poorer cedar-dominated succession. All three factors reduce quality of habitat for this species, as well as reducing total forest area; further, construction of a motorable track in 1970s has led to erosion, increased risk of fire, and fears of disturbance by tourists. Guerrouch population not considered at risk, as national park is fully protected. At Tamentout and Djimla, overgrazing has led to impoverished understorey and poor regeneration, and deforestation throughout region is rife.

13. Krüper's Nuthatch

Sitta krueperi

French: Sittelle de Krüper

German: Türkenkleiber

Spanish: Trepador de Krüper

Taxonomy. *Sitta krüperi* Pelzeln, 1863, Smyrna (Izmir), west Turkey.

A member of a species group that contains also *S. whiteheadi*, *S. ledanti*, *S. villosa*, *S. yunnanensis* and *S. canadensis*, and all sometimes thought to form a superspecies. Present species has sometimes been treated as conspecific with *S. canadensis*, at least, but differs from that and all others of group in having rufous breast patch (significant in courtship and territorial display) and relatively large difference between adults and juveniles. Recent evidence from mitochondrial DNA suggests that its closest relative is *S. ledanti*, with more distant relationship to *S. canadensis*, *S. whiteheadi* and *S. villosa* (no *S. yunnanensis* material was available for analysis). Monotypic.

Distribution. Extreme E Greece (Lesbos), Turkey (except most of C & E), extreme SW Russia (Krasnodar region and N watershed of NW Caucasus) and S Georgia (foothills of Kuzey Anadolu Mts).

Descriptive notes. 12.5 cm; male 10–14.3 g. A medium-small nuthatch with black forecrown, white supercilium and distinctive rufous breast. Male in fresh plumage (autumn and winter) has forecrown black with slight blue gloss, sharply demarcated from rear crown; supercilium (from nostril to rear of ear-coverts) white, occasionally mottled grey, black eyestripe well defined on lores, broken and less distinct behind eye; upperparts, including lesser and median upwearing-coverts and tertials, medium blue-grey, dark centres of coverts fully concealed, tertials tipped slightly paler; greater secondary coverts and primary

coverts blue-grey, inner webs dark brown, flight-feathers and alula dark brown-grey, smaller feathers of alula, secondaries and inner primaries fringed pale blue-grey, P3–P6 fringed blue-grey inward of emargination; central tail feathers dark brown, tinged blue-grey (especially on outer web), other rectrices black, tipped blue-grey (broadest on outermost rectrix), often some white subterminally on outer two feather pairs; cheek, ear-coverts, side of neck and throat white; centre of breast deep rufous, side of breast and flanks light blue-grey, lower breast to vent pale grey, often washed buffish-brown on side of breast, flanks, thighs and vent; undertail-coverts chestnut, tipped whitish; underwing-coverts and axillaries off-white, longer under primary coverts tipped sooty-black; in worn plumage, cap, supercilium and eyestripe duller and less well defined, cap sometimes with grey mottling, upperparts duller and less blue, flight-feathers (tertials) browner, breast patch paler and less well defined, underparts darker with slight buff tinge, some grey mottling on belly and vent, white tips on undertail-coverts worn away; iris dark cinnamon or brown, narrow white eyering; bill dark horn-grey, cutting edge of upper mandible at base and entire base of lower mandible blue-grey; legs grey-brown or dark grey. Female is as male, but black forecrown duller and less well defined at rear, eyestripe paler, breast on average paler and more orange-rufous, and lower breast washed buff; in worn plumage differences (apart from buffish lower breast) less obvious. Juvenile is distinctive, much dingier than adult, lacking black on forecrown (forehead may be marginally darker than rest of crown), with supercilium and eyestripe poorly marked, breast patch pale rufous and poorly demarcated from dirty brownish belly, bill dark horn-brown, base of lower mandible tinged pink, gape yellow; sexes probably similar, but breast patch of juvenile male possibly darker and more rufous than that of young female. Voice. Very vocal. In excitement or alarm gives subdued, often rather quiet harsh or hissing “cha” or “scharr”, like call of distant Eurasian Jay (*Garrulus glandarius*), becoming louder and given in series as agitation mounts, and may be accelerated into excited, scolding, churring rattle; other calls include soft “pwit”, and “doid” or “dwi” similar to call of European Greenfinch (*Carduelis chloris*); in flight, a nasal “jek”. Song, throughout year (most frequently in spring), a trill given at varying speeds and with differing inflections, in its basic form a shrill, rippling repetition of simple notes at c. 8 per second, “pip-pip-pip-pip...” or “veet-veet-veet...”, lasting 4–8 seconds; in more complex form comprises two alternating notes repeated more slowly (c. 4–6 couplets per second), although still high-pitched and yodelling, for 3–4 seconds, “yu-di yu-di yu-di” or “wicka-wicka-wicka...”.

Habitat. Closely associated with Turkish pine (*Pinus brutia*). In Turkey, found in forests of Turkish pine at lower altitudes and in forests of spruce (*Picea*), fir (*Abies*), pine, cedar (*Cedrus*) and occasionally juniper (*Juniperus*) at higher altitudes; in both dense and open woodland, and sometimes in areas of scattered trees; mostly at 500–1000 m, locally down to near sea-level in W & S and up to 1700 m on Ulu Dag, and at 500–1800 m (exceptionally, to tree-line at 2500 m) in Taurus Mts and Black Sea coastlands. On Lesbos dependent on Turkish pine, although will nest in broadleaf trees if pines nearby; breeds at 200–700 m, mostly above 400 m, and recorded down to sea-level in late summer and winter. In Caucasus region found in fir (favouring old-growth forest), mixed woodland, e.g. beech–fir (*Fagus–Abies*), pines (perhaps especially where a good mixture of fir or spruce) and, at much lower densities, in maple (*Acer*) parkland, and has been recorded as breeding in stand of aspen (*Populus tremula*); at 1000–2000 m, but at 150 m on Black Sea coast near Sutchumi (in a woodland park with introduced conifers).

Food and Feeding. Food largely insects and spiders (Araneae) in breeding season, switching to seeds of Turkish pine and other coniferous trees in autumn and winter; nestlings fed entirely with animal matter. Found singly and in pairs in breeding season; at other times in parties of 2–5 individuals and may join mixed-species foraging flocks. Normally forages in tree-tops among smaller branches and cones, but will utilize all levels of vegetation, including bushes, and sometimes feeds on ground. Inserts the bill between the scales of cones to pull out the seeds, which are then taken to bark crevices and hammered. Arthropods sometimes taken in flight. Will store food for future consumption; as pine seeds can be extracted only when cones partly open, may rely largely on cached food in wet weather (when cones temporarily close); territory probably maintained through winter to guard hoards.

Breeding. Season early Apr to mid-May (depending on altitude and locality) on Lesbos and in Turkey, and Apr–May in Caucasus; probably single-brooded. During breeding season territory vigorously defended, usually by song-duels at territory boundary; rufous breast expanded in threat displays. Nest, built largely by female, a foundation of coarse bark chips, rotten wood and cone scales, lined with a pad of moss, bark fibres, hair, wool, fur and feathers, placed up to 24 m above ground in hole in tree, usually a conifer; excavates own hole in dead trunk or branch or, more frequently, cleans out existing cavity, the work being undertaken mainly by female; eggs sometimes laid on top of a stump or even in pile of twigs in a fork (perhaps only when holes not available); smallest territory on Lesbos 3–4 ha. Clutch 5–7 eggs, creamy white with rusty or purplish spots, often concentrated at larger end, mean size 17 × 13 mm; incubation by female, fed on and off nest by male, period c. 14–17 days; chicks brooded by female, fed by both parents, fledging period 16–22 days.

Movements. Resident, with some post-breeding dispersal. In Turkey noted at Çamlıca hills (in Istanbul) in autumn, and on Black Sea coast at Kizil İrmak delta in spring (late Apr). Some seasonal altitudinal movements, perhaps involving mostly immatures, and on Lesbos recorded down to sea-level in late summer and winter. In Caucasus some descend into montane broadleaf woodland, others reach foothills, and even locally Black Sea coast (in mixed woodland and regularly in conifer arboretum at Sochi, and Kolkhida forests of W Georgia). Many remain near high-altitude breeding

grounds throughout winter. A flock of 15–20 individuals recorded in Sept, suggesting unusual dispersal. Vagrant in mainland Greece.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common throughout range. Estimated population in Turkey 60,000–120,000 pairs, in Russia 20,000–50,000 pairs, and in Greece (Lesbos) 200–600 pairs; numbers in Georgia unknown. In Caucasus, densities vary from 4 pairs/km² in maple parkland to 48 pairs/km² in fir forest and 50–90 pairs/km² in mixed forest. Overall, numbers were stable during 1970–1990, but the two largest populations (in Turkey and Russia, which together hold more than 95% of global population) both declined by over 20% in period 1990–2000. In Turkey, increase in tourism has placed great pressure on old coniferous forests, especially in coastal regions, where the species was once numerous; urbanization and the construction of summer houses a growing problem throughout Mediterranean region. Population on Lesbos believed to be stable, although commercial resin extraction has reduced the number of old trees suitable for nesting.

Bibliography. Albayrak & Erdogan (2005, 2006), Anon. (2007i), Cramp & Perrins (1993), Delin & Svensson (1988), Dementiev *et al.* (1954a, 1970), Frankis (1991), Hagemeijer & Blair (1997), Handrinos & Akriotis (1997), Harrap & Quinn (1996), Kumeriove (1958), Leonovich *et al.* (1996a), Löhr (1962), Matthysen (1998), Neufeldt & Wunderlich (1984), Roselaar (1995), Vaurie (1959).

14. Chinese Nuthatch

Sitta villosa

French: Sittelle de Chine

German: Chinakleiber

Spanish: Trepador Chino

Other common names: Snowy-browed/Black-headed Nuthatch

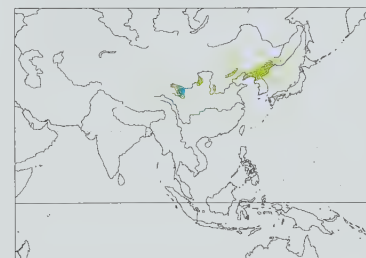

Taxonomy. *Sitta villosa* J. Verreaux, 1865, China north of Beijing.

A member of a species group that contains also *S. whiteheadi*, *S. ledanti*, *S. krueperi*, *S. yunnanensis* and *S. canadensis*, and all sometimes thought to form a superspecies. Present species formerly treated as conspecific with *S. whiteheadi* and *S. canadensis*; close relationship with these two supported by recent data on mitochondrial DNA, which indicate also a more distant relationship to *S. krueperi* and *S. ledanti* (no *S. yunnanensis* material was available for analysis). A nesting pair of nuthatches resembling present species and *S. whiteheadi* found at 2000 m in Altai Mts of extreme S Siberia (at Aktru, S of Karay) in 2006; this could represent a remarkable range extension of either species, or an as yet undescribed species, but requires verification. Geographical variation partly clinal, birds in W part of range largest and darkest below and those in E smallest and palest. Three subspecies recognized.

Subspecies and Distribution.

S. v. bangsi Stresemann, 1929 – NC China in NE Qinghai (Daban Shan), adjacent C & S Gansu (E Qilian Shan S to N Min Shan), extreme N Sichuan and, probably disjunctly, W Ningxia (Helan Shan). *S. v. villosa* J. Verreaux, 1865 – NE China in N Hebei (S at least to mountains N of Beidaihe and Eastern Qing Tombs), Beijing Municipality and W Shanxi (Kelan S to Zhongtiao Shan).

S. v. corea Ogilvie-Grant, 1906 – Russian Far East (S Ussuriland S of 45° N, and possibly S Sakhalin), extreme N Korea (around Mt Paektu, in Changbai Shan, and scattered from N Hamgyong, Yanggang and Pyongan S to Pyongyang) and NE China (S Jilin and S Liaoning).

Descriptive notes. 11.5 cm; 8–11 g. A small nuthatch with dark cap and pale supercilium; slender, sharply pointed bill may give distinct upturned effect owing to straight culmen. Male nominate race in fresh plumage (Aug to mid-winter) has crown and nape black, slightly glossy, upperparts blue-grey; white supercilium faintly washed buff, flecked blackish over bill and at rear (supercilia barely meet over bill), extending broadly onto side of mantle, narrow blackish eyestripe from nostril to rear of ear-coverts with some pale grey feather tips (may largely obscure black bases); upwearing-coverts dark brownish-grey (greater coverts

washed blue-grey), fringed medium blue-grey, primary coverts and alula dark grey, fringed medium blue-grey; tertials and flight-feathers dark brownish-grey, tertials washed blue-grey, secondaries and inner primaries fringed blue-grey, primaries P3–P6 fringed paler and greyer (inward of emarginations only); central tail feathers dull blue-grey, other rectrices sooty black with mid-grey tips (tip tiny on T2, extensive on outer web of outermost rectrix), outermost rectrix with whitish subterminal area on outer web extending diagonally onto inner web, and faintly indicated on T5 (especially on tip of inner web); cheek, ear-coverts, chin and upper throat white, grading to buffy white on lower throat and side of neck, and pale greyish-buff (or pale pinkish-buff with grey wash) on remainder of underparts, slightly cleaner and more cinnamon on flanks and belly; thighs dark grey, tipped dull buff; axillaries drab buffish, underwing-coverts medium to dark grey, finely tipped paler; longer under primary coverts and base of primaries white; in worn plumage, upperparts duller and slightly less blue, flight-feathers bleached and worn paler, but underparts little changed; iris brown or dark brown, narrow whitish eyering; bill slaty black, base of lower mandible grey-blue; legs dull blue-grey or brownish-grey. Differs from remarkably similar *S. whiteheadi* mainly in somewhat brighter plumage, especially below; easily distinguished from *S. przewalskii* (which has similar rich cinnamon underparts) by head pattern. Female as male, but cap grey and only slightly darker than mantle (with plumage wear, becomes darker and more contrasting sooty grey, especially on forehead, and sometimes entire crown sooty black and gradually merging with blue-grey nape), supercilium slightly narrower, eyestripe duller and less well defined (more extensively flecked pale grey), upperparts duller, fringes of wing feathers brown-tinged, underparts slightly duller and darker. Juvenile is marginally distinct, male has cap duller and less glossy black than adult (but blacker than even darkest-crowned female), and rather darker and richer cinnamon underparts. Race *bangsi* is largest, with underparts brighter, in fresh plumage male orange-cinnamon below (slightly darker than juvenile male of nominate), female dull buffy cinnamon, fringes of wing feathers tinged cinnamon; *corea* is marginally the smallest in size and palest, greyish-smoky, below. Voice. Three basic calls: type 1 is a prolonged, harsh, rasping “schraa, schraa” similar to call of Eurasian Jay (*Garrulus glandarius*), given (in agitation or excitement) singly or in irregular series at intervals of 0.3–1 second (then sometimes becoming shorter and higher); type 2 is various quiet conversational short notes, more melodic or piping, and repeated in series e.g. “wip, wip, wip...”, or “quip-quip-quip-quip”, becoming thin, squeaky “quit, quit, quit...”, series very variable in duration and in number of notes (short or long, and individual notes repeated either very rapidly or at irregular intervals); type 3 is short nasal “quii, quii” at varying pitches, again sometimes in long series, either very rapidly or at irregular intervals. Song, from tree-tops (while flicking wings and tail), a rapid repetition of c. 5–30 type-2 calls, pure and melodic upwardly inflected whistles increasing in volume during first part of series, c. 7 notes per second but each note easily distinguish-

able, series lasting c. 1.5–2.25 seconds, may be introduced by higher note, “tsi-pui-pui-pui-pui...”. A variant is a much flatter, less musical and more monotonous rattle, “duiduiduidui...” (c. 12 units per second). Another variant (“slow song”) is slow repetition of 7–11 “quit” notes.

Habitat. In China inhabits coniferous forest, probably chiefly pine (*Pinus*) and spruce (*Picea*), sometimes with mixture of oak (*Quercus*) and birch (*Betula*), predominantly in hills; recorded in N Sichuan at 2100–2600 m, in Jilin (Changbai Shan) 780–2100 m (with breeding noted at 780–1800 m), and breeds in Beijing area at 1300 m; recorded also from conifer plantations at lower altitudes and perhaps breeds also in relict stands of trees around tombs and temples in lowlands, and certainly disperses to plains level in winter. In SE Russia (Ussuriland) and N Korea associated with relict plateau larch forest (*Larix dahurica*), mixed tree stands and, in extreme N, also with *Picea obovata* at 600–1500 m (600–750 m in Ussuriland) and foothill pinewoods (mainly *Pinus densiflora*) below 600 m (in N Korea), but recorded as breeding also in city park of Pyongyang.

Food and Feeding. Food in summer almost exclusively insects, in winter (through to at least May) pine seeds and other seeds also taken; young fed entirely with animal items. In studies in China, diet in Apr–Aug consisted of 98.5% insects, mainly beetles (Coleoptera), Hymenoptera, Lepidoptera, heteropteran bugs, homopteran bugs (including Aphidina, Cicadina), Neuroptera, flies (Diptera). In winter found in pairs, often in mixed-species foraging flocks. Forages in tops of moderately tall trees, on branches and twigs, clinging upside-down to small cones while rapidly fluttering wings; less often on trunks. Sometimes flycatches, and dives after dropped items. Larger insects held down with foot and torn apart with bill. Habitually hoards food.

Breeding. Recorded in Apr, with nest-building in Mar, in NE China and Korea; normally single-brooded, perhaps occasionally a second brood (copulation by nesting pair observed in May). Nest built by both sexes, taking 7–8 days, bowl-shaped, made from plant fibres, feathers and grass, placed in cavity in tree (conifer or broadleaf), rotten stump or old building (e.g. damaged wooden roof of pagoda), in N Korea mainly in larch or old chestnut (*Castanea*) but also in poplar (*Populus*), oak and cherry (*Prunus*), height above ground 0.3–14 m (maximum 7 m in one study, average of 13 nests 9.4 m in another); either excavates own hole or uses abandoned woodpecker (Picidae) hole, diameter of entrance c. 35 mm; during incubation stage, male habitually brings mud to sitting female, and she uses this to repair inside wall of nest-hole (although species appears not to daub entrance hole with mud or resin). Clutch 4–9 eggs, usually 5–6, white, marked with reddish-brown, size 15–17 × 12.5–13 mm; incubation by female, fed on nest by male, period 15–17 days; chicks fed by both sexes, fledge after 17–18 days.

Movements. Summer visitor in SE Russia (Ussuriland), arriving mid-May; regular on passage in May on Bol'shoy Pelis, in Zaliv Petra Velikogo (Peter the Great Bay), off S Ussuriland. Apparently a summer visitor also to breeding areas in N Korea (some post-breeding dispersal into surrounding area), and in Changbai Shan (Jilin) and perhaps other areas of NE China, but possibly moving only to lower altitudes or dispersing short distances in winter; thus, in Hebei disperses to lowlands, occasionally to coastal areas (e.g. near Beidaihe). In remainder of range in China resident, with some altitudinal movements, and some erratic dispersal in winter; vagrant or winter visitor in S Shaanxi (Qin Ling Shan). Very rare non-breeding visitor in S Korea, mainly Oct–Mar, only recent record from Kwangnung Experimental Forest (near Seoul), in Mar 1968.

Status and Conservation. Not globally threatened. Common to fairly common in much of range; rare in Russia (Ussuriland). Status on Sakhalin unclear, one record, in May 1983, of a pair near Yuzhno-Sakhalinsk, in far S of island; female seen to enter a tree cavity, but this contained no nest material, and male was singing nearby. May sometimes be overlooked as a result of its preference for dense vegetation in canopy of coniferous trees. Fairly common in China, although densities not high, and confined to remaining areas of pine forest in hills; deforestation has reduced population of this nuthatch throughout much of range. In N Korea, common around Mt Paektu but rare farther S. Rare in Ussuriland, where population unlikely to exceed 20–30 pairs and recent systematic searches detected only 2–3 pairs; suitable habitat covers no more than 30–40 km², and surviving areas are being degraded by fire and logging.

15. Yunnan Nuthatch

Sitta yunnanensis

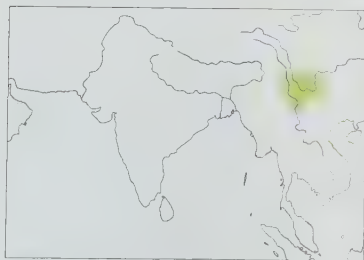

French: Sittelle du Yunnan **German:** Yünnankleiber **Spanish:** Trepador de Yunán
Other common names: Black-masked Nuthatch

Taxonomy. *Sitta yunnanensis* Ogilvie-Grant, 1900, near Wei Yuan, south Yunnan, China.

Usually considered a member of a species group that contains also *S. whiteheadi*, *S. ledanti*, *S. krueperi*, *S. villosa* and *S. canadensis*, and all sometimes thought to form a superspecies; differs, however, from others of group in that crown of male is concolorous with upperparts. Alternatively, sometimes thought to represent a link between that group and the “*S. europaea* superspecies” (containing also *S. nagaensis*, *S. cashmirensis*, *S. castanea*, *S. cinnamoventris* and *S. neglecta*), but as yet no DNA evidence to lend support to either argument. Monotypic.

Distribution. S China, from extreme SE Xizang (Zayu and Zhuwagan) E to S Sichuan (S from Yajiang) and S to W & C Yunnan and W Guizhou.

Descriptive notes. 12 cm; 7.5–13 g. A small nuthatch with slender, slightly upturned bill, narrow supercilium and broad long black eyestripe. Male in fresh plumage (Aug to spring) has whitish lower forehead and narrow supercilium extending to rear of ear-coverts, black eyestripe from nostril to side of mantle, broad (c. 5 mm) at rear, sometimes invaded with grey behind ear-coverts; crown and upperparts, including tertials and upperwing-coverts, medium grey-blue, often some paler feather centres visible on nape and upper mantle, inner webs of tertials greyer, grey inner webs of greater coverts fully concealed; alula,

primary coverts and flight-feathers dark grey-brown; smaller feathers of alula, primary coverts, inner primaries and secondaries fringed grey-blue, primaries P3–P6 fringed pale grey-blue inward of emargination; central tail feathers grey-blue (as upperparts), other rectrices blackish, broadly tipped blue-grey (extending along fringe of outer web), amount of white in tail variable, some individuals having T4–T6 with white triangle subterminally on fringe of inner web, T6 narrowly fringed white on inner web, others having a much larger subterminal white spot on inner web of T4–T5 and narrow broken diagonal subterminal bar across both webs of T6; chin, cheek, lower ear-coverts and side of neck white (forming contrasting line below dark eyestripe); throat and

underparts clean pale pinkish-buff, flanks and vent washed greyer, thighs dark grey, tipped pale pinkish-buff; axillaries light grey, underwing-coverts sooty grey, longest under primary coverts and base of primaries contrastingly whitish; in worn plumage, whitish feather tips forming supercilium abraded (on forehead reduced to few white flecks, sometimes entirely absent), eyestripe broader and more prominent (and black feather bases on forehead revealed), upperparts duller and less blue, wing and tail very abraded (but grey-blue fringes on flight-feathers present until at least May), underparts dirty pale buff-grey or greyish-white (when very worn, dark feather bases visible and underparts very dingy); iris dark brown, narrow white eyering; bill grey-black, yellowish-horn base of lower mandible (in museum specimens); legs grey-black. Female as male, but eyestripe on average less intensely black and underparts slightly duller and greyer, less pure pale pinkish-buff. Juvenile is duller than adult, with supercilia faint and not meeting on forehead (and sometimes almost lacking), eyestripe similarly reduced or absent, cheek patch dirty grey-white (rather than pure white), throat whiter, underparts dull greyish-cinnamon (not so pale as worn adult), bill considerably shorter, yellowish-horn base of lower mandible more extensive. **VOICE.** Rather vocal. Calls include nasal “nit” or “kni”, a shorter, more abrupt and higher-pitched (although still nasal) “tit”, an abrupt squeaky “pit” and a low nasal “toik”, all these given singly, but “nit” call sometimes in couplets as full “nit-nit” or abrupt nasal “chit-chit”, also often in series of 4–10 units at 5–6 notes per second, “kni-kni-kni...”, variations including purer, thinner and more peevish “kit-kit-kit...”, clearer and more piping “pi-pi-pi...”, and more nasal (but relatively high and weak) “niew-niew-niew”, each unit falling slightly in pitch. Other calls include harsh, scolding “schri-schri-schri...” (or “szi-szi-szi...”), similar to call of Eurasian Jay (*Garrulus glandarius*), which may grade into high, strident nasal “ziew-ziew-ziew...” (similar to sound made by squeaky toy) in series at c. 3 calls per second; “ziew” calls quite well separated or may be run together into cacophony of sound, and sometimes shortened to “zi”. Related calls include full explosive nasal “quit-quit-quit”, singly or in groups of 2–3 units, harsher and emphatic nasal “schu-schu-schu”, and thinner upwardly inflected nasal “tui-tui-tui”.

Habitat. Open mature pine (*Pinus*) forest with little undergrowth or scrub, apparently avoiding denser stands of spruce (*Picea*) and fir (*Abies*). Occasionally forages in relatively small pines, even as short as 2–3 m, in open forest and among scattered trees. Found at 2440–3400 m, sometimes to 3960 m, in summer; some movement to lower altitudes in winter, when recorded in Guizhou at 1670 m in Mar and c. 2750 m in Nov, and in Yunnan noted at 1200 m in Gaoligong Shan in Feb and 2000 m at Shuangbai in Sept, but also at 2600–4000 m in Nov–Jan.

Food and Feeding. Little information. Food insects. Frequently forages among needle clusters of pines in manner of a tit (Paridae).

Breeding. Female in Guizhou on 9th Mar was near to laying, and juveniles found from 21st May onwards. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Yunnan Mountains EBA. Locally common. Occurs at few sites on edge of range, e.g. in W Guizhou recorded only from Shuicheng (two individuals at Tuoda forest, 60 km NW of Weining, in Nov 1987). Has disappeared from several localities where recorded in early 20th century. Is presumably continuing to decline as a result of logging and forest fires, and, although this species does appear able to adapt to degraded and secondary forest, it could be dependent on mature pines for nesting; detailed ecological studies needed.

Bibliography. Anon. (2007i), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Collar *et al.* (2001), Dickinson *et al.* (2006b), Harrap & Quinn (1996), Hornbuckle (2003), Matthysen (1998), Riley (1926, 1931), Stattersfield & Capper (2000), Vaurie (1957b).

16. Red-breasted Nuthatch

Sitta canadensis

French: Sittelle à poitrine rousse **German:** Kanadagleiber **Spanish:** Trepador Canadiense
Other common names: Red-bellied Nuthatch

Taxonomy. *Sitta canadensis* Linnaeus, 1766, Canada.

A member of a species group that contains also *S. whiteheadi*, *S. ledanti*, *S. krueperi*, *S. villosa* and *S. yunnanensis*, and all sometimes thought to form a superspecies. Present species formerly treated as conspecific with *S. whiteheadi* and *S. villosa*; close relationship with these two supported by recent data on mitochondrial DNA, which indicate that all three form a sister-clade to *S. krueperi* and *S. ledanti* (no *S. yunnanensis* material was available for analysis), with a genetic distance of approximately 10% between the two clades. Monotypic.

Distribution. Breeds from SE Alaska (E from Kodiak I) and S Canada (S from S Yukon, including Queen Charlotte I and Vancouver, N Saskatchewan and C Manitoba, and E to SC Quebec, S Labrador and Newfoundland, including islands of Prince Edward, Anticosti, and St Pierre and Miquelon), S in W USA (absent much of E Washington) to mountains in California (excluding immediate coast, but breeds irregularly Santa Cruz I) and Rocky Mts and Great Basin from W & S Montana (also isolated forests in E) S to C & W Colorado, E Arizona and S New Mexico, also W South Dakota (Black Hills) and irregularly SW North Dakota and N Nebraska; in E, breeds S to NE & E Minnesota, N Wisconsin, S Michigan, N Ohio, C Pennsylvania, S New Jersey and N Connecticut, extending S in Appalachian Mts to E Tennessee and W North Carolina.

Descriptive notes. 11.5 cm; male average 11 g, female average 10 g (summer, Maine), autumn migrants 8–12.7 g (New Jersey). A small nuthatch with conspicuous white supercilium. Male in fresh plumage (Aug–Jan) has crown and nape black, faintly glossed blue, forehead and supercilium whitish, extending to side of upper mantle, eyestripe (from extreme base of bill) black, extending to side of upper mantle (on some very broad at rear, connecting with rear crown, on others narrower and with white mottling on lower border and side of neck); upperparts, including lesser and median coverts, medium grey-blue, often some white

feather centres visible on uppermost mantle; greater upperwing-coverts and tertials dark brown-grey, broadly fringed grey-blue, flight-feathers, primary coverts and alula dark grey-brown, all but outer primaries narrowly fringed grey-blue, P3–P6 fringed pale grey inward of emargination; central tail feathers medium grey-blue as upperparts, other rectrices black, outer four pairs tipped blue-grey, outer three pairs with diagonal white subterminal bar (largest on outermost); chin, cheek, ear-coverts and side of neck pale buff to whitish, darkening to cinnamon-orange on breast and rufous-cinnamon on side of breast, flanks and belly to undertail-coverts, but colour of underparts very variable (from buffy white to ochre-cinnamon); underwing-coverts and axillaries whitish,

washed cinnamon, median under primary coverts dark grey, base of primaries whitish; in worn plumage, cap duller, upperparts duller and less blue, with more white mottling on nape, flight-feathers paler and browner, underparts paler and less richly coloured, dirty pale orange-buff; iris brown, narrow white eyering; upper mandible black, lower mandible pale blue-grey, darker towards tip; legs dusky. Female is as male, but in fresh plumage cap medium grey-blue to blackish-grey (in worn plumage forecrown may be dull black), eyestripe narrower, mottled grey when fresh but usually dull black when worn (and at all times often darker than cap), underparts on average paler and duller, more cinnamon-buff. Juvenile is rather similar to adult of respective sex, but has yellow base of lower mandible (changing to white after 2–4 weeks) and paler legs for short period after fledging, upperparts less bluish than fresh adult (sometimes a few black fringes), can have faint dark specks in supercilium, chin and cheek, greater upperwing-coverts may be faintly tipped brownish, underparts on average paler; juvenile male has cap duller and less well defined than adult, juvenile female has cap and eyestripe dull grey and concolorous with mantle (as feather bases grey, does not darken with wear). **Voice.** Commonest call a nasal, bleating or mewling “knair, knair, knair” or “yna, yna, yna”, like sound made by a toy tin horn (rather more nasal, less cawing, than equivalent call of *S. carolinensis*), usually far-carrying, but may be quiet and inconspicuous in absence of other nuthatches, and varies in pitch and inflection; may be repeated in rapid series (“k-k-k-k-k-...”) or in slow regular sequence (“yaaaaa, yaaaaa, yaaaaa”); from late winter onwards given by unpaired male from tall trees, and probably serves both territorial and courtship functions. When irritated or angry emits variable fast but slightly quavering notes, e.g. “hnhnhnhn...” or “nananana-...” or “biddy-biddy-biddy-...”, sometimes in long series, essentially a rapid repetition of call, which at high intensity sounds like an electric buzzer, and in heightened excitement becomes trilled “thiiiiirrrrr”. Contact call is a soft, conversational nasal “it”, “pit” or “het”. Other calls include “phew”, singly or in short series, in situations of emotional intensity and sometimes elaborated into a “song”; a “zee zee zee zee zee”, by male when scolding intruder near nest and when chasing rival; repeated “purp”, becoming “we-we-we” or “peep, peep, peep-...”, by food-soliciting female; also a variety of musical “songs” comprising low twitterings and medleys of notes, at greater volume and intensity by male when feeding mate or young, and more loudly during courtship or fights, e.g. quavering soft “tee-you-you-you” and “wee-wur-tee-teo-too-too-wee-r”.

Habitat. Breeds in most temperate coniferous and mixed forests, especially where spruce (*Picea*), fir (*Abies*), pine (*Pinus*), hemlock (*Tsuga*), larch (*Larix*) and cedar (*Cedrus*) present, less commonly in pure stands of pine and hemlock; found also in mixed woodland with strong coniferous element and, more rarely, in deciduous woodland such as American aspen (*Populus tremuloides*). Standing dead wood required for nesting. Across wide range of elevations, from near sea-level to montane forest, but in S of range suitable habitat usually montane or submontane; in California breeds at 760–3075 m in Sierra Nevada (although recorded in summer as low as 275 m in N Coast Range); breeds above 900 m in North Carolina and above 1060 m in Tennessee. In winter in same habitat, but away from breeding areas utilizes much wider range of habitats, including deciduous forest, orchards, scrub, riparian woodland, and parks, shade trees and gardens in suburban areas, although with distinct preference for conifers where available. Montane breeders may descend to lower altitudes in winter but, depending on food supply, may remain in montane coniferous forests throughout year, e.g. recorded mid-winter in Idaho at 1830 m and above. On migration can be found in very wide range of wooded habitats, even shrubs and isolated riparian woodland in desert areas, although appears still to prefer coniferous trees; in extreme situations sometimes found away from trees, foraging on rocks, cliffs and roofs or in weeds and long grass.

Food and Feeding. Diet in summer diet mainly insects, especially beetles (Coleoptera), and spiders (Araneae), and young fed exclusively with insects; in winter largely conifer seeds, but will take seeds also of other plants, e.g. sedges (Cyperaceae), and occasionally eats fruit. Often attracted to garden feeders. In summer usually in pairs, and partners remain together on territory throughout winter if food resources adequate; otherwise, wintering migrants found singly or in flocks, typically of up to 4 individuals, and both migrants and residents may join mixed-species flocks. Forages primarily in conifers, in mixed forest also in deciduous trees, spending most time in crown, on small branches, probing beneath flakes of bark, at base of needle clusters and in cones; much less frequently forages lower on trunks or on the ground, the last especially in autumn when searching for fallen seeds and arthropods. Extracts seeds from cones; wedges food item into a crevice and pecks it into smaller pieces. Sometimes indulges in aerial flycatching, particularly during non-breeding season. Stores food, especially conifer seeds but also arthropods, in bark crevices, in disused sapsucker (*Sphyrapicus*) holes or occasionally in ground, sometimes covering stored item with a scrap of bark; has been seen to stuff seeds into cracks on granite wall very high above valley floor in Yosemite National Park, in California. In regions where species is resident, food caches are probably critical for overwinter survival.

Breeding. Season mid-Apr to late Jun; normally single-brooded, only one recorded case of two broods being reared. Pairs on breeding grounds, and territorial during breeding season; partners

stay together on territory throughout year if food resources allow, and remain mated for more than one season. Nest, built by female with some help from male, a bed of bark chips, pine needles, grass or rootlets, often lined with hair, fur, feathers, fine grass or shredded bark, placed 0.6–37 m (usually 2–12 m) above ground in cavity in tree; excavates own nest-hole, preferring standing dead tree, less often partially dead or live tree, either deciduous or coniferous, or sometimes existing cavity (only rarely nestbox) used, female selects site but unmated territorial male may initiate excavation of up to four different cavities and sing from these potential nest-sites; excavation by both sexes, female undertaking most of work, male typically perches nearby and brings food to her while she excavates; when nest completed, regularly smears entrance and trunk around it with sticky resin from balsam fir (*Abies balsamea*), spruce or pine, usually employing bill but sometimes using small piece of bark as applicator, fresh globules of pitch brought by both sexes until young fledge (during incubation stage, male applies resin primarily to outside of cavity entrance, female primarily to inner walls of entrance), resin may be thick enough to flow down trunk (pitch presumably discourages predators or nest-hole competitors); adults avoid pitch by flying straight in to nest (rarely, found dead, stuck to resin), and when young about to leave nest adults cover entrance floor with litter or fur (presumably to neutralize pitch and ensure safe passage for young). Clutch 2–8 eggs, usually 6, creamy white, sometimes pinkish-white, variably spotted reddish-brown, mean size 15.7 × 12 mm; incubation by female, fed both on and off nest by male, period 12 days; chicks fed by both sexes, leave nest at 18–21 days, remain with parents for at least two weeks after fledging.

Movements. An irruptive migrant, winter distribution and abundance dependent on crop of spruce, fir and pine seeds; generally has two-year cycle, although invasions sometimes in consecutive years. In years with good cone crop in N, the “centre of gravity” of population shifts S only slightly, with records as far N as SE & S coastal Alaska (rare; also casually in C Alaska) and, in Canada, NC Alberta, C Saskatchewan, S Ontario, S Quebec and throughout Maritime Provinces; also, montane populations remain at higher altitudes. In years of crop failure, exodus from breeding areas takes place, and can reach extreme S California, lowlands of S Arizona and S New Mexico, S Texas (occasionally as far S as Rio Grande delta), Gulf Coast and N Florida; degree to which birds penetrate S parts of USA variable, large numbers reaching Gulf Coast (where otherwise uncommon) every 5–10 years, but largely absent from Great Plains and a rare visitor to N Mexico (N Baja California, two records, Sept and Apr) and irregularly S to Sinaloa and NE Nuevo León. Timing of movements variable, typically migration begins late Jul or Aug and may continue to Nov, first birds penetrating S of breeding range from late Sept; major invasions sometimes start earlier, with large numbers on E seaboard and S edges of breeding range from mid-Aug or even Jul, and in big “flights” impressive passages of several hundreds moving S in a few hours (e.g. at sites on Gaspé Peninsula, in Quebec, number can exceed 1000 birds per day); recorded in S states late Oct to mid-Apr/early May (from late Sept, exceptionally late Aug, in invasion years). Return passage N in spring occurs Mar–May, and always less impressive than movement in autumn. Vagrants recorded on Socorro I, off W Mexico (Mar 1957), Bermuda (three recent records in 1970s, in Oct and Mar), Iceland (May 1970) and England (Oct 1989 to May 1990).

Status and Conservation. Not globally threatened. Generally fairly common to abundant; less common in extreme NW and extreme NE of range, and locally rare in Alaska. S boundary of breeding range variable, with isolated nesting records in many localities away from main range, and greater numbers breeding at S limit in years following good cone crops in these areas; thus, irregular in summer NW Indiana, S New Jersey, Connecticut and Rhode Island, and extremely rare breeder Iowa, Kansas, Missouri, Illinois, Maryland, C & NC Oklahoma and Texas (Guadalupe Mts); recorded also WC & SE Kentucky. Formerly bred on Guadalupe I, off N Baja California (Mexico), but last recorded there in 1971 and considered now extinct. Highest densities from British Columbia S to California, Idaho, Montana and Wyoming, in SC Canada (Manitoba, Ontario), and in New Hampshire, Maine and Nova Scotia; lower densities in Alaska (where uncommon to rare), Yukon and Newfoundland; breeding densities variable, e.g. 0.3–0.7 pairs/ha in SE British Columbia, 0–15 pairs/ha in NW Washington and 0–3 pairs/ha in N California. Spread S & E during 20th century, especially in E of range, following colonization of mature spruce and fir plantations and ornamental conifers; throughout breeding range populations increased significantly (average 2.8% per year) from 1966 to 1996. Winter abundance highly variable, but areas that constantly hold high numbers are dense forests of SE British Columbia and NE Washington, around the Michigan–Wisconsin border, and in NE USA. Historically, destruction of habitat and degradation of many remaining forests by unfavourable management practices, especially removal of dead and diseased trees and replacement of mature mixed conifer forests with homogeneous even-aged stands, presumed to have caused significant decrease in population sizes.

Bibliography. Aley & Aley (1995), Anon. (1998b), Bent (1948), Bock & Lephthien (1972), Cramp & Perrins (1993), Gaines (1988), Ghalambor & Martin (1999), Godfrey (1986), Harrop & Quinn (1996), Kilham (1973), Löhri (1961), Matthysen (1998), Matthysen *et al.* (1992), Pasquet (1988), Phillips (1986), Robinson *et al.* (2005), Root (1988), Ruiz-Campos & Quintana-Barrios (1991), Templeton & Greene (2007).

17. White-cheeked Nuthatch

Sitta leucopsis

French: Sittelle à joues blanches **German:** Weißwangenkleiber **Spanish:** Trepador Cariblanco

Taxonomy. *Sitta leucopsis* Gould, 1850, interior NW Himalayas.

Forms a superspecies with *S. przewalskii*; until recently considered conspecific, but separated on basis of significant morphological and vocal differences. Sometimes thought to be closely related to *S. carolinensis* and has been treated by some authors as conspecific with it, the contact calls of the two being rather similar; has also been allied with the “*S. canadensis* group” and, again, some similarity with latter in vocalizations. Given the close similarity of all the medium-small nuthatches, however, precise relationships obscure, and comprehensive genetic studies required. Monotypic.

Distribution. NE Afghanistan (Nuristan S to N slopes of Safed Koh and Paktia province), and Himalayas from N Pakistan (S to Kurram valley and Murree Hills) E to Kashmir and N India (N Himachal Pradesh, N Uttaranchal Pradesh E to Kumaon), and NW Nepal (Langu valley, L Rara and Dolpo E to Tarakot, on Dhaulagiri massif).

Descriptive notes. 13 cm; 13.5–15.9 g. A medium-sized, relatively long-billed nuthatch with distinctive combination of black cap and whitish side of head, lacking black eyestripe. Male in fresh plumage (Aug–Mar) has crown, nape and side of mantle glossy black, upperparts, including tertials and upperwing-coverts, medium to dark grey-blue, median and greater coverts with dark grey centres; primary coverts and alula dark grey, flight-feathers dark grey-brown, inner primaries and secondaries fringed grey-blue, P3–P5 fringed grey-blue inward of emargination and very narrowly whitish distally of emargination; central tail

feathers grey-blue as upperparts, other rectrices blackish-grey, tipped medium grey, tips progressively broader towards outer feathers, T5 with small subterminal white spot on inner web, T6 with oblique white bar subterminally on inner web and narrow white fringe centrally on outer web; lores, supercilium, ear-coverts and throat white, faintly tinged buff, breast, upper flanks, belly and centre of vent white, washed creamy buff, rear flanks and side of vent rufous, undertail-coverts slightly paler and more orange, thighs greyish-rufous; axillaries pale grey, underwing-coverts sooty black, longest under primary coverts and base of primaries white; in worn plumage, cap slightly less glossy, upperparts duller and greyer, underparts dirty creamy with grey wash (paler and less buffy); iris hazel-brown to dark brown; bill blackish, base of lower mandible pale grey; legs yellowish-brown, greenish-brown or dark brown. Female is very like male, but cap somewhat less glossy and extending a little less far on to mantle. Juvenile resembles adult, but cap duller, less clear-cut at rear, flight-feathers with slightly paler fringes and tips, cheek patch more creamy buff, and cheeks and underparts faintly vermiculated darker. **VOICE.** Call, constantly during foraging (but can be very quiet during latter stages of breeding), a distinctive, insistent, nasal or bleating “knair” or “nyah”, like sound made by tin trumpet, similar to call of *S. carolinensis* and even more so that of *S. canadensis*, given singly or in irregular series; also similarly nasal notes as rapid couplet, “que-que”, sometimes repeated for long periods, “que-que, que-que, que, que-que...”, or “quair-quair” (again recalling *S. carolinensis*).

Habitat. Coniferous forest, especially fir (*Abies*) and pine (*Pinus*), occasionally mixed forest; in Pakistan found in inner, colder mountain valleys in dry coniferous zone and also in moist temperate forest with richer mixture of broadleaf and coniferous trees. Altitudinal range generally extends to near tree-line. In E Afghanistan recorded from 2135 m in Safed Koh to 3000–3200 m in Nuristan, in latter to upper limit of coniferous forest although not up into juniper (*Juniperus*) zone; in Pakistan and NW India in summer c. 2100–3000 m, even as high as 3660 m in Chitral, optimum zone 2440–3000 m, descending in winter locally to 1800 m; in W Nepal recorded at 2745–3900 m (reports of this species to 4575 m, well above tree-line, considered improbable).

Food and Feeding. Few details of diet; insects, and conifer seeds (of various species). Usually in pairs in spring and summer; at other times may join mixed-species foraging flocks. Forages both in upper canopy of tall trees, on trunk or small branches, and on underside of thick, lichen-draped branches in lower part of cedar (*Cedrus*) trees; less frequently lower down on main trunk. Observed in summer to catch prey by flycatching.

Breeding. Season late Apr to mid-Jun; single-brooded. In apparent territorial display, male perches on top of tall fir, jerking body from side to side and flicking wings, calling all the while. Nest variable, simply a pad of grass and dead leaves, or a more elaborate construction of moss with fur and hair lining, placed 5–30 m (usually above 9 m) above ground in hole or crevice in conifer, often a crack in trunk of lightning-struck tree; abandoned woodpecker (Picidae) excavation sometimes used, and has been recorded as using a hole in ground below a root; observed to perform “bill-wiping” around nest-site (as *S. carolinensis*), but does not use mud or resin to reduce size of entrance hole. Clutch 4–8 eggs, usually 6–8, pinkish-white, with numerous reddish and purple-grey spots concentrated at one end, mean size 18.1 × 13.8 mm; incubation by female, young fed by both sexes; no information on duration of incubation and nesting periods.

Movements. Resident. May undertake some altitudinal movements, although recorded as high as 2400 m in Pakistan in winter, and perhaps not unduly inconvenienced even by deep-lying snow.

Status and Conservation. Not assessed. Usually treated as conspecific with *S. przewalskii*. Unlikely to be at any immediate risk. Common to fairly common in most of range; rather scarce in Nuristan, in NE Afghanistan.

Bibliography. Ali & Ripley (1983), Dickinson (2006), Dickinson *et al.* (2006b), Fleming *et al.* (1984), Harrap & Quinn (1996), Inskipp & Inskipp (1991), Jamdar (1987), Martens & Eck (1995), Matthysen (1998), Raja *et al.* (1999), Rasmussen & Anderton (2005b), Roberts (1992), Wunderlich (1988b).

18. Przewalski’s Nuthatch

Sitta przewalskii

French: Sittelle de Przewalski **German:** Przewalskikleiber **Spanish:** Trepador de Przewalski

Taxonomy. *Sitta przewalskii* Berezowski and Bianchi, 1891, Mindzheuskago Okrug [= Mindscheu District, presumably Minhé Huizu, in Haidong Prefecture], upper Huang He (Yellow River), east Qinghai, China.

Forms a superspecies with *S. leucopsis*; until recently treated as conspecific, but separated on basis of significant morphological and vocal differences. Monotypic.

Distribution. C China in E & S Qinghai (Daban Shan S to Amdo Plateau and upper R Hwang He, and Nanggen area), extreme SW Gansu (region SW of Xiahe and Minxian), N, C & W Sichuan (Songpan region, Qionglai Shan and around Litang) and extreme NE Xizang (NE of Qamdo); also, separately, in SE Xizang (Kongbo, in Tsangpo valley) and C Yunnan (Kunming).

Descriptive notes. 12.5 cm. A medium-small nuthatch with rich cinnamon underparts. In fresh plumage, crown, nape, side of upper mantle and rear side of neck are glossy black, upperparts, including tertials and upperwing-coverts, medium to dark grey-blue, median and greater coverts centred dark grey; primary coverts, alula and flight-feathers dark grey, inner primaries and secondaries fringed grey-blue, primaries P3–P5 fringed grey-blue inward of emargination; central tail feathers grey-blue (as upperparts), other rectrices blackish-grey, tipped medium grey, tips progressively broader towards outer feathers, T5 with small subterminal white spot on inner web, T6 with oblique white bar subterminally; lores, supercilium, ear-coverts and throat white, washed orange-buff, underparts rich cinnamon, side of breast darker cinnamon-orange, rear flanks rufous, undertail-coverts orange-rufous; in worn plumage, underparts paler and more patchy in colour; iris blackish; bill dark blue-grey, tip blackish; legs blue-grey. Sexes similar. Juvenile is much as adult but duller, especially on cap and underparts, with shorter, yellow-based bill. **VOICE.** Calls include a muffled, mellow “chip” repeated in irregular series, somewhat reminiscent of a crossbill (*Loxia*); a loud, emphatic, whistled “dweep” (or “wheel”, like that of *S. europaea*), sometimes uttered as a couplet, “dweep-cep”; a slightly nasal, querulous “que”, usually repeated 3–5 times, similar to vocalizations of *S. leucopsis*, but with far less nasal quality; and thinner “pee-pee-pee-pee...” or “seet-seet-seet-seet...” notes on same pitch but slowing towards end of phrase. Loud, clear “ti-tü ti-tü ti-tü...” notes on same pitch but slowing towards end of phrase. Loud, clear “ti-tü ti-tü ti-tü...” notes on same pitch but slowing towards end of phrase.

Habitat. Recorded in spruce (*Picea*) and fir (*Abies*) forest, also more open parkland; individual at Dzeng, in SE Xizang, in Apr was in a willow tree (*Salix*) far from any coniferous forest (possibly migrant or wanderer). Altitudinal range generally extends to near tree-line: recorded at 4270 m in Sichuan in Aug and c. 2250 m in Jun, in Xizang at 3500–4000 m in NE and 2895–3050 m in SE, and in Qinghai at 2590–2895 m.

Food and Feeding. No information.

Breeding. Seen at nest in Qinghai on 2nd Jul. No other information.

Movements. Resident; may undertake some altitudinal movements.

Status and Conservation. Not assessed. Usually treated as conspecific with *S. leucopsis*. Rare; presence confirmed at relatively few sites. Probably merits conservation status of Data-deficient or even Near-threatened; apparent rarity, however, may indicate that its categorization as Vulnerable is appropriate. Occurs in Jiuzhaigou Panda Reserve, in Songpan region of N Sichuan. Isolated records in SE Xizang, at Tse (in Dec) and at Dzeng (in Apr), both localities near Qabnag, at confluence of R Tsangpo and R Nyang Qu, might possibly refer to non-breeding visitors, the individual at Dzeng being in atypical habitat; both birds, however, had underparts much paler than those of typical members of this species, possibly indicating some introgression with *S. leucopsis* and thus making local origin plausible. Status in C Yunnan unknown; discovered at Kunming in Dec 1986, when parties of three and four individuals were recorded, but may perhaps be only a non-breeding visitor.

Bibliography. Deditius (1897), Dickinson (2006), Dickinson *et al.* (2006b), Dresser & Morgan (1899), Harrap & Quinn (1996), Ludlow (1951), Matthysen (1998), Rasmussen & Anderton (2005b), Schäfer (1938), Stott (1993), Wunderlich (1988b).

19. White-breasted Nuthatch

Sitta carolinensis

French: Sittelle à poitrine blanche **German:** Carolinakleiber **Spanish:** Trepador Pechiblanco
Other common names: White-breasted Black-capped/White-breasted American/Carolina/Common Nuthatch; Florida Nuthatch (*carolinensis*); Rocky Mountain Nuthatch (*nelsoni*); Inyo Nuthatch (*tenuissima*)

Taxonomy. *Sitta carolinensis* Latham, 1790, in America, Jamaica = South Carolina, USA.

Relationships uncertain. Bears a superficial resemblance to *S. leucopsis* and *S. przewalskii* and sometimes placed in the superspecies formed by those two, although some authors doubt such a close relationship. Recent studies of mitochondrial DNA, while not addressing this problem, suggest that present species is close to *S. himalayensis* and *S. europaea*. Geographical variation relatively slight and largely clinal, upperparts (and, to lesser extent, underparts) on average darkest in Rocky Mts and Mexico, becoming paler towards W and especially E coasts; race *alexandreae* sometimes merged with *tenuissima*, and *oberholseri* with *nelsoni*; population in NE of range (E Canada and NE USA) sometimes separated as race *cookei*, with slightly paler back, and with most females pale-capped, but differences from nominate clinal and/or not constant. Proposed race *atkinsi* from SE USA (Tarpon Springs, in Florida) synonymized with nominate, and N Mexican *umbrosa* (from Sierra Madre near Guadalupe y Calvo, in SW Chihuahua) with *mexicana*. Nine subspecies recognized.

Subspecies and Distribution.

S. c. tenuissima Grinnell, 1918 – SW Canada (S British Columbia S from Lillooet), and W USA in Cascades of E Washington and Oregon, W Montana, W Wyoming, Idaho, C & W Nevada, and E California (generally E of Sierra Nevada, S to Inyo County).

S. c. aculeata Cassin, 1856 – W Washington, W Oregon and W California (Pacific lowlands W of Cascades, and crest of Sierra Nevada and mountains in S), and extreme NW Mexico (Sierra de Juárez, in extreme N Baja California).

On following pages: 20. Western Rock Nuthatch (*Sitta neumayer*); 21. Eastern Rock Nuthatch (*Sitta tephronota*); 22. Velvet-fronted Nuthatch (*Sitta frontalis*); 23. Yellow-billed Nuthatch (*Sitta solangiae*); 24. Sulphur-billed Nuthatch (*Sitta oenochlamys*); 25. Blue Nuthatch (*Sitta azurea*); 26. Giant Nuthatch (*Sitta magna*); 27. Beautiful Nuthatch (*Sitta formosa*).

S. c. alexandrae Grinnell, 1926 – N Baja California Norte (Sierra San Pedro Mártir).
S. c. lagunae Brewster, 1891 – extreme S Baja California (Sierra de San Lázaro).
S. c. nelsoni Mearns, 1902 – Rocky Mts from N Montana S to E Nevada, Utah, Wyoming, W Colorado, Arizona (except SW deserts), W New Mexico, extreme W Oklahoma and W Texas (Davis and Guadalupe mountains), and N Mexico (NE Sonora and extreme NW Chihuahua).
S. c. carolinensis Latham, 1790 – C & E Canada from C & S Alberta (S from Lesser Slave L), SE Saskatchewan (S & E from Prince Albert), S Manitoba (S from R Swan and Winnipeg) and extreme SW & SE Ontario E to New Brunswick and Nova Scotia (including Prince Edward I and Cape Breton I), and S in USA to Gulf Coast and C Florida (E from North Dakota, South Dakota, Nebraska, Kansas, Oklahoma and E Texas).
S. c. oberholseri H. W. Brandt, 1938 – SW Texas (Chisos Mts) and NE Mexico (N Sierra Madre Oriental S to W Nuevo León and, probably, interior SW Tamaulipas).
S. c. mexicana Nelson & Palmer, 1894 – W, C & S Mexico in Sierra Madre Occidental and associated ranges from SE Sonora and C Chihuahua S to Jalisco Michoacán, Hidalgo, Puebla, and WC Veracruz (Jalapa, Mt Citlaltépetl), and S Sierra Madre Oriental from C Nuevo León (Gulf slope) and SE Coahuila S to SW Tamaulipas and E San Luis Potosí.
S. c. kinneari van Rossem, 1939 – S Mexico in Guerrero and Oaxaca (Sierra Madre del Sur).

Descriptive notes. 15.5 cm; 19.6–22.9 g. A medium-large nuthatch with white face and underparts, and straight or slightly upturned long bill. Male nominate race in fresh plumage (about Aug–Mar) has crown, nape and upper mantle black, faintly glossed greenish-blue, the black narrowing at side of upper mantle, remainder of upperparts light grey, tinged blue; upperside-coverts blackish-grey, fringed and tipped light grey, greater coverts variably tipped whiter (especially on inner feathers), alula blackish, fringed white, primary coverts blackish, narrowly fringed pale grey; inner web of inner two tertials blackish, outer webs and

streak along shaft of inner web of central tertial pale grey, inner web of outermost tertial pale grey, fringed blackish on distal half (more broadly so at tip), outer web blackish, fringed and very broadly tipped pale grey; secondaries blackish-grey, fringed and narrowly tipped pale grey, primaries sooty black, inner primaries narrowly fringed grey-white and with broader pale grey tip. P3–P6 with broad white fringe around emargination and pale grey tip; central tail feathers light bluish-grey (as upperparts), other rectrices black, T2 and T3 narrowly tipped light grey and with small whitish spot at tip of shaft, outer three feather pairs with broad white subterminal diagonal band (extending to base of outer web on T6, to tip of inner web on T4); lores, supercilium, side of head and underparts whitish (sometimes very faint dark barring on side of neck), often with very thin postocular black stripe, lower breast and belly faintly tinged buff, vent warmer buff, rear flanks pale grey, undertail-coverts pale grey with broad white triangular tips and broadly fringed orange-rufous at base, thighs pale grey with orange-rufous tips; axillaries whitish, underwing-coverts sooty black, longer under primary coverts and base of primaries white; in worn plumage, underparts slightly duller; iris dark brown; bill grey-black or black, basal two-thirds of lower mandible paler and greyer, cutting edges off-white; legs dark brown or dark grey-brown, claws blackish. Female differs slightly from male, in fresh plumage has duller cap varying from dull black to light grey (on average, palest in NE USA, and with many intermediates, some not reliably distinguishable from male in field), narrower blackish band on border of upper mantle, paler and duller grey upperparts (variably tinged brown), brownish or greenish wash on fringes of wing feathers, duller face and underparts variably washed buff. Juvenile is similar to adult but a little paler and duller, male has cap dull black (resembling that of many adult females in coloration), secondary fringes washed orange-buff, underparts washed buff (coloration close to that of worn adult), juvenile female separated from young male by duller cap and more extensive drab wash on wing-feather fringes. Races vary mainly in plumage tone (darkness or lightness), also in size and bill size: *nelsoni* male has cap with more distinct and greener gloss, darker (dark grey) upperparts with more distinct blue tone, reduced contrast in wing (darker feather centres duller and slightly browner, fringes darker grey), tertials finely fringed rufous, central tertial with more black at base of outer web, longest with more black at base of inner web, underparts cleaner and whiter, flanks and belly more extensively light grey, vent tinged buff, female cap often nearly as dark as that of male (but not so clean and glossy, and contrasting less with mantle), has variable rufous-brown tone on mantle, perhaps slightly less buff on underparts than nominate female; *tenuissima* is poorly differentiated, as previous but upperparts fractionally paler (still significantly darker than nominate), also smaller, but bill rather more slender and sharply pointed; *aculeata* is as last, but on average slightly paler above (but distinctly darker than nominate), upperparts of female slightly more olive-brown, male on average slightly buffier, less grey-toned, below (female slightly buffier), vent darker and more cinnamon-brown, also smaller and with bill shorter, weak and more slender; *alexandrae* resembles last, but upperparts marginally darker, also larger, with bill longest of all races; *lagunae* is as preceding race, but upperparts slightly darker, male underparts darker and with increased buff wash, upper flanks medium grey, rear flanks more cinnamon-rufous, is also smaller, with bill relatively stout (but more slender than that of other Mexican races); *oberholseri* is poorly differentiated, resembles *nelsoni* but upperparts (especially of female) slightly darker, underparts slightly darker and greyer (rear flanks and vent of female especially so); *mexicana* is as previous, but upperparts marginally duller, female with more intense olive-brown wash and with fringes of greater coverts and flight-feathers variably (usually strongly) tinged rusty-buff, underparts rather duller and suffused buff (less grey), male flanks darker and duller grey, female with drab pinkish extending to belly, also bill shorter and relatively stout; *kinneari* is smallest race, resembles last, but female underparts on average slightly more orange-buff, this colour extending to breast and throat, bill short and stout. **VOICE.** Contact call, given all year but especially in autumn and winter, a soft, thin, relatively high-pitched and slightly squeaky “nit” or “hit”, varying in tone and emphasis, sometimes repeated at rate of 30 per minute, or combined/alternated with louder and more emphatic “chuck” or “tuk” as conversational “hit-tuk, hit-tuk”; also single “tchup” in mild excitement. Perhaps most characteristic call a rather nasal “kri”, often rendered as “kun”, “ka-un” or “quank”, variations indicating level of excitement, e.g. single shrill and rather nasal “kri” or “qui” (“quank”) in mild excitement, irregular shrill “kri, kri, kri...” or “qui-qui-qui...” series in heightened excitement, and a repetition of two “kri” calls in quick succession, “kri-kri, kri-kri”, in even greater agitation; significant agitation or excitement indicated also by rapid series of 4–8 (4–21) “kri”-type notes (up to 8–10 per second), at varying pitches, on average higher-pitched and often in rapid series in Great Basin and Rocky Mts (race *tenuissima*); alternatively, may emit slower and quieter series of conversational, nasal “krit, krit, krit-krit, krit...”; notes; all of these “kri” (or “quank”) calls sometimes given in rather harsher and even more nasal form (notes characterized by rapid frequency modulation), in couplets or long series at varying speed, from strident “krrr-krrr, krrr-krrr” couplets to “krr-krr-krr” triplets and to longer series, also chattering “krrr-krr-krrr-krrr” phrases. Other calls include loud, harsh, trilling “br-aa” during ag-

gressive encounters, long, high-pitched quiet “phee-oo” whistle (rising and then falling) by male during display-flight and by female when soliciting copulation, and high “chrr” or “k’duck, k’duck” notes by female during courtship feeding (also by begging nestlings). Song, Jan–May in NE USA, by male from top of tall tree, most regularly shortly after dawn, in two forms: “slow” song a rapid series of 6–11 nasal and quite high-pitched “que” or “hah” notes (similar to “quank” note but higher, thinner and less nasal), c. 6 per second, “qui-qui-qui-qui-qui”, each note slightly inflected, series often starting relatively quietly but quickly building in volume (variants include phrases of more clearly upward-inflected notes, “tui-tui-tui-tui-tui”); “fast” song given in heightened excitement, c. 10–12 notes per second, rather similar to the more rapid series of “kri” notes but on average faster.

Habitat. In E parts of range, primarily mature open deciduous forest, also mixed forest, e.g. maple–hemlock–pine (*Acer–Tsuga–Pinus*) in N, also orchards, woodlots, shade trees, parks, gardens and cemeteries in suburban areas, but generally absent from spruce–fir (*Picea–Abies*) forests (e.g. the Adirondacks, in New York) and from boreal forests of N; absent also from bottomlands in Arkansas, but in SE USA does breed in pine and oak–pine (*Quercus–Pinus*) forests; penetrates Great Plains in riparian woodland and scattered stands of ponderosa pine (*Pinus ponderosa*). In W of range, open montane pine forest, also Douglas fir (*Pseudotsuga*) in W Washington, and in pinyon–juniper (*Pinus–Juniperus*), aspen (*Populus*) and, in Pacific lowlands, pine–oak and evergreen oak. In Mexico, found in montane pine–oak, and in N Baja California also pine forests. Throughout range an essential requirement is mature or rotten trees with holes suitable for nesting, and in E the presence of oak, beech (*Fagus*) and hickory (*Carya*) and their fruits may be important; favours clearings and other edge habitats. Generally lowlands in E, but to 1675 m in Tennessee; in W largely montane, and occurs at up to 2590 m in Idaho, 3200 m in Nevada, 2600 m in Arizona, at 2135–2440 m in New Mexico (dispersing to both higher and lower elevations, 3050 m and 1525 m, and also in riparian woodlands in Santa Cruz valley), up to 2590 m in SW Texas (Davis Mts), and in California breeding to 3230 m (dispersing as high as 3350 m in late summer) and in Yosemite National Park (E California) common below 915 m (probably race *aculeata*), scarce at 915–2440 m but more numerous again above 2440 m (probably *tenuissima*), and often remains in winter up to at least 2600 m. In Mexico, recorded at 1830–2600 m N Baja California (Sierra San Pedro Mártir), 1585–1950 m in Sinaloa, 1525–3050 m in Chihuahua, 1980–2440 m in N Coahuila (Sierra del Carmen), at 2440 m in Durango, 915 m in Nayarit and 3350 m in México, and from 1890 m to at least 2745 m in Oaxaca.

Food and Feeding. Food in summer largely insects and spiders (Araneae), and young may be fed entirely with animal items; in autumn and winter largely vegetarian, with diet of nuts, seeds and berries; visits garden feeders for suet, and occasionally feeds on tree sap. Males always dominant over females at food. Not very gregarious, and usually found singly or in pairs; in late summer (and sometimes through winter) also in family parties, and will join mixed-species flocks as these pass through territory. Forages on trunk and larger branches of trees, also among thinner outer twigs, in shrubs and occasionally in leaf litter on ground. Gleans from bark, and has been recorded as using a bark flake to pry off other pieces of bark; searches litter for fallen mast; sometimes takes aerial insects by flycatching. Stores large quantities of food, dispersing single items throughout territory in such places as bark crevices in trunks and larger branches of trees (occasionally covers these with bark flakes or lichen), also around habitations in cracks in poles, under loose shingles and similar sites; in spring stores food both inside and immediately outside nest-hole, and may cache such items as sugar maple (*Acer saccharum*) buds and soil pellets (which are not eaten). Removes some items from feeders and caches these nearby.

Breeding. Season usually rather early, e.g. from late Apr in Canada (Ontario), and in USA mid-Apr to May in N & E (North Dakota, New York and Ohio), late Mar to Jun in W (California) and, in S, late Feb to Mar in Oklahoma and late Mar to Apr in Texas; Mar in S Mexico (Oaxaca); single-brooded. Apparently pairs for life, and pair-bond maintained from year to year, being renewed in late winter, but partners may not be together all the time (male more wide-ranging, especially in winter, contact maintained vocally). Singing male stretches vertically upwards and bows with each note (also occasionally sings in flight). Nest built by female, materials supplied by male, a foundation of wood chips, bark strips, small pellets of earth and mud, twigs, grass, leaves and fur (used as necessary to fill cavity), lined with fur, hair, wool and feathers, placed usually in natural hole 0.5–21 m (mostly 3–12 m) above ground in dead deciduous tree or decaying stump, often rotted-out knothole, less frequently abandoned woodpecker (Picidae) excavation, nestbox or even space under eave of house used, hole with entrance 30–40 mm in diameter preferred and may enlarge entrance of existing cavity; site selected by female, which may even usurp a male from his roost-hole in early spring and take over this cavity for nesting. Clutch 3–10 eggs (usually 5–9), white, sometimes tinged pink, spotted reddish-brown, spots often concentrated at larger end with some laven-der markings, mean size 19.3 × 14.5 mm; replacement clutch laid if original lost; incubation by female, fed on and off nest by male, period 12–15 days; nestlings fed by both parents, largely by male in first few days after hatching, female spending much time in brooding young; chicks fledge after 18–26 days, continue to be fed by adults for a further 14 days. Female, usually while holding insects (sometimes fur or plant material, or nothing) in bill, engages in bill-sweeping display both in and outside nest-hole, especially around protuberances and branch junctions, possibly as a means of repelling predators or nest-hole competitors.

Movements. Generally sedentary; some retreat from extreme N parts of range and from high altitudes (notably in W) in winter, some individuals returning to same wintering territory in successive years, also some irregular and localized dispersal in spring and autumn. Movements usually over short distance, but found away from breeding areas in Great Plains and in deserts of SW, in riverine forests, on isolated wooded desert massifs, and in suburban parks and gardens; frequent in lower Sonoran zone of Arizona, but scarce or rather rare Aug–Apr visitor in areas outside breeding range in Florida, Texas (not S) and California. Commoner in some years than in others away from breeding areas, but no indication of any irregular large-scale irruptions. Vagrant in Canada to Vancouver I (British Columbia) and Sable I (Nova Scotia), in SW USA on Californian islands, and also in W Atlantic (Bermuda); in Oct 1963, one came aboard an ocean liner sailing W (6 hours out of New York).

Status and Conservation. Not globally threatened. Fairly common in much of range; uncommon to rare on edges of range. Commonest in NE USA and in some areas along R Mississippi; relatively uncommon in much of Canada and Mid West, and scarce or rare on extreme N perimeter of range and local in much of Great Plains, Great Basin and S. Recorded breeding densities vary from 4.9 pairs/10 ha (West Virginia) to 0.2 pairs/10 ha (Colorado). In Mexico, common in SW Jalisco (Volcanes de Colima) and N Coahuila (Sierra del Carmen), and fairly common in Baja California; uncommon in Sonora and Oaxaca. Thought to have decreased in early 20th century throughout SE USA, from Texas E to Florida (and currently considered close to extinction in peninsular Florida). Conversely, may be extending range in N Great Plains and into SE Washington, and recent increase in Alberta (Canada); in NE USA distribution has expanded since early 1900s along with regrowth of forests.

Bibliography. 20. Western Rock Nuthatch

Sitta neumayer

French: Sittelle de Neumayer **German:** Felsenkleiber **Spanish:** Trepador Rupestre Occidental
Other common names: (Lesser) Rock/Neumayer's Nuthatch; Syrian Rock Nuthatch (*syriaca*)

Taxonomy. *Sitta neumayer* Michahelles, 1830, Ragusa (= Dubrovnik), Dalmatia, Croatia. Closely related to *S. tephronota*, the two together often considered an offshoot of “*S. europaea* group”, the harsh aggressive call and nest details suggesting particularly close relationship with *S. cashmirensis*. They probably became fully ecologically isolated from each other when geographically separated, present species adapting to a Mediterranean climate and *S. tephronota* to more continental conditions (with colder winters and hotter summers) that favoured a larger body and bill. When coming into contact again, in S Iran, a process of what is termed “character displacement” selected for a bolder eyestripe and even larger body size in *S. tephronota*; overlap zone in N Iran may be more recent, and the two species may not have diverged sufficiently to permit altitudinal coexistence. Race *syriaca* intergrades with *zarudnyi* in CS Turkey (Taurus Mts) and with *rupicola* in E Turkey and Georgia; *rupicola* probably intergrades with *tschitscherini* in NW Iran (approximately from Mahabad S to Kermanshah). Birds of this species on Lesbos (E Greece) of uncertain racial identity, provisionally included in *zarudnyi*; others of this species in N & NE Turkey (E from Istanbul and N of Aras valley) and NC & NE Iran (E of Elburz Mts, and S of that range to Qom and Kavir) similarly of uncertain racial affiliation, provisionally included in *rupicola*. Six subspecies recognized.

Subspecies and Distribution.

S. n. neumayer Michahelles, 1830 – SE Europe in W Croatia (SE from Crikvenica), S Bosnia, Montenegro, S Serbia, Albania, S Macedonia, S Bulgaria and Greece (including islands of Corfu, Lefkada and Zakynthos).

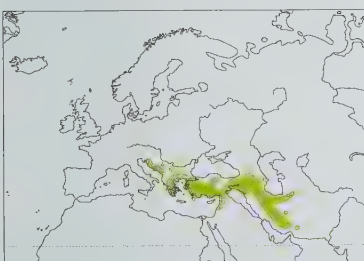

S. n. zarudnyi Buturlin, 1907 – Lesbos (E Greece) and W Turkey (W Anatolia and NW fringe of C plateau E to Elmalı and Ankara and, in S, to Taurus Mts).

S. n. syriaca Temminck, 1835 – SE Turkey E from Taurus Mts (absent S lowlands between R Firat and R Tigris), NW Syria (S to Damascus region), mountains of Lebanon and extreme N Israel (Mt Hermon).

S. n. rupicola Blanfond, 1873 – N & NE Turkey (E from Istanbul, N of Aras valley), S Georgia (S from S foothills of Great Caucasus), Armenia and SW & NE Azerbaijan (including Samaxi, in E foothills of Caucasus) S to N Iraq and NW & N Iran (E through Elburz Mts to Bojnurd, S to Kermanshah region, Qom and Kavir).

S. n. tschitscherini Zarudny, 1904 – W & WC Iran in Zagros Mts (from Kermanshah SE to Fars) and mountains S of Qom (SE to Anarak massif).

S. n. plumbea Koelz, 1950 – SC Iran (mountains of S Kerman Province).

Descriptive notes. 13–13.5 cm; 24–37.6 g. A medium-sized pale grey nuthatch with variably broad black eyestripe. Nominate race in fresh plumage (autumn–winter) has top of head and upperparts, including upperwing-coverts, light grey with faint blue tone; primary coverts and tertials medium grey with slightly paler fringes, primaries, secondaries and alula dark grey-brown, secondaries indistinctly fringed and tipped pale grey, primaries (except outer two) indistinctly fringed paler; tail as upperparts, inner webs of feathers often darker, outer four feather pairs tipped slightly paler, outer two pairs with pale buff or whitish spot at tip of

inner web; black eyestripe from nostril to side of upper mantle (c. 3 mm broad), ending irregularly; cheek, ear-coverts, side of neck and throat whitish, centre of breast and belly creamier, sides of breast and belly and rest of underparts pinkish-cinnamon; underwing-coverts and axillaries pale greyish-buff, base of underside of primaries and secondaries whitish, under primary coverts black; in worn plumage, upperparts duller and greyer, eyestripe slightly more distinct, flight-feathers bleached paler and browner, and underparts, especially flanks, paler; iris dark brown; bill dark grey or black, base of lower mandible pale bluish or bluish-flesh; legs greenish-grey to dark grey, soles sometimes slightly yellow. Differs from extremely similar *S. tephronota* in marginally darker upperparts and very slightly less prominent eyestripe. Sexes similar. Juvenile is very like adult but slightly duller, with duller eyestripe, narrow rufous tips on greater upperwing-coverts, and less contrast between breast and belly. Races vary only relatively slightly, mainly in size (nominate largest), in E of range also in prominence of eyestripe: *zarudnyi* is smaller and paler than nominate, upperparts as nominate or slightly paler, underparts paler and more extensively white, flanks and belly pinkish-buff; *syriaca* has upperparts even paler (pale ash-grey), underparts as pale or paler, size as nominate but bill slightly shorter; *rupicola* is darker above and below than preceding two, as nominate but upperparts slightly paler and less bluish, bill finer, tip laterally compressed; *tschitscherini* is small and pale, with much-reduced eyestripe 2–3 mm broad (may be virtually absent) but very narrow at rear and extending less than 10 mm behind eye (rather than 20–28 mm as in other races), upperparts slightly paler and purer grey than previous, whitish side of neck fades into grey of mantle, lower underparts paler pinkish-buff and lacking cinnamon tone; *plumbea* resembles last, but upperparts slightly darker (as *rupicola* but duller and less blue), throat, breast and belly pale grey, rather than whitish. **VOICE.** Very vocal, with wide repertoire of loud, often trilling notes. Contact call a variable “pit”, “tsik” or “chik”, may be given in flight, and at slightest excitement the notes run together to form trill or rattle, either rapidly slowing and dropping in pitch, or accelerating and then decelerating (the trills resemble the song); harsh “charr” or screeching “creea”, subdued or harsh and resembling call of Eurasian Jay (*Garrulus glandarius*), given in aggressive and sexual encounters. Song of male, from top of conspicuous rock or small tree, bird assuming very upright posture, a loud trill, typically descending in pitch, sometimes silvery, sometimes more melodic, the individual notes usually whistles of 1–2 syllables (occasionally 3), rising (“tui”, “dwi” or “dwiip”) or falling (“cheu” or “piu”), trill often preceded by descending “tititi”, thus “tititi tui-tui-tui-tui-tui...”; each male has repertoire of four or more different song types; female may sing early in season, although song much less variable; in E parts of range, at least, partners sometimes engage in antiphonal duetting in spring and autumn.

Habitat. Areas with bare rocks, typically rocky slopes, cliffs and gorges in dry or arid regions, including walls, old buildings and ancient ruins, usually on limestone; a typical species of rocky maquis. Occurs in barren regions and in areas with low shrubs, herbs and grasses, and occasionally found in woodland with scattered rocks. Generally in hilly and mountainous areas: to 800 m (locally to 1600 m) in Greece; in Turkey mostly up to 1500 m in W & C parts and 2500 m in E, but recorded to 2700 m in Taurus Mts and c. 3000 m on Nemrut and Süphan Dagı in E, and rarely to 3300 m on Karanfil Dagı (in Anatolia); in N Iran found as high as 3350 m and generally above

1525 m, but sometimes as low as 915 m; in N Israel recorded at 400–2200 m (mostly above 1000 m) and in Transcaucasus to 2000 m; in Bulgaria, recorded at up to 2200 m during post-breeding dispersal.

Food and Feeding. Food largely insects and spiders (Araneae) in summer, and nestling diet entirely animal matter; in winter mostly seeds, although snails (Gastropoda) also important. Usually singly or in pairs, and partners of established pair move around together, and sometimes defend foraging territory (disputes common at territorial boundaries), but some overlap of feeding territories can occur; in family parties after breeding and until post-juvenile moult, and sometimes larger flocks in autumn and winter (perhaps consisting mostly of immatures or individuals displaced from higher altitudes by inclement weather). Typically, forages on rocks and on ground, hopping and jumping, taking items from cracks and crevices; sometimes feeds in trees and shrubs. Wedges larger prey items in crack before smashing them with the bill; indulges in flycatching. Stores and buries food.

Breeding. Season mostly late Mar to Apr/May, at higher altitudes to late May, with presumed second clutches to early Jul; some pairs double-brooded. Both sexes defend nesting territory (i.e. immediate vicinity of nest). Nest built over course of 10–18 days, largely by male, female occasionally contributing lining material, a remarkable flask-shaped structure, sometimes rather large, with entrance tunnel (usually projecting outwards) up to 10 cm long and with internal diameter 3–3.5 cm, built of mud, animal dung, hair, feathers, beetle wings and similar, chamber lined with hair, wool, feathers, grass etc. (may fill all available space), sited on rock face, usually under slight overhang, and as low as 2 m above ground, or sometimes on building or other man-made structure; occasionally existing crevice or cavity used, entrance then sealed with mud; area around nest sometimes decorated with various objects, both natural and man-made, wedged into adjacent cracks and crevices; nests regularly reused, sometimes for many years in succession, or new nest built on to older structure. Clutch 4–10 eggs (recorded larger clutches of up to 13 eggs may include old eggs from previous years), white, usually sparsely speckled and blotched yellowish-brown to purple-brown, mean size 20.9 × 15.2 mm (nominate race); incubation by female, sometimes fed on nest by male, nest entrance may be plugged with lining material, incubation period 13–18 days; chicks fed by both parents, leave nest after 23–30 days, but probably dependent on parents for some time after fledging.

Movements. Resident; some post-breeding dispersal, sometimes to higher elevations (e.g. in Bulgaria and Israel). Also altitudinal movements in winter, when those breeding at higher elevations may descend to foothills and valleys in response to snowfall, although some remain above snow-line, on rocks and in snow-free areas. Occasional short-distance movement; in winter has occurred S of breeding range in Israel (to NW Golan and N Galilee), and two records (Apr, Oct) on Crete. **Status and Conservation.** Not globally threatened. Quite common, although local, throughout most of range; rather scarce on Kerman massif, in S Iran (race *plumbea*). European population estimated at c. 17,000–37,000 pairs in Balkans, and entire Turkish population c. 158,000 pairs. Densities variable, maximum density in Bulgaria 13 pairs/100 km². Not uncommon in mountains of Lebanon, and population on Israeli part of Mt Hermon c. 20–50 pairs.

21. Eastern Rock Nuthatch

Sitta tephronota

French: Sittelle des rochers **German:** Klippenkleiber **Spanish:** Trepador Rupestre Oriental
Other common names: Great/Greater (Rock) Nuthatch, Persian Nuthatch

Taxonomy. *Sitta tephronota* Sharpe, 1872, Kokand, Fergana, east Uzbekistan.

Closely related to *S. neumayer*, the two together often considered an offshoot of “*S. europaea* group”, nest details suggesting particularly close relationship with *S. cashmirensis*. They probably became fully ecologically isolated from each other when geographically separated, present species adapting to continental conditions (with colder winters and hotter summers) that favoured a larger body and bill and *S. neumayer* to a less extreme Mediterranean climate. When coming into contact again, in S Iran, a process of what is termed “character displacement” selected for a bolder eyestripe and larger body size in present species; overlap zone in N Iran may be more recent, and the two species may not have diverged sufficiently to permit altitudinal coexistence. Race *obscura* sometimes treated as a separate species, but intergrades with *dresseri* in Iranian Azerbaijan and with nominate in NE & SE Iran, probably also with *iranica* in E Elburz Mts (N Iran). Birds of this species in upper Aras valley (NE Turkey) and in mountains of WC & SE Iran (Qom, Anarak massif and Yazd E to Jebel Barez; also S Sistan and Baluchistan) of uncertain racial identity, provisionally placed with *obscura*; likewise, birds in Khorasan area of NE Iran provisionally included in *iranica*. Four subspecies recognized.

Subspecies and Distribution.

S. t. dresseri Zarudny & Buturlin, 1906 – SE Turkey (E from Gaziantep) E locally to Iranian Azerbaijan, S to N Iraq (Kurdistan) and W Iran (S in Zagros Mts to Fars and E to Hamadan and Esfahan).

S. t. obscura Zarudny & Loudon, 1905 – NE Turkey (upper Aras valley), S Armenia, S Azerbaijan and N, WC & S Iran (E in Elburz Mts to N Khorasan; also mountains in Qom, Anarak massif and Yazd E to Jebel Barez; also Baluchistan and Sistan).

S. t. iranica Buturlin, 1916 – S Turkmenistan and NE Iran, also C Uzbekistan (isolated mountains in C Kyzylkum desert).

S. t. tephronota Sharpe, 1872 – extreme E Turkmenistan (Kugitangtau Mts, Karabil' plateau), S Uzbekistan and SE Kazakhstan S in mountains to NE Iran (N Khorasan), Afghanistan and W Pakistan (S Waziristan S to N Baluchistan).

Descriptive notes. 15–16 cm; 42.7–55 g (*dresseri*). A medium-large to large, relatively pale nuthatch with long, heavy bill. Nominate race in fresh plumage (Sept–Feb/Mar) has top of head and upperparts, including tertials and upperwing-coverts, medium grey, black eyestripe from nostril to side of mantle (eyestripes sometimes meet across mantle) rather narrow and barely encompassing eye; alula grey, smaller feathers fringed lighter grey on outer web, primary coverts grey, faintly washed brown, flight-feathers medium grey, darker towards tip and distally of emarginations on outer web of primaries P3–P4, inner pri-

maries washed brown on outer web; tail grey (as upperparts), feathers finely tipped pale buff, outer

two pairs with buff spot on tip of inner web, outermost with large subterminal whitish spot on outer web (tail spots sometimes forming bars); chin and throat to ear-coverts and side of neck whitish, side of neck faintly tinged buff; breast creamy white, breast side faintly washed buff, grading into pale pinkish-buff on flanks and belly, light rufous-cinnamon on thighs and undertail-coverts, longer undertail-coverts centred light grey; axillaries whitish to pale grey, underwing-coverts medium grey, under primary coverts dark sooty grey, longer under primary coverts and base of flight-feathers whitish; in worn plumage, duller and browner above, especially on mantle and scapulars, flight-feathers bleached paler and browner, underparts slightly paler; iris dark brown; bill black or dark slate, base of lower mandible pale blue-grey; legs grey or blue-grey. Differs from extremely similar *S. neumayeri* in marginally paler upperparts and very slightly more prominent eyestripe, but some individuals perhaps not safely separable by plumage details. Sexes similar. Juvenile is very like adult, but eyestripe duller and less well defined, upperpart feathers faintly tipped paler, greater coverts finely fringed buff, underparts somewhat paler, breast tinged buff. Geographical variation rather complex, races differing mainly in body size, bill size and shape and prominence of eyestripe: *dresseri* is largest and palest, with a long, heavy bill, broad black eyestripe (c. 5 mm broad and encompassing eye, the most prominent of any race) more prominent, also crown and upperparts slightly paler than nominate, tail spots more distinct, flanks and belly slightly darker, colour saturation decreasing clinally from NW to SE, birds from N Iraq on average deepest rufous on flanks and belly (also largest in size) and those from S Iran (S Zagros Mts) palest below; *obscura* is somewhat smaller than previous, with darker upperparts (so eyestripe contrasts slightly less), some variation in underpart coloration, those in N Iran (Elburz Mts) as preceding race, birds in Armenia rather paler (paler even than nominate), birds from C Iran (Qom S to Kerman) even darker and duller grey above but size and underpart coloration as previous, and birds from extreme SE Iran on average paler (close to nominate); *iranica* is smallest, the smallest individuals (in Kyurendag Mts, in SW Turkmenistan) hardly larger than *S. neumayeri*; resembles nominate in coloration but paler grey (near *dresseri*) above, eyestripe shorter, underparts paler, also bill more slender. Voice. Very vocal, with loud, often trilling calls throughout year, perhaps least frequently in autumn and winter. Contact call "pit" or "chik", often run into trill or rattle. All calls very similar to those of *S. neumayeri*, perhaps fractionally slower and deeper, but in zone of range overlap (E Turkey, S Transcaucasia, N Iraq, N & W Iran) equivalent calls of present species generally louder, deeper, mellower and more slowly repeated; excitement call "kneuw", resembling call of Eurasian Jay (*Garrulus glandarius*), apparently less frequently used, but in agitation also utters "ch-ch-ch...". Song of male, from conspicuous rock or cliff, usually near nest, or from bush or sometimes tree (uses these for posturing and singing more than does *S. neumayeri*), given from Mar through to incubation stage, a loud, typically descending trill of whistled rising or falling notes (1–2 syllables, occasionally 3), very like song of *S. neumayeri* but perhaps slightly lower in pitch; each male has at least four different song types, repeating each several times before switching to different phrase; female has more stereotyped song, given in duet with male, coming in before male has finished his phrase.

Habitat. Rocky mountain slopes and valleys, cliffs, ravines and gorges; may prefer vicinity of streams, and distribution closely correlated to a milk-vetch–wormwood–Rosaceae (*Astragalus-Artemisia-Rosaceae*) vegetation community, including almonds (*Prunus dulcis*) and pistachios (*Pistacia vera*). More arboreal than *S. neumayeri* and often found in more wooded country; in Pakistan in areas with scattered junipers (*Juniperus*) and wormwood, although not in extensive tracts of juniper forest; in Iran recorded as breeding in rocky oak (*Quercus*) woods. Areas of exposed bare rock generally required, irrespective of density of local vegetation; in S Iran, found also in dry pistachio forest on stony ground where no rocky habitat available (nests also in tree holes). Forages also in dry streambeds and on roads, and in winter in C Asia descends to forests and orchards, and often found around human settlements. In C Asia occurs at up to c. 2600 m (400–2000 m in Kazakhstan, to 2000 m in Tien Shan, 1500 m in Karatau, and 800–1000 m in Dzhungarskiy Alatau); in Turkey to at least 2100 m, in S Iran at 2000–3000 m, and in Afghanistan at 915–3300 m; in Pakistan, found at 1800–2100 m N & C Baluchistan and to 2750 m in S Baluchistan, and in Ziarat descends to plains level at c. 300 m in winter. In areas where overlaps in range with *S. neumayeri*, generally found at lower elevations than latter, and in Elburz Mts (N Iran) the two species may be segregated by altitude, present species living at 915–1525 m.

Food and Feeding. Food in summer largely insects and snails (*Gastropoda*); from autumn to early spring mainly seeds, such as those of apricot (*Prunus armeniaca*), cherry (*Prunus*) and wild almond; young fed largely with insects and other arthropods, but c. 10% also on pistachio nuts. Usually singly or in pairs, the male and female of established pair moving about together and probably remaining on territory all year; after breeding, often in family parties of 2–3 individuals, and flocks of up to 16 recorded together. Forages on rock faces, on boulders and on ground, moving with jerky hops, stance often quite upright. Picks food items from cracks and elsewhere; captures aerial insects by flycatching, and recorded as taking fruits in pistachio orchards. Wedges seeds and snails in cracks and crevices, and smashes them open with bill. From late summer onwards stores snails and seeds in cracks and crevices, sometimes covering these with small stones; similar caches may be hidden under stones, behind loose bark or pressed into ground and covered with soil. Such stores perhaps an important resource during winter months.

Breeding. Season from late Feb/mid-Mar in S Tajikistan, SE Iran and Pakistan, from late Mar/Apr in Transcaucasia and Turkmenistan, and from late Apr in Kazakhstan (late first clutches in early May in many areas); some pairs double-brooded, especially at lower altitudes. Pair formation probably in early spring; rather territorial, disputes common at boundaries. Head feathers raised in display, making black eyestripe conspicuous. Nest, built by both sexes, a flask-shaped structure at variable height (some as low as 1 m above ground), constructed usually over a crack, cavity or hole in rock face, tree (especially in Iran and, possibly, Afghanistan), riverbank or building, hole a natural one, or excavated by birds themselves, or abandoned hole of bee-eater (*Meropidae*), roller (*Coraciidae*) or woodpecker (*Picidae*), cavity entrance walled up with "plaster" (a mixture of mud, saliva, excrement, resin, feathers, hair, cloth, insect fragments, even sweet papers), leaving small hole 3.5–5 cm in diameter or short conical entrance tunnel 4.5–15 cm long (tunnel less frequent, and shorter, than at nests of *S. neumayeri*), exterior of nest, as well as adjacent cracks, sometimes decorated with feathers and bright objects, interior of tree hollow often lined with mud; exceptional record of nesting in tree fork; nest can be small (c. 30 cm diameter), or in some cases very elaborate (e.g. hollow tree with every hole plastered over, leaving conical entrance tunnel), with several incomplete nests alongside the one in use, some weighing up to 32 kg; eggs laid in mud cup, sometimes lined with grass, feathers, fibres or hair; nest may be reused for several years in succession. Clutch 4–9 eggs, generally 5–7, white, usually sparsely speckled and blotched ochre and black, rarely purple-grey, markings sometimes concentrated at larger end, mean size 21.1 × 16.1 mm; incubation by female, fed on nest by male, period 12–14 days; chicks fed by both parents, mainly by male in first week, when female spends much time in brooding young, later fed mainly by female, one adult may roost with nestlings, blocking entrance with a plug of lining material; chicks leave nest at 24–26 days, after fledging stay in family party for long period, until mid-Aug/Sept.

Movements. Resident; perhaps some post-breeding dispersal from about Aug onwards, and limited altitudinal movement. In late autumn and winter may descend to lower altitudes, although this apparently very dependent on local conditions. In C Asia, those breeding at higher altitudes or in

more N areas descend from Sept onwards, although some remain in higher-lying breeding areas, especially on S-facing slopes; those breeding at lower altitudes move only in harshest weather, when recorded down to foothills of Kopet Dag, and wanderer once recorded in Karakum Desert. Little evidence of altitudinal movement in Pakistan, and those descend to lower slopes and valleys, and even to plains level.

Status and Conservation. Not globally threatened. Generally fairly common in suitable habitat. Common in Afghanistan and Pakistan; apparently scarce in Armenia. A few data on densities, e.g. c. 1 pair/10 ha recorded; in ravines 1–2 pairs/km, although seven occupied nests recorded along 600 m of a gorge.

22. Velvet-fronted Nuthatch

Sitta frontalis

French: Sittelle veloutée **German:** Samstirnkleiber

Spanish: Trepador Piquirrojo

Other common names: Velvet-fronted Blue Nuthatch

Taxonomy. *Sitta frontalis* Swainson, 1820, Sri Lanka.

Sometimes placed with *S. solangiae* and *S. oenochlamys* in a separate genus, *Oenositta*. The three may form a superspecies and have at times been considered conspecific. Racial identity of Sumatran populations requires verification, and these have been variously ascribed to nominate, *saturator* and/or *velata*. Five subspecies recognized.

Subspecies and Distribution.

S. f. frontalis Swainson, 1820 – peninsular India, especially in hills (absent from large areas, e.g. N & NW, Gangetic Plain and Deccan plateau), Himalayan foothills from Kumaon E to NE India (S from Assam and Nagaland), Bangladesh, Sri Lanka, S China (W, S & SE Yunnan S to Xishuangbanna, C & S Guizhou, W Guangxi and W & S Guangdong), Myanmar, Thailand S to Isthmus of Kra (absent from C plains and much of NE), and Indochina.

S. f. saturator E. J. O. Hartert, 1902 – Malay Peninsula S of Isthmus of Kra (including Phuket, Penang and Singapore), Lingga Archipelago, Sumatra (including Simeulue I) and Bangka.

S. f. corallipes (Sharpe, 1888) – Borneo, including Maratua I (off E coast).

S. f. palawana E. J. O. Hartert, 1905 – Palawan and Balabac, in W Philippines.

S. f. velata Temminck, 1821 – Java.

Descriptive notes. 12.5 cm; 8.5–17 g (*frontalis*). A medium-small nuthatch with bright red bill (blackish in juvenile), yellow eye and eyering, black forehead and violet-blue upperparts. Male nominate race in fresh plumage (Jul–Jan) has lores, forecrown and narrow postocular stripe black; crown, upperparts and lesser and median upwing-coverts violet-blue, brighter and paler blue immediately adjacent to black forecrown; greater upwing-coverts blue-grey with diffuse violet-blue fringes, alula and primary coverts blackish, smaller feathers of alula and distal parts of primary coverts fringed violet-blue, tertials grey-blue (bluer on outer web), longest tertial with concealed blackish stripe along shaft, secondaries and inner primaries greyish-black, grading to grey-blue submarginally, with narrow brighter blue fringes, outer primaries blackish, P3–P4 fringed pale blue inward of emargination, P5–P7 fringed pale blue around emargination; central tail feathers grey-blue with violet-blue fringes, outer rectrices black, tipped grey-blue and on outer web fringed violet-blue (outermost fringed grey-blue), outer three feather pairs with slightly paler subterminal spot on inner web; cheek dull violet-blue, fading to lavender on ear-coverts and side of neck; chin and throat whitish, breast dull beige, flanks and belly to vent darker and drabber (although washed lavender), undertail-coverts dull beige, diffusely tipped lavender; axillaries whitish, anterior feathers tipped dull violet-blue, underwing-coverts black, longer under primary coverts and base of primaries whitish; in worn plumage duller and greyer above, and underparts slightly duller, pale grey-white with dull buff wash (less lilac); iris yellow, dull pale yellow to orange-red eyering; bill red, tip of upper mandible blackish; legs dark brown, soles orange-yellow. Easily distinguished from rather similar *S. solangiae* and *S. oenochlamys* by bill colour. Female is as male, but lacks black postocular stripe and has underparts, especially breast and belly, washed cinnamon-buff, with lilac tones reduced. Juvenile resembles adult, but bill blackish, iris brownish, upperparts slightly duller and greyer, chin and throat duller, underparts washed cinnamon-orange or orange-buff (slightly more orange-buff than adult female), undertail-coverts pale pinkish-buff with fine dark cinnamon-brown bars. Race *saturator* is darker and more lilac than nominate, with chin off-white, throat and male underparts pinkish-buff with lilac wash, female cinnamon-buff with lilac wash (slightly less pure lilac than male), legs brown; *corallipes* is similar to last but has legs and feet bright orange-red; *palawana* resembles nominate, but on average slightly darker and browner below, throat rather less extensively white, sexes rather similar in underpart coloration, male lilac-washed pinkish-buff (near female nominate), female cinnamon-orange (buffer with wear), legs and feet light brown; *velata* resembles nominate, but throat more extensively white (ear-coverts still lilac), male underparts paler and more washed out, more pinkish-buff, with reduced lilac and increased grey tones, female believed very similar to nominate.

Voice. Noisy. Common calls a single full, hard "chat", "chit", "chlit" or "chip" and a much thinner and more silbant "sip", "sit" or "tsit" (many intermediates), former often in rapid couplet as "chit-chit", or in short rattling series, "chit-chit-chit" or "chit-it-it-it..."; the two notes sometimes mixed, typical phrase "chip, chip, sit-sit-sit-sit-sit-sit-sit", and both variants given also in flight. Song a series 1.5–2 seconds in duration of "sit" notes, individual notes usually still distinguishable, and may become a fast, hard rattle.

Habitat. Wide variety of forest types, including tropical rainforest, swamp-forest, semi-evergreen, hill evergreen, mixed deciduous, dry dipterocarp; also pine (*Pinus*) and mixed pine-oak (*Pinus-Quercus*) forest, especially in Myanmar and Thailand, and in Sumatra noted in pine plantations; in Western Ghats of SW India almost exclusively in evergreen forest. Also in mixed bamboo jungle, overgrown rubber plantations and other cultivation with tall trees, shade trees in tea, coffee and cardamom plantations, mature mangroves and coastal casuarina (*Casuarina*) trees. Optimum habitat is more open evergreen types and moist-deciduous/mixed deciduous forest (known as "sal forest" in Indian Subcontinent); much lower densities in closed-canopy rainforest. Generally at low altitudes. In Indian Subcontinent from plains to c. 1500 m, occasionally to c. 2200 m (and recorded in Sikkim as high as 1980 m in winter); in Myanmar to 1830 m (in N only at 460–915 m), and in

Thailand to 1800 m (in N commonest above 830 m); in China noted at 340–680 m in Guizhou, 1170 m in SE Yunnan and 1500 m in W Yunnan (and reported at up to 1825 m); found at 180–1350 m in Vietnam and Laos, and recorded at Da Lat (in S Vietnam) at 930–1450 m; 200–400 m in Cambodia; in Malay Peninsula recorded to c. 1150 m, in Borneo to 2200 m, and in Sumatra and Java to c. 1500 m.

Food and Feeding. Food insects and spiders (Araneae). Found in pairs and in parties of up to six individuals, occasionally more, with up to 20 recorded together; often joins mixed-species foraging flocks. Very active. Forages on tree trunks, less often on small outer branches and least on main branches, generally in upper and middle storeys of tall forest trees; occasionally feeds in undergrowth and on fallen logs, but not seen to visit ground. Vigorous wing-flapping observed, apparently an attempt to flush insects from face of tree trunks.

Breeding. Season Apr–Jun in N India, Jan–May in S India and Sri Lanka, and in Myanmar Mar–Apr in N and Feb–Mar in S, May–Jun in China, Mar in N Thailand and Apr in Malay Peninsula, and Apr–Aug in W Java; nests found mid-Mar in C Annam (Vietnam) and Feb–May in Borneo. Nest, built by both sexes, a pad of moss (often mixed with feathers), lined with fur and feathers, placed 1–12 m (usually below 7 m) above ground in hole in dead branch or tree trunk, sometimes in abandoned woodpecker (Picidae) or barbet (Capitonidae) hole; selected hole usually small and is often enlarged by the birds themselves, but occasionally a large hole will be reduced or finished with “plaster” (presumably mud). Clutch 4–5 eggs in N India, 3–4 in S India and Java, 3–6 in Myanmar, one clutch of 3 recorded in Borneo, eggs white, variably (usually rather heavily) spotted and blotched brick-red and occasionally purple, mean size 17.2 × 13.2 mm; no information on precise incubation period; chicks fed by both sexes, no information on duration of fledging period.

Movements. Resident; few indications of altitudinal movement.

Status and Conservation. Not globally threatened. Generally common in Indian Subcontinent and SE Asia, and can be abundant in optimum habitat, but local in Bangladesh and scarce in N Vietnam (Tonkin). Somewhat less abundant in Malay Peninsula, Sumatra, Java, Borneo and Palawan, but still fairly common in most areas; e.g. in Borneo fairly common near coast and in submontane areas, such as on Mt Kinabalu and in Kelabit uplands, but scarce in intervening lowlands, and common in C Kalimantan. Scarce to rare in China. In China, first recorded in Hong Kong Apr 1989, since when observed with increasing regularity, especially in Tai Po Kau (breeding in 1993); initially thought to relate to individuals of captive origin, but in view of widespread occurrence may instead refer to previously undetected population.

Bibliography. 23. Yellow-billed Nuthatch

Sitta solangiae

French: Sittelle à bec jaune **German:** Gelbschnabelkleiber **Spanish:** Trepador Piquigualdo
Other common names: Lilac Nuthatch

Taxonomy. *Calositta solangiae* Delacour and Jabouille, 1930, Loquih, near Cha Pa, north-west Tonkin, Vietnam.

Sometimes placed with *S. frontalis* and *S. oenochlamys* in a separate genus, *Oenositta*. The three may form a superspecies and have at times been considered conspecific. Present species, however, occurs together with *S. frontalis* in Vietnam, overlapping in both range and altitude in NW Tonkin (Fan Si Pan Range) and S Annam (Da Lat Plateau). Relationship with *S. oenochlamys* more problematic, but Hainan race *chientfengensis* of present species may form link between the two (both are yellow-billed, whereas *S. frontalis* has red bill). Population of this species recently found on Kon Tum Plateau–Lo Xo pass area of Vietnam and adjacent SE Laos (Xe Sap region, in Xe Kong Province) of unknown race; study required. Three subspecies currently recognized.

Subspecies and Distribution.

S. s. solangiae (Delacour & Jabouille, 1930) – N Vietnam (Fan Si Pan Range, in NW Tonkin).

S. s. chientfengensis Cheng Tsohsin *et al.*, 1964 – S Hainan I, in S China.

S. s. fortior Delacour & Greenway, 1939 – Da Lat Plateau (Langbian Plateau), in S Vietnam (SC Annam).

Descriptive notes. 12.5–13.5 cm; 14–16 g (*chientfengensis*). A medium-small to medium-sized nuthatch with yellow bill, iris and eyering, black forecrown and violet-blue upperparts. Male nominate race in fresh plumage has lores, forecrown and postocular stripe velvety black, crown pale lavender-blue or lilac-blue, nape and upper mantle slightly paler greyish-mauve, some whiter feather bases visible (especially in centre of upper mantle), remainder of upperparts dull greyish-blue, longer uppertail-coverts blackish-grey with violet-blue tips; lesser and median upwing-coverts blackish-grey, broadly fringed violet-blue,

greater coverts black, broadly fringed violet-blue (dark centres concealed), alula and primary coverts black with narrow violet-blue fringes, tertials dull violet-blue (greyish-black base of inner webs concealed), secondaries and inner primaries black with violet-blue fringes, P6–P7 narrowly fringed pale blue around emargination, P3–P5 broadly fringed pale blue inward of emargination; central tail feathers dull violet-blue to grey-blue with blackish shaft streak, other rectrices black, T2–T5 fringed violet-blue on outer web (fringes broadening towards base) and tipped dull blue-grey, T6 similarly fringed and tipped dark grey (tips progressively broader from inner feathers to outer), subterminal white spot on inner web tiny on T2 and moderately well marked on T6; cheek, ear-coverts and side of neck light greyish-mauve, chin and throat off-white, underparts drab pale greyish; axillaries pale greyish-beige, underwing-coverts sooty black, base of primaries whitish; iris pale yellow, yellow eyering; bill lemon-yellow or golden-yellow, small black tip on upper mandible; legs grey. Female as male, but lacks black postocular stripe (sometimes a faint black line visible behind eye). Juvenile is very poorly known; bill of recently fledged birds on Hainan (race *chientfengensis*) reported as being dull yellow, but change from blackish bill at fledging to adult coloration may be rapid. Races differ mainly in plumage tone and in size: *fortior* is rather bigger than nominate, darker above, crown to upper mantle light greyish-mauve (tips of crown feathers washed violet-blue, whiter feather bases often contrastingly visible on nape and upper mantle), upperparts dull violet-blue, underparts pale greyish-beige with faint violet cast (especially on flanks);

chientfengensis is smaller than last, has upperparts more greyish-blue than nominate (crown and nape washed purple, mantle tinged lilac-rufous, ear-coverts and side of neck lilac-rufous), white terminal spots on tail less prominent, much paler below (chin and throat white, underparts below breast fulvous-rufous, darkening somewhat posteriorly), also bill tip more extensively dark (distal third of upper mandible blackish-brown). VOICE. Calls include “chit”, often doubled or in series, “chit-it” or “chit-it-it-it-it-it-...”, also “sit”, all very similar to calls of *S. frontalis*. Song a fast “sit-ti-ti-ti-ti-...”, 1–2.5 seconds in duration, slower and slightly lower in pitch towards end; resembles song of *S. frontalis* but perhaps faster and more “whinnying”.

Habitat. Hill evergreen forest, including relatively open, partially logged areas. In Vietnam, recorded at c. 1550–2500 m in NW Tonkin and at 1450–2100 m in S Annam (Da Lat Plateau); found at 800–1500 m on Hainan.

Food and Feeding. Food insects. Found singly or in small groups on Hainan; in Vietnam in groups of up to five individuals, in mixed-species foraging flocks.

Breeding. Adults feeding fledged young in C Annam on 5th Mar and on Hainan on 22nd Apr. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Hainan EBA and in Da Lat Plateau EBA and in Fan Si-Pan and Northern Laos Secondary Area. Not recorded for many years in NW Vietnam, but recent records suggest species not as rare there as previously thought. Probably rather common on Da Lat Plateau, in S Annam (race *fortior*), where small numbers recorded since 1990 in surveys; records from Mt Bi Doup, Mt Lang Bian, Cong Troi and near Da Lat. Status of this species on Kon Tum Plateau, straddling Vietnam–SE Laos border, uncertain; fieldwork and further study required. Main threat throughout Indochina is deforestation, e.g. much of Da Lat forest being cleared by shifting cultivation, charcoal-burning activities and fuelwood collection, and these activities are increasing in intensity following government resettlement programmes. Discovered as recently as 1963 on Hainan I (race *chientfengensis*), and not uncommon in good forest; has been recorded from Diaoluoshan, Wuzhishan, Bawangling, Jiaxi and Jiangfengling. Remaining forests on Hainan, however, under threat, and in 1981 only 2420 km² of forest (7.2% of total land area) remained, although most of surviving forest likely to be at higher altitudes and thus suitable for present species. Despite this apparently large area, forest cover declined by 72% between 1949 and 1981, and the species’ future on Hainan is far from secure.

Bibliography. Anon. (2007i), Butchart & Stattersfield (2004), Cheng Tsohsin & Tan Yaokuang (1973), Cheng Tsohsin *et al.* (1964), Collar *et al.* (2001), Delacour & Greenway (1939, 1940), Delacour & Jabouille (1930, 1931), Dickinson (2006), Dickinson *et al.* (2006b), Harrap (1991), Harrap & Quinn (1996), King & Liao Weiping (1989), Lee Kwok Shing *et al.* (2006), Pui Lok *et al.* (2005), Robson (2000b), Robson *et al.* (1993a, 1993b), Stattersfield & Capper (2000).

24. Sulphur-billed Nuthatch

Sitta oenochlamys

French: Sittelle des Philippines

Spanish: Trepador Filipino

German: Schwefelschnabelkleiber

Taxonomy. *Dendrophila oenochlamys* Sharpe, 1877, Guimaras, Philippines.

Sometimes placed with *S. frontalis* and *S. solangiae* in a separate genus, *Oenositta*. The three may form a superspecies and have at times been considered conspecific. Possibly more closely related to *S. solangiae*, Hainan race *chientfengensis* of which may form link between the two species (both are yellow-billed, whereas *S. frontalis* has red bill). Geographical variation partly clinal, colour saturation and dominance of lilac tones in plumage increasing from N to S through islands. Six subspecies recognized.

Subspecies and Distribution.

S. o. mesoleuca (Ogilvie-Grant, 1894) – NW Luzon (W Cordillera mountains), in N Philippine Is.

S. o. isarog Rand & Rabor, 1967 – Luzon (except NW).

S. o. oenochlamys (Sharpe, 1877) – WC Philippines (Panay, Guimaras, Negros and Cebu).

S. o. lilacea (J. Whitehead, 1897) – EC Philippines (Samar, Biliran and Leyte).

S. o. apo (Hachisuka, 1930) – Mindanao (except Zamboanga Peninsula), in S Philippines.

S. o. zamboanga Rand & Rabor, 1957 – W Mindanao (Zamboanga Peninsula), Basilan and East Bolod I.

Descriptive notes. 12.5 cm; 16.3–16.4 g (*isarog*). A medium-small nuthatch with yellow bill, iris and eyering, black forecrown, and violet-blue upperparts variably tinged lilac. Male nominate race in fresh plumage has forehead and forecrown velvety black, extending behind eye as narrow black eyestripe, crown violet-blue tinged mauve, nape and upper mantle vinaceous with slight lilac tinge and with pale buff feather bases extensively visible (forming pale “shawl”), lower mantle, scapulars, back and rump violet-blue, tinged grey; upwing-coverts violet-blue, inner webs of greater coverts black (mostly concealed), alula black, smaller feathers edged and tipped violet-blue, primary coverts black, outer web and tip violet-blue, tertials grey-tinged violet-blue, two longer tertials with extensive black streak along shaft and inner web (mostly concealed on folded wing), secondaries greyish-black with broad violet-blue fringes and greyer tips, primaries sooty black, inner primaries narrowly fringed lilac-blue distally, fringe broadening into duller grey-blue on outer webs and tips, outer primaries variably edged violet-blue on basal half; central tail feathers dull violet-blue with dark grey shaft streak, other rectrices blackish with violet-blue edging and broad dull violet-blue tip, tip progressively broader towards outermost feather, distal third of which dull violet-blue (blackish colour fully concealed when tail closed); anterior part of lores and cheek pale buff, grading to violet-blue on ear-coverts and pale buffish-lilac on side of neck, this colour extending to meet pale shawl on nape and upper mantle; chin and throat white, merging into pale cinnamon-orange underparts, lightly washed lilac on flanks and belly to vent; axillaries pale cinnamon-orange, underwing-coverts sooty black, base of primaries white; iris bright greenish-yellow to orange-yellow, orbital skin chrome-yellow or greenish-yellow; bill greenish-yellow; legs olive-green to brown. Female as male, but black eyestripe lacking or only faintly indicated (sooty, and most clear-cut, at rear), underparts on average slightly more orange-toned, with little of lilac wash. Juvenile resembles adult, but underparts more orange-toned, and may lack pale patch on nape/upper mantle. Races vary mainly in darkness of plumage colour: *mesoleuca* is palest, with ear-coverts violet-blue, nape and upper mantle pale pinkish-buff with lilac wash and often with very pale (even whitish) centre,

25. Blue Nuthatch

Sitta azurea

Spanish: Trepador Azur

Other common names: Azure Nuthatch

S. a. azurea Lesson, 1830 – E Java.

Food and Feeding. Food insects. Occurs in pairs or in parties of up to seven individuals, usually associated with mixed-species flocks; foraging parties restless and very vocal. Forages in middle and upper storeys of tall forest, sometimes also in smaller trees, usually on trunks and main branches. Spends much time in scanning, only occasionally making lobs at bark.

Bibliography. Dickinson (2006), Dickinson *et al.* (2006b), Harrap & Quinn (1996), Hellebrekers & Hoogerwerf (1967), Kuroda (1936), MacKinnon (1988), Medway & Wells (1976), Robinson (1928), Robson (2000b), Wells (2007).

26. Giant Nuthatch

Sitta magna

Spanish: Trepador Gigante

S. m. magna R. G. W. Ransay, 1876 – C & E Myanmar (S from Mogok hills, E from Menetaung range and Kalaw, to Mt Nattaung, in N Karen), adjacent S China (SW Yunnan) and NW Thailand

Food and Feeding. Food insects and berries. Usually found singly or in pairs, seldom in flocks (in spring), but in S China (Yunnan) recorded in autumn and winter in mixed flocks with other species of genus. Generally not so restless as the smaller nuthatches, but behaviour otherwise similar, and frequently adopts characteristic head-down pose. Forages mostly in pines, generally high up, only occasionally descending lower, on trunk and upper limbs.

Breeding. Poorly known. In Myanmar (S Shan State), a nest found in early Apr was a pad of material similar to that used by congeners, placed in natural hole c. 2 m above ground in tree trunk, entrance (barely large enough to admit adults) had been "rounded off slightly by the parent bird."

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family TICHODROMIDAE (WALLCREEPER)

- Medium-sized passerine with long, slightly decurved bill, long, broad and rounded wings, and large feet; strikingly coloured in crimson and black.
- 16.5–17 cm.

- Southern Europe and south-central and southern Asia.
- Mountains, rocky habitats, cliffs, boulder-strewn slopes and shady gorges.
- 1 genus, 1 species, 2 taxa.
- No species threatened; none extinct since 1600.

Systematics

Any species convergently similar to a European nuthatch (*Sitta*) or treecreeper (*Certhia*) has been associated with one or the other of these genera, and the scansorial species, those which forage by climbing on trees or rocks and cliffs, have often been united in one family. The Wallcreeper (*Tichodroma muraria*), formerly placed with the treecreepers in the family Certhiidae, was later included in the nuthatch family (Sittidae), there being significantly more support for the latter treatment from morphological and ethological criteria, which had been thoroughly compared and analysed in the literature. Data derived from DNA–DNA hybridization suggest that the Wallcreeper is, indeed, more closely related to the Sittidae than it is to the Certhiidae, but the discussion about its taxonomic relationships is not new, as G. A. Girtanner, of St Gallen, in Switzerland, was much preoccupied with the subject as early as the 1860s.

Morphological similarities between *Tichodroma* and *Sitta*, but in which *Certhia* differs from those two genera, include the plumage colour of the upperside, and the colour pattern and shape of the tail. The Wallcreeper and the nuthatches are blue-grey on the upperside, whereas the upperparts of the *Certhia* are brown and cryptically patterned, resembling bark, although the wing patterns of the three genera *Tichodroma*, *Sitta* and *Certhia* are distinctly different. The Wallcreeper and the nuthatches have a short, straight, square-ended tail, sometimes with small white tips or corners, whereas *Certhia* possesses an unmarked, long and graduated tail, which is used as a prop during climbing. In addition, the young of both *Tichodroma* and *Sitta* have long, grey natal down on the head, scapulars and back, while young *Certhia* species have down on the head only. In fact, it is only in the shape of its slender, slightly decurved bill that *Tichodroma* resembles the genus *Certhia* more than it does *Sitta*.

Among ethological similarities between *Tichodroma* and *Sitta*, including those evident from H. Löhrl's comparative study of certain behavioural characters of these two genera, as well as *Parus*, *Aegithalos* and *Certhia*, are the following. Regular wing-flicking is performed by Wallcreepers and nuthatches, admittedly for a different level of excitement by nuthatches, but is not performed at all by treecreepers. A characteristic pendulum movement of the head and body, which is absent from the behavioural repertoire of *Certhia*, is well documented for *Sitta*; Löhrl noted such swaying by *Tichodroma* only when a individual was leaving its nest after a feeding visit, and R. Gränitz recorded it once

when a Wallcreeper was perched and singing in winter. The habit of occasionally coming to the ground is common to the Wallcreeper and nuthatches alike, as is that of roosting in holes throughout the year; treecreepers, on the other hand, although they gather much nest material on the ground, are otherwise exclusively climbers, and they roost outside holes and crevices, in which they only nest. As mentioned later (see Breeding), the task of incubation is undertaken entirely by the female Wallcreeper, as is so also with the nuthatches, but both sexes of *Certhia* incubate; furthermore, both the incubation period and the fledging period of the first two genera are longer than those of *Certhia*. Apart from the complete adult post-breeding moult, both *Tichodroma* and *Sitta* have a variable partial moult in the spring, while *Certhia* has only the complete post-breeding moult. Further similarities between *Tichodroma* and *Sitta* relate to the threat postures and gliding display-flights during the breeding season.

Tichodroma is now generally considered to belong in a family of its own. For K. H. Voous, who noted its "extraordinary adaptations to extreme mountain conditions", the Wallcreeper was the sole species in the family Tichodromidae. It should be noted that the family name has frequently been spelt "Tichodromadidae", but there appears to be no justification whatsoever to support this spelling. The family comprises a single genus, *Tichodroma*, and just one species, *Tichodroma muraria*, which is itself often considered monotypic, as the two currently recognized subspecies, the nominate in the west of the range and *nepalensis* farther east, are poorly differentiated. Conversely, L. A. Portenko supported the separation of an additional subspecies, *longirostra*, occurring in the Caucasus area and northern and western Iran, and proposed also that the Central Asian population be regarded as representing a further race, *ognewi*. The differences of these forms from, respectively, the nominate race and *nepalensis* appear, however, to be too slight to warrant such an arrangement.

Support for the recognition of a distinct family Tichodromidae is provided by several physical features. First, the long, thin tongue of *Tichodroma* is divided (barbed) at the tip, but it lacks the bristles characteristic of *Sitta* and *Certhia*; second, the tarsus of *Tichodroma*, markedly slender for a climber, is covered anteriorly with a single long lamina, whereas the tarsi of *Sitta* and *Certhia* are distinctly scutellate. Wallcreepers also have rather long, slender toes, the front claws being sharply decurved, the conspicuously long hind claw less so. The leg of *Sitta* is short, and its foot is large and strong, with laterally compressed claws; the *Certhia* foot is short, with rather long toes and strong claws, that of the

hind toe being particularly long. *Tichodroma* differs distinctly from *Sitta* in its food-handling techniques. Unlike nuthatches, it takes only animal prey, and it deals with harder-bodied individuals by carrying them in flight to a level surface, where it dismembers them by beating them against the substrate. Nuthatches, on the other hand, wedge items in crevices or holes and hammer them to pieces with blows of the bill. Unlike some *Sitta*, the Wallcreeper does not store food. Neither nuthatches nor Wallcreepers use the foot for holding larger food items, although one female Wallcreeper did employ a comparable technique when collecting nest material (see Breeding).

In early work by C. G. Sibley, the biochemical behaviour of the Wallcreeper's egg-white proteins as revealed in electrophoretic patterns showed no resemblance to that of the Sittidae or the Certhiidae, and differed also from that of the tits (Paridae), the parrotbill genus *Panurus* (Paradoxornithidae) and the Australasian treecreeper genus *Climacteris* (Climacteridae). Data on DNA-DNA hybridization from studies by Sibley and J. E. Ahlquist indicated that the genera *Sitta*, *Tichodroma* and *Certhia* belonged to the kin group of the tits and, furthermore, supported the idea of an especially close relationship between *Tichodroma* and *Sitta* as "sister taxa", not close, but each other's closest relatives. As a consequence, these authors treated *Tichodroma* and *Sitta* as representing two monogeneric subfamilies, Tichodrominae and Sittinae, of the Sittidae within the superfamily Sylvioidea, and sharing a common ancestor with the other sylvioids some 40–45 million years ago. Some authors still prefer to regard the Wallcreeper as a monotypic subfamily of the Sittidae.

More recent molecular studies, by P. Alström and colleagues, were analysed and interpreted by A. J. Helbig in respect of the central European species. It was proposed that Sibley and Ahlquist's "parvorder Passerida" be divided into three basic groups, comprising five superfamilies and two separate families, the Regulidae and the Bombycillidae. In the first such group, the Paroidea, comprising the parid tits and allies, are linked with, and may be the sister-group of, the Sylvioidea, while the third group is the Passeroidea. It is the second group that is most relevant to the Wallcreeper; this embraces the superfamilies Certhioidea (Sittoidea) and Muscicapoidea, as well as the Regulidae and the Bombycillidae. Within the Certhioidea, there

is an apparently close relationship between the primarily Old World nuthatches, treecreepers and Wallcreeper and the almost exclusively New World gnatcatchers (Polioptilidae) and wrens (Troglodytidae). This relationship was first revealed only by molecular studies, but is now firmly corroborated through the work of Sibley and Ahlquist, F. H. Sheldon and F. B. Gill, and F. K. Barker and others.

Morphological Aspects

In build and in the coloration of its abundant, soft plumage, the Wallcreeper is perfectly adapted to its mountain environment. Living in inaccessible sites, it can be difficult to see, especially as its dusky-grey and black plumage may blend with the rocks. Those individuals which spend the non-breeding season, and in some cases even breed, at lower altitudes, including on buildings, may be easier to observe. Once the characteristic wing-flicking draws attention and, even more so, when the bird flies, typically with an erratic, flitting and skipping motion, the full elegance and beauty of its plumage, especially the black, carmine-red to pink and white of the wings, are revealed. The carmine-red colour is derived from the carotenoid pigment astaxanthin.

Of the total body length of 16.5–17 cm, the bill constitutes 2.3–4.2 cm and the tail 5.5–6.5 cm. The Wallcreeper appears about the size of a Eurasian Nuthatch (*Sitta europaea*) and thus larger than it really is, and it is therefore surprising that its body weight of 16.7–19.3 g corresponds to the average for a Great Tit (*Parus major*), which contrasts strongly with the large wings (see below). Young Wallcreepers exceed 20 g about a week before they leave the nest, but they lose the excess around the time of fledging.

Whereas the Wallcreeper's tail is short and square-ended, the wings are disproportionately large, long and rounded, reminiscent of those of a Hoopoe (*Upupa epops*) or a butterfly (Lepidoptera), and have a span of 27–32 cm. Wallcreepers are excellent short-distance fliers, but they look rather ponderous over longer distances; nevertheless, they do sometimes fly high over mountain valleys or passes when migrating or moving from one cliff face to another, and they can then give the impression of flying quite strongly. For one Slovakian observer, a Wallcreeper in "calm flight" along a rock face is reminiscent of a Spotted Nutcracker (*Nucifraga caryocatactes*) or a Eurasian Jay (*Garrulus glandarius*). F. A. Kipp devised a formula for determining the "hand-wing index" of birds, which is defined as the length of the hand, measured from the end of the outermost secondary (S1) to the wingtip, as a percentage of the total wing length. The figure for the Wallcreeper, 20–21%, does suggest that this species' wing is not well suited to active long-distance flight. Apart from the importance of the wings as a support when climbing, their unusual shape and the large wing area do, nevertheless, allow the bird to make skilful use of the updraughts characteristic of mountain regions to ascend to much higher altitudes. Flying with light wingbeats into the wind, the bird is quickly blown upwards with little effort on its own part and almost without moving the wings; not surprisingly, it may drift slightly off course, and it then corrects this by using active flapping flight to bring it back to its target. In an "investigative flight" described by M. Saniga (see Food and Feeding), the wingbeats appear exaggerated, the alternate spreading and closing of the flight-feathers causing considerable changes in the apparent size and the amount of visual flashing of the wings' bright colours. In order to descend from a great height to places at the foot of a cliff, the Wallcreeper closes its wings and holds them so tight to the body that it drops like a stone. It will then open its wings only just before landing, so that they act as a parachute and the bird can land safely after a slight upward swoop. The unusually large wings are especially well suited also to stopping this plummeting descent. A downward glide during which the wings are held up in a V-shape and the tail raised has also been reported. Saniga found that a Wallcreeper employing this gliding descent, usually when flying down to a nest with food or removing faecal sacs, resembled a falling leaf. Similarly, in Bulgaria in March, W. Baumgart observed how two individuals, separately, launched themselves from a rock face in

[*Tichodroma muraria nepalensis*, Dehra Dun, Uttarakhand, India.
Photo: Rajneesh Suvarna]

The family Tichodromidae comprises a single species, the Wallcreeper. Its closest relatives are probably the nuthatches (Sittidae), which share the Wallcreeper's scansorial habits. The Wallcreeper is morphologically adapted for ascending the cliffs and boulder-covered slopes that compose its habitat. Its strikingly long slender toes are complemented by strongly decurved front claws and a remarkably long rear claw. This foot structure enables the Wallcreeper to hop between rocky protuberances, thereby compensating for legs that are slimmer than those of fellow climbers, such as nuthatches and treecreepers (Certhiidae).

alarm when a Common Kestrel (*Falco tinnunculus*) came close, and then dropped like falling leaves for 6–7 seconds, with wings and tail fully spread; the prominent display or flashing effect of the colour pattern of red, white and black presumably confused or deterred the predator.

Its large wings also enable the Wallcreeper to hover. Moreover, they make it superbly agile and manoeuvrable in the air, especially when pursuing insects, allowing it to fly in curves and turns within a very small space. When inexperienced young captive Wallcreepers were first released into the aviary, the rear wall of which consisted of a large glass pane, Löhr's study window, not once did they collide with the glass. Practising their flying skills, the young would sometimes head for the glass at a speed that forced the observers on the other side to hold their breath, but the birds would always veer away within just centimetres of the obstruction. Such remarkable agility also means that, in the wild, Wallcreepers are able to evade most attacks by predators.

The characteristic wing-flicking is a striking feature of the Wallcreeper's behaviour, and the proportionately large size of the wings makes this action slower than in most other bird species. The constant flicking action can suddenly change an inconspicuous bird that merges perfectly with its background into a very conspicuous one, as the otherwise concealed white spots on the primaries flash and the red parts of the plumage are visible over some distance. This visual signal, which is important as the principal means of communication, is discussed in more detail later (see General Habits).

The black bill is long, slender, rounded, slightly decurved and sharply pointed. It is used for the purpose of extricating insects and other arthropods which have concealed themselves in holes and crevices, the very narrow head being often inserted deep into such cavities. Located near the thicker base of the bill, the nostrils are long and narrow and partly covered by a membrane above. The tongue, too, is long, thin and pointed, and is also divided, or "barbed", at the tip (see Food and Feeding). The eyes are black and are conspicuously positioned so as to allow the bird to focus both eyes simultaneously on a prey item adjacent to the tip of its bill. Löhr noted that a captive Wallcreeper looked rather like an owl (Strigidae) when staring straight at the observer.

Strikingly large feet are another characteristic feature. The black legs and toes are, however, relatively long and thin, something which surprised G. Mountfort when he saw a Wallcreeper in the hand in Pakistan, as he would have expected such a rock-climbing species to have short, sturdy legs like those of a nuthatch. The claws are strong and sharply decurved, the long hind claw, as long as or longer than the hind toe, being slightly less decurved than the others.

The Wallcreeper's method of climbing differs from that of other bird species. Although it may occasionally climb in the manner of a nuthatch, placing one foot higher than the other, it usually hops, with the feet held parallel, from one jutting rock to the next. The gait, on both vertical and horizontal surfaces, is mainly a short, jerky hop varied by sidling, creeping and walking. The species will walk for short distances in crevices and when entering the nest-hole, and also in order to retrieve small pieces when dismembering prey items (see Food and Feeding). Alternate walking and hopping also occur. It can jump up a step of about 20 cm without using its wings. When forced to climb up a vertical rock face and to cross relatively smooth walls without ledges or projections, however, the bird does bring its wings into play, whereby one wing may be twisted in a peculiar way. In some cases, a single rapid wingbeat is enough to support an ascending leap. These movements of the wings have nothing to do with wing-flicking. Saniga observed Wallcreepers which climbed upwards under overhanging rocks, often assisted by vigorous wingbeats. If the bird has to ascend quite a long way, it will take off from the rock face and fly upwards in a spiral. Frequent clinging to the wall between individual climbing phases is typical when a bird is moving over longer stretches.

Wallcreepers probably never attempt to land on a vertical rock face lacking structural features such as grooves, overhangs, ledges or the like. Captive individuals certainly did not try to land on a smooth vertical surface, but they managed to do so

easily on a house wall with roughcast rendering; even so, they would cling to the latter much more frequently than try to climb on it, something easily achieved without the need to use the wings by treecreepers and small nuthatch species. It is by no means rare to see a Wallcreeper slipping down on a smooth slab of rock, but the species very quickly makes use of its wings to stop itself from falling. The difficulty which a Wallcreeper has, and the ponderous and clumsy appearance which it can present, when trying to climb walls with a smooth surface were strikingly revealed in observations on a pair that nested in the wall of the castle Neuschwanstein, in Bavaria (see Relationship with Man). These two individuals certainly did not attempt to climb straight up the castle wall, but fluttered rather in a rectangular recess, moving alternately from one side to the other and thus ascending in a zigzag. They would always then cover the last stage in short flights. As the Wallcreeper clings to a cliff with the feet parallel and without being able to use its tail as a prop, it counterbalances by bringing its breast as close to the substrate as possible, thereby shifting its weight in the front part of its body towards the rock face, which the feathers sometimes touch. The long toes and claws help it to do this. Wallcreepers can also climb trees, but they do this only rarely (see Habitat).

In breeding plumage, the adult male's forehead, crown, upper ear-coverts and mantle are ash-grey, the head being slightly darker than the mantle, which may fade to whitish-grey with wear and thus contrast with the medium to dark grey or blackish-grey of the lower back, rump and uppertail-coverts, and the dark tail. The lesser and median wing-coverts are reddish-pink, and the greater wing-coverts and primary coverts are black-brown with a red-pink outer web. The outermost primary is blackish-brown. The other primaries are blackish brown-grey, with a red-pink basal half of the outer web and a whitish fringe along the tip; each of the outer primaries (except the outermost) has two large oval white spots on the inner web, but the inner primaries have only one white spot or none at all on the inner web; some birds also have rusty spots randomly distributed on the inner primaries. The inner web of the secondaries is unspotted or with one reddish-yellow or rusty spot. There is some variation, apparently not sex-related, in the number and size of spots on the flight-feathers. The white tips are sometimes absent, whereas in juveniles they tend to be broader. The tail feathers are slate-black with a grey tip, the two outermost rectrices having a white patch. The male's throat, cheek and chest are black, with some individual variation, and the rest of the underparts are grey, the undertail-coverts tipped white.

In breeding plumage the female resembles the male, except that the throat and chest are sometimes white, although usually with a dark grey or grey-black mottled patch of varying size on the lower throat or chest; this extremely variable feature, which is rarely almost as extensive as shown by the breeding adult male, is not age-related. Overall the female appears paler than the male, with much of her plumage slightly paler grey.

The sexes are indistinguishable in adult non-breeding plumage, which resembles that of the breeding adult female except that it is uniformly creamy white or white from chin to chest. Thus, the breeding male's large black bib and the small dusky spot of most females in breeding plumage are lost; the underparts are otherwise medium grey. The forehead and crown are light or medium grey with a faint buff-brown tinge, and a narrow off-white eyering is more obvious than it is during the summer.

Juvenile Wallcreepers are not unlike non-breeding adults, but appear darker ash-grey over the entire body plumage. The black bill is initially almost straight. In first-winter plumage, the forehead and crown are tinged brownish, later becoming grey.

Geographical differences are rather slight. The eastern subspecies, *nepalensis*, differs from the nominate race only in being on average darker, with the upperparts slightly darker, more bluish-grey, and the belly sometimes darker grey or blackish. Its forehead and crown are often tinged yellow-ochre or buff-brown in winter, and the base of the tail feathers is more often tinged pink. In addition, the pale spots on the primaries and tail are on average larger than those of the nominate race, while the wing is on average longer and the bill shorter.

Flight-feather moult takes about eight weeks, and it may begin when the adults still have young in the nest. The female of a

When breeding, the male Wallcreeper has the chin, throat and breast black, but outside the breeding season both sexes have this same area mainly white. The breeding female's plumage is similar to this "unisexual" non-breeding dress, but with a variable grey-black patch on the throat. The right-hand bird might appear to be a breeding female, but the photo was taken in November: this bird has moulted into non-breeding plumage and simply happens to have a few dark feathers showing through on the throat.

captive breeding pair, the young of which fledged on 6th and 7th July, shed the first primary on 30th June, and both adults had moulted the first pair of primaries on 1st and 2nd July. The female of a wild pair under observation in the Ötz valley, in Austria, also shed the first feather during the nestling period, which is rather unusual for a passerine. The speeding-up of the moult process, however, is to be explained by the fact that the onset of winter is often early in the mountains. During this moult of the remiges and rectrices, Wallcreepers do not undertake long flights but they tend, rather, to spend much time by mountain streams and on grassy ledges. Aviary-held Wallcreepers, likewise, completely abandoned their habitual "aerial play" during this period.

In the 1970s, as it had not been established whether all the small body feathers are shed during the spring moult into breeding plumage, Löhrl colour-dyed a Wallcreeper with a red pigment. It was subsequently revealed that the only feathers moulted were those of the throat, the breast and the front part of the upper head, with the forehead and sides of the head, and also some feathers on the upper back. The Wallcreeper thus moults only those plumage parts that change colour in the male and in at least some females when breeding plumage is assumed. Despite this, the pre-breeding moult of the small body feathers lasts for six weeks, that of one captive individual continuing from 8th February to 22nd March.

Post-juvenile moult begins about four weeks after fledging and is restricted to the body plumage, thus excluding the flight-feathers and the tail. The red parts of the plumage remain an intense red.

Habitat

The Wallcreeper is probably Eremian (of the Palearctic arid zone) in origin. It is found in temperate, boreal and steppe climatic zones and mountain regions of the south Palearctic, where it is often present near glaciers or just below the snow-line. It breeds mainly in rocky terrain in high and medium-altitude mountains from Spain eastwards to China, effectively replacing the Western Rock (*Sitta neumayer*) and Eastern Rock Nuthatches (*Sitta tephronota*) in cooler, higher and less sunny zones. Its preferred habitat is varied rocky regions, typically craggy and fissured, steep cliffs

and boulder-strewn slopes, very often with running water though this is not a precondition, and interspersed with grassy ledges that harbour insects and spiders (Araneae); other vegetation characteristic of this species' habitat, including moss patches, herbaceous plants, shrubs and trees, similarly attracts the invertebrates on which Wallcreepers feed. Breeding habitats in southern Greece, and some in Slovakia, conspicuously lack the waterfalls and streams typical of breeding sites in the Alps. The varied nature of the nesting territory, including the fact that it contains both sunlit and shaded parts, is a guarantee that sufficient food is available at any time of the day and in all types of weather (see Food and Feeding).

Nineteenth-century reports of Wallcreepers in trees have been confirmed more recently, albeit rarely. An individual was seen to forage successfully on a young arolla pine (*Pinus cembra*), staying on the trunk and/or jumping from branch to branch, and there are further observations of such behaviour in the former USSR and in Kashmir, where one also regularly visited the wooden walls of a houseboat. It has even been reported that Wallcreepers wintering at lower altitudes in Tajikistan frequently forage in orchards, but it is not clear whether they actually spend long periods on trees. In his Slovakian study, Saniga observed that Wallcreepers pursued by other species, such as the Common Swift (*Apus apus*), or overtaken by stormy conditions with downpours sought refuge in trees. In the same study, it was found that they will also perch in trees in order to preen, and that the first flight of fledgling Wallcreepers is often to a tree. The difficulties that the species may face when climbing on trees became clear when several of Löhrl's captive individuals, the aviary of which contained an old apple-tree trunk, sometimes got their long, curved claws briefly caught in its bark when they wanted to continue climbing or to fly off.

Breeding sites are on rock faces up to 900–1100 m high, the lower part of which may be open or densely wooded, and in the low rocky sides, up to about 20 m high, of shady, damp gorges carved out by mountain streams, where the nest may be constantly in spray, so that the ambient climate varies considerably. For those Wallcreepers breeding in gorges in Europe, Löhrl noted persistent foraging in rubble along streams and rivers, especially in poor weather conditions. The species will also nest on, and occasionally inside, a variety of buildings, including castles,

churches, mountain huts and barrages (see Breeding, and Relationship with Man). The geological formation is unimportant or, at least, is less important than is a markedly structured surface with overhangs, crevices, fissures, ledges and vegetation. Wallcreepers will occupy sites on cliffs both of limestone and of ancient crystalline rocks such as granite and the metamorphic gneisses, although limestone is sometimes reported as being preferred, as, for example, in Spain, Slovakia and Tibet, and may well provide a better supply of potential nest-sites.

Nor is there a fixed altitude. Breeding has been recorded in Spain at a mean of 1839 m, in France from 480 m to 2840 m, in Switzerland from 350 m in the canton of Ticino up to 3450 m, most sites lying between 1200 m and 2300 m, and in Austria between 450 m and at least 2500 m but mainly at 1000–2000 m. The small German population, in the Bavarian Alps, has an altitudinal range extending between 660 m and 2450, exceptionally to 2900 m, while Wallcreepers breeding in the Slovak West Carpathians have been found between 400 m and 1500 m in the Malá Fatra and at 650–1550 m in the Vel'ká Fatra, and pairs in southern Greece at 1900–2400 m. Most breeding sites in Turkey lie between 2300 m and 3100 m, and the majority in the Tien Shan are probably at 3000–3500, with extremes of 2800 m and 4000 m, the altitudinal limits in north-eastern Afghanistan being similarly at 2900–4100 m. This species breeds at up to 4700 m in the Pamir Mountains, and in the Himalayas in general Wallcreepers probably breed primarily above 3600 m and up to the permanent snow-line. They have been observed at up to 5100 m in the Tibetan region. Even at great heights, there are still refuges sufficiently warmed by the sun to create a favourable micro-climate for various nival (snow-adapted) insects on which Wallcreepers can feed. The Wallcreeper's wing shape is superbly well adapted to its typical mountain habitat, as the species can exploit the updraughts by sheer rock faces to ascend to higher regions much more rapidly than would ever be possible by using active flapping flight.

Typical haunts in winter are rock faces, including quarries and sea cliffs, earth and clay banks or cliffs, newly built road cuttings, and buildings such as churches, cathedrals and ruins. In Gilgit, in north Pakistan, Wallcreepers visit stone walls along roads, as well as buildings, in the winter months. In Nepal, they regularly visit horizontal gravel fields and rock debris by cliffs and, at low altitudes where rock faces and cliffs are absent, they come to banks and fields of gravel along rivers; at the other extreme, they have been seen to forage systematically on the gently sloping lateral moraines of glaciers at nearly 5000 m in the Khumbu Himal. A Wallcreeper's winter territory may comprise several small sections of rock face or quarry, but the territory-holding individual may intermittently cease foraging there and fly off to visit ruins, churches and similar buildings. Those migrating between their breeding and winter territories sometimes stop off on structures such as bridges and power stations.

Wintering Wallcreepers are found down to sea-level, as on some Mediterranean islands and in southern Turkey, and in the Indian Subcontinent they occur in the plains of India and Pakistan, and to 245 m in Nepal and 305 m in Sikkim. Sheer limestone cliffs favoured by this species in Anatolia, in central Turkey, are at 500–700 m on the edge of the steppe. On the other hand, Wallcreepers have been recorded at considerable altitude during the non-breeding season. For example, they have been observed at 1800–3200 m in Switzerland and, in the range of the subspecies *nepalensis*, at 1200–2400 m in the northern valleys of Pakistan, at 4000 m in Ladakh, up to 5730 m in Nepal, to 3600 m in Sikkim, and usually above 1000 m in Bhutan. In China, there are February records of *nepalensis* at 1400–2500 m in Sichuan and 2925 m in Yunnan.

General Habits

Breeding pairs of Wallcreepers are solitary and strictly territorial, and these birds are normally solitary also in winter, when the sexes are identical in plumage (see Morphological Aspects) and vigorously defend individual feeding territories, the size of which varies and/or is difficult to assess, against other Wallcreepers. A non-breeding territory may comprise a single rock massif or, not

uncommonly, a large quarry of 10 ha or more, or it may be more fragmented, taking in, for example, several quarries or parts of buildings. An individual wintering in a Belgian quarry at Poulseur frequented a rock face about 100 m long and 40 m high. In Switzerland, R. Hauri noted that Wallcreepers wintering in towns and on rocks had a focal point of activity and undertook set movements each day. Relatively long flights, covering up to at least 1.6 km, from the roost-site to visit quarries and buildings were reported by H. Stopper in Germany, while Saniga noted that dispersal from roosts in Slovakia was within a radius of about 4 km, and once 6 km. Winter site-fidelity has been proved in a couple of cases, and seems likely in others (see Movements).

In Hauri's study at Mitholz, in southern Switzerland, it was found that the occasional occurrence of a second individual in a winter territory invariably led to a dispute. When two to four or more Wallcreepers are reported as having been seen "together" in winter, it is not always clear how closely they were associated. On clay cliffs at the Shardara Reservoir, in southern Kazakhstan, as many as 15–18 Wallcreepers, single individuals and "pairs", were found during the course of two days in December. Before the juvenile moult, independent juveniles, possibly siblings, occur in loose groups, which keep separate from any adults that may still be present in the breeding area; they are generally solitary after one month, at the latest. There are four published reports of apparent flocks outside the breeding season in the western French Alps: these involved a group of six individuals in mid-August, and ten, dispersed over a few tens of metres, late in the same month; a flock of 48 which landed in an area 10–15 m across on a sunlit rock face on 10th December; and about 70 individuals, in two loose gatherings, on 11th November. In addition, 40–50 foraging Wallcreepers were observed above Ausserbratz, in the Austrian province of Vorarlberg, in October 1990. The well-known intolerance of this species towards conspecifics (see Breeding), however, may lead one to conclude that such reports are not credible, and U. N. Glutz von Blotzheim considered that, in future, similar reports should, in any case, be thoroughly investigated before publication.

Wallcreepers are generally fairly confiding both within and outside the breeding season, tolerating or being indifferent to the presence of humans. Nevertheless, when conducting prolonged observations on breeding birds in Austria, even from the opposite side of a gorge, C. Böhm found that they tended to hesitate before going to the nest or used a roundabout route to reach it. There are many reports from mountaineers of close encounters with this species, and individuals spending the non-breeding season in towns are often not shy. Indeed, the species is sometimes described as being tame, which may be especially true of vagrants. On the other hand, it will hide when it becomes aware of being watched.

During the daytime activity period, Wallcreepers appear to concentrate on the vital forms of behaviour such as foraging and, in the breeding season, searching for nest material, nest-building and the care of the young. Both wild-living and captive Wallcreepers often take long breaks, which usually begin with preening and then lead to complete rest. After such periods of rest, which can last for ten minutes or longer, the bird begins to stretch: the wings and legs are extended backwards, always one at a time, and then both wings are flicked upwards.

Saniga's detailed investigation of this species in central Slovakia confirmed the important role of the photoperiod in the timing of activity throughout the year. Wallcreepers go to roost relatively early, and they rise late. Saniga found the roosting period to be longer than that of other species sharing the same habitat, such as the Common Rock-thrush (*Monticola saxatilis*) and the Alpine Accentor (*Prunella collaris*). One aviculturist commented on the fact that captive juveniles apparently needed long periods of deep sleep. At an east-facing rock wall in Switzerland that was poorly illuminated by the sun, the bird entered its roost-hole an average of 7–8 minutes before sunset, whereas the average time on west-facing cliffs was 11 minutes after sunset. Of course, the weather and the degree to which the individual bird is sated also play a part. While solitary roosting is certainly the norm, there is a January report of five Wallcreepers roosting together under the roof of a building in Stans, in the Swiss canton of Nidwalden.

The plumage of the **Wallcreeper** is a beautiful combination of grey, black, white and carmine-red that serves both to conceal and to reveal. Its grey head and body with black countershading can make it surprisingly difficult to see against rocks and cliffs, but as soon as it flicks open its wings or flies, it immediately becomes strikingly visible. Irrespective of age or sex, the Wallcreeper has bright carmine-red coverts both above and below the wing. On the upperwing, this shock of colour extends onto the inner primaries and secondaries, in the form of fringes. An array of white spots on the flight-feathers further heightens the splendid show. The beauty of this combination is put to good effect by the Wallcreeper's erratic, butterfly-like flight, as it bounds and flits on disproportionately large, long and rounded wings, rather like a Hoopoe (*Upupa epops*). The wing shape and large surface area enable the Wallcreeper to take advantage of the updraughts prevalent in mountainous areas, which billow it upwards to higher feeding grounds using minimal effort on the bird's part.

Wallcreepers are very demanding in their choice of a cavity for roosting. The hole should be inaccessible to predators, it must remain dry and it must provide protection from the wind; further, it must not freeze up in snowstorms. Most of the sites chosen for roosting are fairly small holes or crevices under rock overhangs. Holes recognized as favourable roost-sites are often used repeatedly for weeks, and one site on molasse cliffs in Switzerland was utilized by different individuals over several decades. At a mountain locality near Almaty, in south-east Kazakhstan, Wallcreepers descended in the morning but moved back upslope in the evening, presumably preferring to roost in secure sites higher up the mountain. According to Girtanner and F. C. Keller, Wallcreepers lie flat on the floor of their roost-hole when sleeping, but one of Löhrl's captive individuals, roosting openly on a brick high up on the wall of the aviary, slept in the same way as other species, sitting upright with the head tucked into the back feathers, and the ruffled contour feathers covering its feet; this posture had already been confirmed for another captive bird by O. and M. Heinroth.

This species readily sun-bathes when it feels secure. In the first of two different postures commonly adopted for sunning, the Wallcreeper sits upright, with its underparts exposed to the sun, usually closes its eyes and holds its head at an angle and sometimes also thrown back, with the throat feathers ruffled and lit by the sun; all parts of the plumage exposed to the sun are conspicuously ruffled. In the second posture, it spreads its large, colourful wings to the fullest extent and allows the sun's rays to penetrate its back feathers, the preen gland being fully exposed; the eyes usually remain open in this posture, while the head is often lowered and supported on the bill. For sunning, these birds will also cling to a rock face with the wings held open. The Wallcreeper's performance of dusting or sand-bathing, which frequently alternates with sunning and for which it prefers stones or rocks covered in a thin layer of sand, also differs from that of other birds. The individual lies flat on the rock, supports its head by resting the bill on the substrate, and makes alternate kicking movements of the feet to the side or at an angle to the rear. The jerky movements executed bring the body directly into contact with the rough sand, and the bird, supporting itself on its half-open wings, moves slowly forwards. Wallcreepers tend to increase sunning and dusting behaviour during the moult. For water-bathing, the species prefers water running downwards from a higher site, while bathing places in standing water are less favoured. A Wallcreeper will stand in the water, immerse its breast and allow the water to trickle over its back, this being accompanied by vigorous beating of the wings. Bathing in snow has also been recorded.

Preening is performed in the usual way. The Wallcreeper cleans its head by scratching, for which it uses the indirect method, the leg being brought up over the wing. On some occasions, however, the bird cleans its head by rubbing it against a stone.

Wing-flicking is a particularly striking and characteristic feature of this species' behaviour, and is often what draws an observer's attention to the bird's presence. Wallcreepers wing-flick at varying intensity, depending on whether they are alone or in twos, are searching for food or are resting. The wing-flicking is not tied to any particular situation and may well be, as is so with most other birds that perform it, an expression of excitement, comparable to, say, the tail-shivering of redstarts (*Phoenicurus*). Although Wallcreepers wing-flick when foraging, they do so also at other times, so that this action is not, despite the contrary view expressed earlier by A. K. Müller and more recently by Saniga, primarily a foraging aid. Even nestlings wing-flick as soon as they leave the nest, albeit for only a few seconds, but they do not flick their wings when in the nest. During wing-flicking, the otherwise concealed white spots on the primaries flash and the red parts of the plumage are visible over some distance. This visual signal serves as a substitute for contact calls, and thus plays an important role in the species' social behaviour as the principal means of intraspecific, and interspecific, communication. The speed and the direction of movement are an indication of the degree of excitement: the more excited the bird, the faster and more upward the wings are flicked.

At the approach of a terrestrial predator such as a stoat (*Mustela erminea*) or a pine marten (*Martes martes*) or beech

marten (*Martes foina*), a Wallcreeper will wing-flick at a faster rate and with the movement directed more upwards, this serving as a warning to the bird's mate. Should the predator vanish into cover, the Wallcreeper will fly to a place from where it is better able to keep the source of danger in view. At the approach of a man and his dog in a quarry near Hallein, in the Austrian province of Salzburg, where a male Wallcreeper was spending the winter, the bird flew down to a large stone on the ground and there watched the dog while wing-flicking; it then returned to the rock face. Löhrl witnessed an incident in which a female Wallcreeper that was dust-bathing on a sloping rock in full sun came within a split second of being seized by a stoat.

When an aerial predator such as a Eurasian Sparrowhawk (*Accipiter nisus*) or a Peregrine Falcon (*Falco peregrinus*) appears, wing-flicking first ceases completely. If the predator attacks, the Wallcreeper will fly up and seek to distract and confuse the hawk or falcon by performing skilful flight manoeuvres, the result of which is frequently that the raptor gives up; the action of drifting in the wind "like a falling leaf" is apparently also employed as an anti-predator strategy. Having thwarted such an attack, one Wallcreeper remained clinging motionless to the rock face for 14 minutes (see Morphological Aspects).

Saniga also observed that Wallcreepers sometimes suspended their climbing activity and the flicking movements of the wings and tail in order to look around for prey or for a new place in which to forage.

Voice

Compared with many other passerines, the Wallcreeper has only a small repertoire of vocalizations. On the breeding grounds, the expressive visual signals (see Morphological Aspects) act as a substitute for vocal communication over quite long distances in places where the voice could not penetrate because of the loud background noise of rushing water and wind. A study by J. Martens and G. Geduldig in Nepal showed that the Wallcreeper's song is not well suited to the environment of Himalayan torrents, and often it was only the highest note that was audible in such conditions. Indeed, movements of the bill or neck may be the sole indication that a Wallcreeper is singing. A male observed in the Spanish Pyrenees, clearly singing to advertise his territory, did so mainly away from the nest-hole during building and was audible at distances of up to 150 m, while two males in Switzerland were recorded as countersinging in July. Near the nest-hole, however, the song serves to attract a female and for nest-showing. In studies of captives, it was found that at a later stage in the breeding cycle, when the young were 12 days old, the male would utter the full song phrase several times daily from within the cavity.

Females also sing, mainly to advertise a winter territory, typically giving a shorter and faster phrase. An analysis of some recordings suggested that members of a pair may sing in duet, but this is one of several topics requiring further investigation.

The full song of the male Wallcreeper consists of an ascending series of melodious, piping and rather flute-like whistles, tending to be hoarse at the start; these are followed by a lower-pitched final note, which may be connected to the piping phrase or isolated. This song phrase is sometimes rapidly repeated over a period of several minutes. Both sexes will also utter an abbreviated version, the "warning song", when they are disturbed near the nest, and a similarly shortened version is given at times of low motivation, as well as at the beginning or the end of the song period. Males and females live in separate winter territories (see General Habits), and the advertising song given there is frequently incomplete, the lower final note being omitted. On the basis of a recording made in the Nepalese Himalayas, the song of the eastern subspecies *nepalensis* exhibits a similar pattern of low-pitched but ascending whistles, but apparently with a larger frequency range than that found in the song of European Wallcreepers.

Other songs, or vocalizations with a song-like structure, have been reported and, in some cases, tape-recorded, but a full analysis is still awaited. There are references to drawn-out, strained glissando whistles, one note typically rising and the next falling. Other components of such vocalizations may include twittering,

For a species that inhabits large territories with abundant background noise caused by strong winds and running water, communication tends to be more visual than vocal.

A **Wallcreeper** is thus more likely to become aware of the presence of a conspecific through seeing the bird flick its wings than by hearing its song. In fact, one study revealed that only the highest note of a Wallcreeper song was audible to the human ear above the sound of a rushing Himalayan river. Nevertheless, Wallcreepers appear not to be greatly deterred by such aural interferences and are fairly vocal birds. Both sexes sing, the female mainly doing so to defend a winter territory. The male's song, normally given while perched or climbing, is a series of clear, flute-like whistles that ascend in pitch until the final lower note. The female's song is shorter and quicker. When alarmed close to the nest-hole, either sex may give a curtailed version of the song as a warning. Wallcreepers are often vocal during courtship, birds uttering chirps that recall a Eurasian Tree Sparrow (*Passer montanus*); prior to copulation, the male sings for an extended period, his neck outstretched and wings drooped by his sides. Young Wallcreepers also sing, once they have completed their post-juvenile moult, their vocalizations gradually becoming adult-like over time.

 Hüttenmoser]

throaty and other whistling sounds reminiscent of the Common Starling (*Sturnus vulgaris*), as well as obvious contact calls and threat calls. Short, more chattering-type songs are characteristic of, for example, high-intensity territorial excitement.

Young Wallcreepers first give a juvenile song, in which the final form is soon recognizable, after completion of the post-juvenile moult (see Morphological Aspects). They perhaps learn the song from the male when he sings at the nest in the second half of the nestling period. It is perfected from October onwards, being in the early stages a mixture of twittering sounds, especially from the female, and attempts to form the typical ascending series of whistles.

Wallcreepers sing mainly when perched or climbing. The male will sing also when in flight, particularly when performing the nest-showing display. Males deliver their full song in the period from May to July.

There are no specific excitement calls or alarm calls in the Wallcreeper's repertoire, a phenomenon that is probably a consequence of the species' solitary way of life. Reports of a "sharp alarm-call" are more likely to refer to the highest note of the song, which, as intimated above, may be the only one audible if the bird is some way from the observer and there is interference from background noise.

The contact call, which is restricted to the breeding season, is a short, quiet chirping or chirruping sound, rendered variously as "tsche", "chup" or "zui", "tui", "pli" or "touiht", and with some resemblance to the "tschirp" or "schilp" nest-call of the Eurasian Tree Sparrow (*Passer montanus*). Transcriptions suggest the existence of two variants, but there is no further evidence to support this. This call serves also as a feeding-call, being given by the male when offering food to the female or by either parent when encouraging the young to gape. Threat calls are given increasingly from the end of the chick-rearing period, as the frequency of the contact call fades. These are described as rolling and relatively impure, and they include a buzzing sound descending in pitch; another threat call rises and then falls in pitch, "chuit dweeoo", the latter part being reminiscent of the whistle made by a Eurasian Wigeon (*Anas penelope*). Directed at conspecifics, for example when uttered by the more aggressive member of a pair at a given moment, threat calls have the effect of maintaining or increasing the distance separating the individuals.

Even day-old chicks emit very faint and delicate, thin, high series of "psi" or "zi" sounds as food-begging calls. These steadily increase in volume and shrillness with age until they become so loud and screeching that they could theoretically betray the location of the nest. Juvenile contact calls, given just before and, more loudly, after fledging, are similar to or perhaps even identical to those of the adults.

Food and Feeding

At all times of the year, Wallcreepers eat only invertebrates, mainly insects in all their development stages and spiders, but there are no detailed studies of the diet of wild individuals. The species is typically solitary when foraging, and it is rare for pair-members to forage together.

Small items, such as wind-blown aphids (Aphidoidea) and, along streams, probably mainly chironomid midges, are picked up from the surface, whereas concealed items are extracted from cracks and crevices, and also from grassy and mossy patches, while the Wallcreeper is climbing, hopping and walking on rock faces. In Saniga's study in the mountains of central Slovakia, for example, these birds spent 85% of the foraging time in moving along rock faces. Wallcreepers will investigate horizontal fissures and vertical crevices by walking along the entire length of these, and hammering vigorously to loosen any obstructions, which it then removes with the bill. A foraging individual often pokes its head into a cavity so that it seems to disappear completely. During the non-breeding season, Wallcreepers foraging on the weathered limestone cliffs of a quarry at Rottenburg, in southern Germany, successfully extracted several leaf-cutter bees (*Megachile*) and a live peacock butterfly (*Inachis io*) from a deep crevice. In winter, especially, this species often carefully investi-

gates the roofs of cave-like hollows. It will also forage on the ground, notably above or next to a rock wall, and, particularly in rainy weather, visit scree under overhanging rocks or along the banks of streams, vanishing under large pebbles and between boulders and examining all manner of tunnels. Portenko reported individuals as perching on stones in mountain streams and catching freshwater shrimps (*Gammarus*), and in south-west Russia another one, which was fluttering about on a clay bank by the Sea of Azov, at times entered old nest-holes of European Rollers (*Coracias garrulus*), spending about nine minutes inside one of these. A pair of Wallcreepers nesting on a building in Switzerland, at some 900 m across a valley from the nearest rock faces, foraged among rubble and roots close by. Farther east, at the Ngozumpa and Khumbu glaciers, in Nepal, after the breeding season, G. Diesselhorst frequently saw what were probably juveniles of the local subspecies *nepalensis* as they systematically foraged in a fluttering motion on the lateral moraine's steep slopes of coarse till material. When searching for food on the ground, a Wallcreeper will sometimes turn over the leaf litter and small stones, using the closed bill for this purpose.

Being completely dependent on animal food, Wallcreepers make full use of the fact that some parts of their rocky habitat are in the sun and others in the shade. In the morning they first visit sunlit surfaces, later moving to shady places where insects, often still torpid, are easier to catch. At such times, foraging Wallcreepers will hurry from one shaded rock face to the next and overfly sunlit parts.

Insects, especially just after they have taken off, can be overtaken and caught in flight by these birds. Alternatively, a Wallcreeper will hover to glean them, as well as spiders and small molluscs, from rock walls and overhangs; ascending flights in pursuit of butterflies are usually unsuccessful. There is an exceptional record of a female catching exclusively flying insects near the nest for about two hours. In Slovakia, Saniga's study suggested that small insects are flushed by the bird's wing-flicking actions (see General Habits) and are caught immediately on the rock or in the air, such captures accounting for 5% of the bird's time spent in foraging; Wallcreepers also caught prey in longer flycatching sallies and by hovering, which accounted for, respectively, 7% and 3% of the foraging time. In late July, at 3450 m on the Vouasson glacier, in Switzerland, a single Wallcreeper was seen to fly above zygaenid moths, which were clearly numb and slow-moving at that altitude, and force them down so that they could be picked off the snow-covered ground; similarly, W. Wüst reported wind-blown moth larvae (of the family Arctiidae) being taken from the snow. Insects in a torpid state because of the cold are clearly vulnerable, and there are records of Wallcreepers taking such insects from plants, such as a young arolla pine, and from cracks in window frames.

Having been seized in the bill tip, impaled on the long and barbed tongue and drawn back through the almost closed bill, small insects are swallowed immediately. Moths taken for the adult's own consumption may, if not too large, be swallowed in their entirety, complete with the wings. In general, however, the Wallcreeper prepares large items before swallowing them or, especially, feeding them to the young. It may turn and shake the item in order to position it crossways in the bill and, after sideways beating against a rock, the duration of which varies depending on the size and toughness of the item, toss it back and swallow it with a forward-and-backward movement of the head, similar to the action of a Hoopoe.

When dealing with insects such as grasshoppers and crickets (Orthoptera) and noctuid moths, the Wallcreeper carries the prey to a horizontal surface, for example a quite large stone or a flat piece of ground, and there dismembers it. Holding the insect at the base of the wing or a large hind leg, it beats its victim against the substrate until the wing or leg breaks off. As the insect's body is propelled away in this operation, the Wallcreeper will immediately retrieve it and repeat the process with the other extremities. An individual in a southern German quarry took 2–3 minutes to deal with a peacock butterfly. Orthopterans are usually subjected to additional hammering with the bill tip in order to soften them up. Interestingly, when aviary-held captives received no prey items requiring the kind of preparation described, they would treat sub-

stitutes, such as small pieces of wood, in the same fashion. Spiders, harvestmen (Opiliones) and crane flies (Tipulidae) are swallowed or carried to the nest to be fed to the young whole.

Indigestible chitin fragments are regularly ejected as pellets, sometimes of considerable size. Those produced by three captive juveniles were rather dry, and were up to 2 cm long and 1 cm in diameter. Prior to ejecting a pellet, a Wallcreeper will suddenly become still, repeatedly open its bill, and then rapidly shake the head to flick the pellet away.

Wallcreepers drink regularly, by dipping the bill into water and then raising the head. They appear, however, to prefer sites where they can catch falling drops of water in the bill by holding up the head. Captives in aviaries always took fresh snow in preference to water provided in bowls, and they even carried snow to a bare stone in order to break it up and consume it in very small portions.

Especially for feeding to the young, Wallcreepers take small to very small insects, but also some larger items. The latter include in particular lepidopterans such as moths of the family Noctuidae, and also small tortoiseshell butterflies (*Aglaia urticae*), and these can sometimes be identified when they are carried to the nest. On the basis of information from European and Central Asian sources, the invertebrate diet incorporates damselflies (Odonata), stoneflies (Plecoptera), grasshoppers and crickets, earwigs (Dermaptera), hemipteran bugs, adult and larval Lepidoptera, and dipteran flies including crane flies, robber-flies (Asilidae), hoverflies (Syrphidae) and house-flies and kin (Muscidae), as well as ants and bees (Hymenoptera) and beetles of the families Curculionidae, Carabidae, Staphylinidae, Scarabaeidae and Elateridae; other items include spiders, harvestmen, ticks (Acari), woodlice (Isopoda), freshwater shrimps, centipedes (Chilopoda), and small molluscs. One Spanish study mentions that unidentified seeds were found in the stomach of a male Wallcreeper in September, but these may have been taken accidentally.

Breeding

Wallcreepers are monogamous, and the pair-bond is severed after the breeding season. Saniga recorded two cases of two females, the nests of which were about 800 m apart, apparently paired with the same male; he fed both females during incuba-

tion, but helped to feed the young at only one nest, while the other failed. Both sexes show an increased readiness to fight just before the onset of winter, and they are highly aggressive and intolerant of conspecifics outside the breeding season. Both defend individual winter territories, and the female is no less aggressive than the male in defence of hers. The sexes meet again when the birds return to their breeding grounds in the spring. There are quite frequent reports of roving single Wallcreepers or pairs in full plumage. These may be Wallcreepers which have failed to establish a territory in an area of high density and thus represent a reserve of potential breeders, or they are perhaps not yet old enough to breed. Such unpaired individuals sometimes associate with an established pair, but it is not clear how closely they do so.

Saniga studied a widely scattered and sparsely distributed population of 12–18 pairs in the Vel'ká and Malá Fatra mountains, in the Slovak West Carpathians, where there were 1–3 pairs at each locality. His use of individual colour-ringing revealed a high degree of site-fidelity and mate-fidelity, and also demonstrated that juveniles were faithful to the natal site. All of the marked breeding individuals for which there were repeated observations, the oldest ringed bird being eight years old, were found at the same breeding localities or within a radius of two kilometres. Two of four colour-ringed pairs bred at the same site in four consecutive years, and two other ringed pairs occupied the same breeding locality in five consecutive years. E. Bezzel's observations in the Bavarian Werdenfelser Land and a general summary for Bavaria by Wüst showed that some localities had been occupied over many decades. Wallcreepers in Slovakia exhibited a strong preference for particular nest-sites, the same crevice being used, albeit by different individuals, over the course of several years, in one case in nine years between 1979 and 2000, and in another in seven years between 1982 and 1999. In contrast, the more isolated localities were not occupied regularly every year. A "coercion" effect resulting from the limited supply of optimal nest-sites and the fact that Wallcreepers were typically site-faithful increased the probability of former partners meeting each other again before they met other possible partners. Solitary pairs, remote from the main population and thus presumably unaware of other pairs, proved to be members of a single family, the same adults or their offspring returning over several consecu-

One of the primary responsibilities of a breeding pair of **Wallcreepers** is to collect sufficient food to provision the growing offspring. This female, sexed by the black patch on an otherwise white throat and breast, is returning to her brood with a spider and a caterpillar. The large size of the prey items suggests that the offspring may be relatively well grown, as Wallcreepers mainly feed their young with small insects. The extensive territory of a Wallcreeper pair means that it is more efficient for a foraging adult to return to the nest with several prey items, rather than after each capture.

tive years. Successful breeding was recorded in successive years, for one father–daughter pair that bred in 1997 and 1998 and for one brother–sister pair in 1998, 1999 and 2000.

Breeding territories are very extensive, both horizontally and vertically. They are adapted to fit the distribution of rocky areas, and their shape consequently varies. In the Austrian Tyrol, a pair in the Ötz valley, the only pair in the gorge of a mountain torrent, may serve as an indication of territory size: on the basis of the distance flown by the adults when feeding young, this territory was, in seven out of ten years of observation, about 800 m long. Elsewhere in the Ötz valley, the breeding pairs never flew less than 1000–1100 m along the course of the stream. It should be noted, however, that the rocks on the sides of the gorge range in height from only 10 m up to about 150 m. On limestone cliffs in the West Carpathians, Saniga found territories only 350 m and 400 m long and 25–30 m high. Several observers have confirmed that male and female Wallcreepers regularly forage in different areas, the female generally closer to the nest and the male often more wide-ranging.

In order to determine where the territory limits lie, it is essential to be able to distinguish between breeding pairs. Thanks to the marked individual variation in the dark breast patch of the females, this is usually possible without colour-ringing. Males are more difficult to distinguish individually, but even they often exhibit some variation around the edges of the black bib. Pairs are normally separated by a distance of one to several kilometres, as, for example, in Switzerland, where Hauri also considered territories to be probably contiguous over 10 km in the Lauterbrunnental, a valley which has huge cliffs on both sides. Shorter distances between pairs include 119 m in the Ötz valley and 350 m in the Italian Alps, while four simultaneously occupied nests on a more or less continuous rock wall in Slovakia were separated by distances of 800 m, 600 m and 600 m.

It is virtually impossible to determine the exact population density of this species. This is certainly subject to fluctuations but it appears not to have changed in the long term, although it is generally low, because Wallcreepers require a large home range when collecting food for their young. Recent studies indicate that the German population, restricted to the northern Alps, in Bavaria, is likely to consist of at least 100 pairs. Assuming an area of potentially suitable Wallcreeper habitat of about 635 km², out of a total study area of 1440 km², this would give a density of about 5.5–6 pairs per 100 km². In reality, however, the dispersion of breeding pairs depends on the composition of the rock faces and where they are situated, and it is correspondingly uneven. In the Bernese Alps, in Switzerland, the population has been estimated at 200–250 pairs within an area of 2895 km², or 0.07–0.09 pairs/km². Just to the north-east of there, in the Austrian Tyrol, the gorges of the Ache above Zwieselstein, including tributaries, hold a maximum of ten pairs in about 320 km², or 0.03 pairs/km², while in the Italian province of Brescia, on the southern edge of the Alps, 50–100 pairs were reported in 4749 km², the equivalent of 0.01–0.02 pairs/km².

Fights to settle territorial boundaries take place over the course of several days. Such fights are usually aerial and quite often involve three individuals, indicating that females also take part. Once territories are established and delineated, the boundaries are strictly respected, even if they happen to lie close to a later nest-site.

Simple gaping is the lowest-intensity form of threat. This is defensive, and is frequently directed by members of a pair to each other. It serves to maintain individual distance, and is often a sufficient deterrent even when used against larger and more powerful bird species. If a rival is in view at some distance, the Wallcreeper, if ready to attack, will adopt a threat posture similar to that of most nuthatches: the tail is raised and the wings are drooped so that the white spots remain concealed, whereas the red patches on the wings are very conspicuous. Should the rival approach, the wings are spread sideways or raised, the white spots again being concealed, while only the bright red shows up.

If the threat does not achieve the desired end, a fight may ensue. Löhrl never observed a true damaging fight, although he certainly witnessed hectic aerial tussles and chases, and attacks when birds were on rocks; in the latter case, when differences in the plumage pattern allowed the two individuals to be told apart, the

opponents kept on changing roles, one first attacking the other and then being attacked and fleeing. A captive male imprinted on humans regarded its keeper's hand as an opponent, something which did, at least, provide the opportunity to study Wallcreeper fighting behaviour at close quarters. At the moment of launching an attack, the bird lowered its tail, leapt on to the hand, gripped tightly with its claws, which often drew blood, and then hammered away with its closed or slightly open bill; it beat the wings vigorously throughout the attack. A captive Wallcreeper, while chasing another in flight, suddenly had its bill full of small feathers, indicating that it must have struck home and torn these from the other bird.

Interactions with other species take place from time to time. For example, Hauri saw two Black Redstarts (*Phoenicurus ochruros*) accompanying a climbing Wallcreeper and frequently catching insects in flight, these having probably been flushed by the Wallcreeper but not taken by it. This elicited no antagonism on the part of the latter, although Wallcreepers do sometimes chase, and are chased by, Black Redstarts, five of which were once seen to drive a Wallcreeper from a cliff face in Bavaria. Similarly, hirundines, especially Eurasian Crag Martins (*Ptyonoprogne rupestris*), frequently attack foraging Wallcreepers. In another instance, a Wallcreeper, intensively wing-flicking, and a Lesser Spotted Woodpecker (*Dendrocopos minor*) were about one metre apart low on a cliff when the woodpecker attacked; the Wallcreeper took off and hovered nearby, returning to the cliff as soon as the woodpecker had left.

Pair formation takes place after the Wallcreepers return from their wintering grounds, presumably at a nest-hole accepted by both pair-members. Taking off from the entrance to the cavity which he has selected, the male performs a nest-showing flight, alternating gliding and bouts of slow flapping, within a small area, this leading back to the hole after a number of sharp turns and steep ascents and descents. If a female appears, the male will nest-show, singing throughout the performance. Should she then approach, he will enter the hole while singing and continue to sing while inside it; otherwise, he will perform further circular nest-showing flights. Also typical of this period are variants of a head-up posture, which draws attention to the male's black bib, and changes from courtship to threat and chases; in addition, the male switches from nest-showing to courtship-flights, which are slower, but with rapid wingbeats.

As a prelude to copulation, the male sings persistently, with the neck extended forward and the wings drooped. He will then land next to the female, hold the wings spread to the side, and mount her, this accompanied by much vigorous flapping of the wings and attempts to seize the female's head feathers. Copulation is restricted to a period of a few days before and at the start of laying. In all observed cases, the initiative for copulation came from the male.

In Europe, egg-laying takes place from late April to mid-June, depending on the altitude. At 2000 m in the Austrian Tyrol, where the temperature is rather constantly cool, eggs were laid in the first half of June and, over a period of ten years, fledging always took place in the last third of July. Fledging dates noted by Hauri in the Bernese Oberland, in contrast, ranged from 5th July to 8th August, the latest following a severe winter. The breeding season in the Caucasus, and also farther east, in the Himalayas, extends from May to July, although mid-August observations at Mount Khoostoop, in Armenia, included sightings both of fledged young and of a pair still feeding young in the nest.

Because the nest has to be safe from intrusion by mammalian predators, the choice of a good site is obviously of crucial importance. At one nest under observation in the Ötz valley, two stoats demonstrated the ability of this predator to move about on steep rocks. Of 33 nest-holes known to Löhrl, only five were temporarily accessible to martens or stoats, and one of these five was preyed on. Nest-sites used by Wallcreepers include a cleft in a rock face, behind a rock or among boulders or scree, and similar fissures or cavities on or inside buildings, including church towers, ventilation holes and pipes. Nests sometimes have two entrances, one used by the male and the other by the female, or one serving as the entrance and the other as the exit. There is marked variation in the shape of the entrance and of the chamber, but the latter should apparently extend slightly to the rear and

downwards. In the few cases where this could be measured, the nest was about 60 cm from the entrance, but some nests were so far forward that parts of them were actually visible at the entrance. Most of the holes examined by Saniga were protected from above by an overhanging rock, and eleven nests lay 25–75 cm into their respective cavities. In the majority of cases, Löhrl found that the hole entrance did not lie immediately over a sheer drop but was somewhat set back, so that young close to fledging could run to meet their parents just outside the entrance. Such favourable nest-holes are not very common, and Wallcreepers will choose them even if this means nesting on the edge of their territory, suggesting that security against predators has precedence over defence against conspecific rivals.

Only the female builds the nest, although the male often accompanies her, and the main material used is moss, collected when dripping wet and being torn off in a downward-tugging movement. From the start, the material is densely matted together to provide good insulation, the main constituents being plant fibres, feathers, animal hair and wool, lichen, needles of the arolla pine, rootlets and grass. One nest was lined with feathers, hair and a small piece of mouse (Muridae) skin. The cup measures about 6 cm across and the rim is quite thick and solidly built. A female observed near Hecho, in northernmost Spain, picked goat hairs individually from a rock wall by a road and flew, carrying a small bundle of these, to her nest. Remarkably, she also selected discarded cigarette filters, which were abundant by the roadside, the apparent ease and frequency of the ensuing operation suggesting a familiarity with an unusual, man-made source of nest material: each filter was held down with one foot, the paper wrapping torn open, and the soft fibres gathered into a bundle for transport to the nest. The process of nest-building takes about five days, but lining material may still be added after that. The building method, which involves pushing and rotating movements in the mass of accumulated material, does not differ from that of other hole-nesters.

Wallcreeper eggs are conspicuously large in relation to the adult's body weight and are oval, the shell moderately glossy and milky white with well-defined brown-red to black speckling, these markings often concentrated at the broad end. Fifteen eggs had average dimensions of 21.3×14.3 mm, the maximum size being 22.7×15.7 mm and the minimum 19.2×14.3 mm; the shell weight was 0.137 g. The full, fresh weights of eggs laid by

captives were, in order of laying, 2.52 g, 2.52 g, 2.49 g, 2.41 g and 2.40 g; in another case, the weights were 2.55 g, 2.45 g and 2.50 g. The normal clutch consists of three to five eggs, and is laid at a rate of one daily.

Incubation is undertaken by the female alone, beginning with the penultimate egg. She is fed regularly by the male, and she will leave the nest and hurry to meet him while shivering her wings; she will sometimes also raise her wings and flap them in the manner of a food-begging juvenile. Should the female leave the nest independently for a break from incubation and the male then arrive with food, the male will sometimes venture as far as the nest, searching for his mate. He will then fly off, but return again immediately, and this process can be repeated several times, the male still having the same food dangling from his bill. It is only when the female is absent for a long time that the male finally eats the food that he has been carrying.

On the first day of incubation, the distribution of incubation stints and time spent off the nest is very irregular. For example, at the nest of a wild pair, two incubation stints each lasted 55 minutes and two breaks from incubation each 53 minutes. Overall, the average length of incubation stints on the first day was 29.5 minutes, while that of periods spent away from the nest was 20.4 minutes. Periods spent on the nest lasted between 9 and 55 minutes, and breaks ranged from 4 to 48 minutes. During the course of incubation, this situation gradually balances itself out. Over the last days before hatching, bouts of incubation fluctuated between 7 minutes and 29 minutes, and the breaks ranged between 3 minutes and 9 minutes. During an observation period of six hours, incubation stints lasted on average 6.6 minutes and breaks 5.9 minutes.

The incubation period of the Wallcreeper, both in the wild and in captivity, is around 19 days, with a range of 18.5–20 days, which is exceptionally long for a bird of this size. Both parents care for the young, but only the female broods them; for as long as brooding continues, which was up to 14 days in the case of a captive pair, the male brings most of the food. In two years in Hauri's Swiss study, the female reared the brood alone when the male was lost, and Saniga recorded four similar cases in Slovakia, females coping alone in three, while the male fed the young alone in the fourth. Males, because they tend to forage farther from the nest, are thought more likely to fall prey to raptors. The male

This male **Wallcreeper** is returning to the nest-site, its bill packed with invertebrates for its well-grown nestling. This species places its nest within a crevice or cleft in a rock, on a cliff or, occasionally, on an artificial structure. Wallcreepers are probably monogamous as a rule, although polygyny has been recorded. The pair-bond lapses after breeding, but partners often meet up again on their breeding grounds the following spring. Such mate-fidelity appears to result from a high degree of site-fidelity; it is not unusual for pairs to use the same nest-site for several consecutive years. Even juveniles tend to gravitate back towards their natal territories.

usually feeds the young directly, but Hauri recorded a case in which a female frequently begged from her mate at the nest throughout the nestling period and then transferred the food to the young. The parents encourage the young to gape by giving the feeding-call (see Voice). Both sexes also keep the nest clean, dropping the nestlings' faecal sacs in flight or depositing them on a ledge at a reasonably long distance from the nest.

It would have been difficult to study the physical development of young Wallcreepers without the possibility of observing a captive brood. Newly hatched chicks have a covering of fluffy grey down on the head, scapulars and back. The gape-flanges are whitish and the mouth orange-yellow. Having opened to a narrow slit by day six, the eyes were fully open two days later. The sheaths of the innermost secondaries and of the body contour feathers opened on the twelfth day, and those of the primaries and rectrices opened when the young had reached 14 days of age. Apart from the area around the forehead, the rest of the plumage was already well developed. The young Wallcreepers had reached their maximum weight, over 23 g, at 19 days. That this was not just a factor associated with captivity was proved by the removing and weighing of a chick from a nest in the wild: it, too, weighed 23 g. This is above the weight of the adults, which is 17–19 g, but the weight of the young, on the day when they left the nest, had fallen to that of an adult Wallcreeper, and two days later it was 18 g.

From day 24, young at a site in the Ötz valley, in the Austrian Tyrol, which had been colour-ringed and were thus individually identifiable, left the nest to be fed, running towards the food-bearing parent. From day 25, they even emerged completely from the crevice in the rock. When sated, the young Wallcreepers went back into the nest and took up a position at the rear, the other brood-members having meanwhile moved to the front. Nestlings not receiving enough food would stay at the front. This carousel-like arrangement for feeding, which has been reported also for the hole-nesting Common Kingfisher (*Alcedo atthis*), was confirmed in studies of captive Wallcreepers. During an observation period of 3 hours 25 minutes, the colour-ringed young at the Ötz valley nest were fed 81 times: the "white-ring" chick received 24 feeds, the "red-ring" 20, the "yellow" 20, and the "green" 17 feeds. Bezzel noted the feeding rates at two nests in the Bavarian Alps, recording 30 morning visits, 14 of these by the male and six by the female, in 170 minutes at the first nest, and 14 morning visits by the male and six by the female, in 90 minutes at the second. At a nest with two young about 7 days old in Switzerland, 198 visits in 15 hours 25 minutes were by the male and 5 by the female. At the eastern extremity of the species' range, in Moravia, Bankovics made observations at a nest in the Hangayn mountains and recorded 14 feeding visits in 75 minutes, the male made 10 and the female 4. From observations by Saniga in Slovakia, the "working day" at the end of June may last for up to about 10 hours, with feeding visits between 03:30 and 20:30 hours.

Wallcreepers feeding young may range far from the nest and thus have to carry back the food over several hundred metres. To cope with this, a foraging individual will often gather several items together in its long bill. When it is gathering, the bird cannot, of course, take any food for itself. Consequently, adult Wallcreepers are frequently seen to be hastily picking up many items after they have made a feeding visit, but, as no larger item worth delivering to the nest is found, they start to bundle together food for the young. This gives rise to an uneven pattern of feeding visits, although the birds will, if there is a rich supply of food available close to the nest, change rapidly foraging at the latter site and carry each item separately to the offspring. For example, a male brought food eight times within 11 minutes and a female delivered food five times within 15 minutes.

Juvenile Wallcreepers are already unusually well developed at fledging. One day before they left, the Ötzal young were pecking at all manner of objects near the nest, and a prey item dropped during a feed was picked up and swallowed. In all cases observed by Löhrl, the fledging period was about 29, with a range of 28–30 days. Once they have left the nest, the young continue to be provisioned by both parents, each juvenile being fed until it is fully sated. They are probably independent some five or six days after fledging, although Saniga suggested a longer period of 7–

12 days. There is circumstantial evidence suggesting that the brood is divided, one parent caring for some of the chicks and the other attending to the rest, and the two partial-family groups may then move far apart. Even at this stage, however, juveniles will attempt to find food for themselves.

Captive young held temporarily in a box regularly gaped when the ventilation holes were blocked, which is the normal response to the darkening of the nest entrance that signals the arrival of a parent, but they adopted a "fright posture", with the bill pointed upwards, when the lid was removed in order to feed them. Wild nestlings will attempt to hide in the cavity or tunnel away from the nest when threatened, while fledglings in any surroundings spend much time hidden in a cleft or under a stone, and will use such a bolthole if danger of any kind presents itself. Adult Wallcreepers normally wing-flick and sing when in the presence of various predators, and they will also attack and chase Common Kestrels (see also Relationship with Man).

Wallcreepers are single-brooded, and doubt has to be cast on J. B. Baillly's claim, never confirmed, that early-breeding pairs in Savoie, in southern France, often laid again in early July, as such timing would involve problems with the completion of the adult moult and in finding sufficient food in a period of low night temperatures and often early snowfall. Compared with those bird species sharing the habitat, such as the Alpine Accentor and the Black Redstart, which are double-brooded, Wallcreepers require twice as long for a single breeding cycle. Baillly's report may have referred to late first clutches or replacement clutches, but even the latter have yet to be confirmed for wild Wallcreepers.

Data from central European countries illustrate the species' relatively high breeding success. In Switzerland, Wallcreepers bred successfully at Mitholz 14–15 times in 17 years; there was no breeding in years with long winters and much late snow. An average of 3.83 young fledged from 24 successful nests in Switzerland, and the corresponding figure for Slovakia, based on 36 nests and two pairs with fledged young, was 3.11. In a unique case in Vicenza, north-east Italy, in 2002, an unusually accessible Wallcreeper nest, close to the ground and in a wide, conspicuous fissure, was parasitized by a Common Cuckoo (*Cuculus canorus*). The adults repeatedly entered the nest, but re-emerged with the food, while the cuckoo chick, about nine days old, lay dead on the ground.

In Saniga's study in Slovakia, a wild female Wallcreeper was two years old in 1997 when she bred with her father, the age of which was unknown when he was ringed, in 1996. In addition, a two-year-old male, hatched in 1996, bred with his yearling sister in 1998 and also in the following two years. In captivity, female Wallcreepers have laid and attempted to breed at one year of age.

Movements

During the period 1982–2000, Saniga ringed a total of 46 Wallcreepers, 29 of them fledglings, in the Vel'ká and Malá Fatra mountains of central Slovakia. Of these 46, 26 were marked with individual combinations of colour rings. The colour-ringing enabled observations to be made which showed a high degree of site-fidelity of pairs to their breeding localities and natal philopatry (see Breeding). In Switzerland, an adult ringed at Chillon Castle in June 1947 was controlled there in July of the following year. Otherwise, very few Wallcreepers have been ringed, so that a summary of the species' movements must rely largely on visual observations.

This species is an altitudinal and, to some extent, a short-distance migrant, wintering mainly within the breeding range and adjoining areas. Some individuals, however, move up to several hundred kilometres from their nesting place and, in such cases, may even return to the previous year's wintering site, thereby surely disproving the idea, earlier proposed by Löhrl, that the species is not a migrant and that all long-distance movements are probably attributable to drift. In addition, there are a few observations of Wallcreepers on active migration. These include three in Bulgaria and one in the Ötz valley, in Austria, in March. Likewise, at Ulmethöchl, a migration watchpoint in the Swiss Jura, at least three and possibly five individuals migrated WSW singly and less than 50 m up in October 1967, and there are other Octo-

This female **Wallcreeper** is attending to the demands of a hungry fledgling. To attract its mother's attention, the youngster flicks its wings to reveal the stunning wing pattern. The typical clutch comprises 3–5 eggs, which the female incubates for 19 days. Both parents, particularly the male, feed the chicks during the nestling period, which lasts roughly four weeks. For the final four or five days before leaving the nest, the chicks develop sufficient confidence to venture to the nest entrance or even just outside. Once away from the nest, the young are fed by their parents for 5–12 days more before becoming independent.

Hüttenmoser]

ber reports for the eastern shore of Lake Constance and over the Thuner See, both also in Switzerland, and from the Chokpak Pass, in the western Tien Shan. Further, a Wallcreeper passing through at Heist, in Belgium, in November 1989 was seen shortly before a female of this species was discovered in Amsterdam, in the neighbouring country of the Netherlands (see Relationship with Man). Nevertheless, the possibility of occasional drift should not be excluded, bearing in mind that the Wallcreeper's mode of flight makes it extremely susceptible to this phenomenon. The species' spatial pattern of migratory behaviour most closely resembles that of the Water Pipit (*Anthus spinoletta*).

In the immediate post-breeding period, when families have broken up, many Wallcreepers first move to higher altitudes, adults before juveniles and ascending to up to 4500 m in Switzerland, for example. In Nepal, Diesselhorst found individuals at 3800–5000 m in September, and a juvenile is alleged to have been collected on 23rd July at about 6400 m in Ladakh, although doubt has been cast on the validity of this last report. In Slovakia in September–October, when there is typically fog up to 700–800 m, some Wallcreepers ascend above this, but move down again in the evening.

There are also winter records of this species at up to 2000 m, and even to 3200 m in Switzerland in February, and above 900 m in the coldest period, December–February, in Slovakia. Such individuals may be forced to come lower, commonly into valleys, by a lack of food. Most Wallcreepers, however, spend the winter months not within the narrower limits of the breeding area, but at lower levels. They are often seen in all months of the year on nesting cliffs at low and moderate altitudes and, although it is generally not clear whether the same individuals are involved, two ringed in central Slovakia in July did keep to the same territory throughout the year. Moreover, those remaining in the Slovakian mountains after breeding, up to about 25% of the population, tend to move only 4–15 km from the breeding site to the non-breeding locality.

Part of the Alpine population in south Europe probably spends the winter months in the southern and northern foreland of the Alps and in the Jura, but also farther afield. Wintering sites lie in all compass directions from the nesting sites, and the distance flown also varies considerably. Erratic movements may further confuse the picture. Regular wintering areas in France include the Vosges, the Jura, the Rhône valley, the Massif Central, and

westwards to the valleys of the Dordogne and Vézère. In Iberia, the species winters chiefly in lower parts of the breeding range, but also in the entire north-eastern quarter of the peninsula and on the Mediterranean coast south to Gibraltar; there have been occasional records in the Balearic Islands, although observations over the last 6–7 years suggest that the species is regular in Mallorca. The local population in Corsica descends to lower levels, and Wallcreepers are regular on cliffs of the west coast and at Cap Corse, these perhaps including individuals dispersing from Italy. They are regular in winter also on the coast of the former Yugoslavia, and in Cyprus, particularly in the Kyrenia range and on the south coast, where some remain for up to five months. The Wallcreeper occurs as a non-breeding visitor in small numbers in northern Iraq and Syria, and rarely, with variation between years, in Israel, mainly in the north. A recently fledged juvenile on Mt Hermon in June 1997 was probably from a local nest, which would represent the first breeding record for the area and a major range expansion to the south. Although there is no evidence that the Wallcreeper breeds in Lebanon, its regular occurrence at two sites in winter has been confirmed.

Remarkably, there were no fewer than ten records of vagrant Wallcreepers in Britain between 1792 and 1985. Other noteworthy occurrences are of individuals seen in Germany, north to Hamburg and Heligoland and east to Berlin; on Jersey; in southern Portugal; in Morocco and Algeria; on the Mediterranean islands of Malta, Sardinia and Sicily; and in Jordan, where two appeared in spring 1897. In addition, the species has been observed in a wide scatter of European towns and cities, as well as on the Black Sea coast of Romania, in Crimea and on the rocky coast of the Sea of Azov. Individuals wintering in Morocco would need to complete a journey, presumably from the Pyrenees, of some 960 km, while the sole record for Algeria, at Constantine, may have involved the crossing of 640 km of sea. It is possible that Wallcreepers breed in north-west Africa, but there is no proof.

A similar pattern of vertical displacement and winter wandering holds true for the eastern populations of the Wallcreeper in Kazakhstan and China, and in the Indian Subcontinent, where the subspecies *nepalensis* breeds mostly above 3300 m. In winter, it commonly reaches the foothills in suitable country and sometimes wanders considerable distances, up to 500 km, into the plains, in

the Indian Subcontinent reaching as far as such places as the Salt Range, Lahore, Ghazipur, Amritsar and Delhi. Nevertheless, there are winter records of Wallcreepers at elevations as high as 5000 m, and exceptionally 5730 m, in Nepal and 2895 m in Bhutan.

Winter site-fidelity was proved over two successive years, and likely over four, at a quarry in Rottenburg, in southern Germany, which is some 130 km from the nearest regular nesting places. A Wallcreeper was trapped and ringed there in the third successive year of the species' occurrence in the quarry, and this ringed individual then returned in the following year; after the last observation, no wintering Wallcreeper was present at the site for several years. Further indications of such fidelity over two years are provided through observations in Switzerland, in Belgium, in the Netherlands and, perhaps most astonishingly, at Cheddar, in southern England, where, in the 1970s, what was presumably the same male returned in winter to a quarry where it had spent the previous November–April period.

The timing of the autumn movement, apparently irrespective of the weather conditions, is regular and basically similar throughout the species' range, individuals occurring outside the breeding areas mostly from October to April. The birds disperse upwards from mid-July or late July to August, adults generally moving before the young. Hauri's study at Mitholz, in Switzerland, showed Wallcreepers to be rare in the breeding area from August to September, although they were frequently recorded at that time higher up the mountains. Similarly, and as mentioned at the start of this section, individuals have been recorded at high altitude in Nepal up to mid-September.

The main downslope movement takes place from late September or the beginning of October, independently of the onset of winter higher up, and most wintering sites are occupied by mid-November, arrival dates ranging from mid-September or October to November. At Rottenburg, the territory was first occupied between 20th and 30th October in five out of twelve winters. Captive individuals regularly displayed migratory restlessness in the first five days of October, and the subsequent aggression of pair-members meant that they had to be separated during the period from October to April.

Wallcreepers depart from their European winter territories in late February or March, occasionally not until April, and the breeding sites are generally reoccupied in April or May, but there are April records of individuals in Switzerland well above the breeding range, at 4500 m, for example. Arrival on the breeding grounds is not necessarily the same thing as arrival in the breeding locality; in the Ötz valley, in Austria, returning Wallcreepers apparently linger on south-facing cliffs near breeding sites until the snow has cleared, which usually happens in early May. In addition, heavy snowfall in spring may force the birds to descend to lower levels. For example, large numbers were noted in a village in the foothills of the Talasskiy Alatau mountains, in Kazakhstan, in early April. Many such individuals are in poor condition and some may perish. Stragglers occur exceptionally outside the breeding areas in May or even during the breeding season.

Relationship with Man

Birdwatchers speak of the Wallcreeper as being beautiful, flamboyant, near-mythical, completely unique, one of the most remarkable and spectacular birds in the world, and the spectacular nature of its habitat clearly adds to the fascination. In Switzerland, E. Hüttenmoser's wonderful photographs result from an impressive ability to scale cliffs and to get close to Wallcreepers in their breeding habitat, while vagrants turning up in more easily accessible places, such as the south coast of England or the Dutch city of Amsterdam, not surprisingly attract large numbers of admiring birdwatchers. Visits to regular wintering sites such as that described by H. Harrop and G. Jenkins in southern France are another possibility.

The Wallcreeper's large wings, with their exquisite pattern and rounded tips, and the bird's mode of flight evoke the Hoopoe or even a butterfly, and mountaineers who know the species indeed often refer to Wallcreepers as "butterfly-birds". How apt, then, that a Wallcreeper wintering at Rottenburg, the ringing of

which confirmed its winter site-fidelity (see Movements), should have been caught in a butterfly net. One of the Wallcreeper's Chinese names means "rock flower", and poetic names in German include *Fliegende Alpenrose* and *Fliegender Almrausch*, both of which allude to the pink-red blooms of the alprose or alpine rose (*Rhododendron ferrugineum*).

On a different note, Wallcreepers were said to inhabit old cemeteries and to nest in human skulls, and the French even called them *oiseaux des cimetières*, referring to just that thought. It was also said that the bird's startling carmine wing-coverts, which gave rise to the earlier scientific name of "*phoenicoptera*", had been "taken from the Cardinal's robes". Portrayed on the postage stamps of at least a dozen different countries, the Wallcreeper has given its generic name, *Tichodroma*, to the journal of the Slovak Ornithological Society/BirdLife Slovakia, founded in 1987, while the Italian Gruppo Piemontese di Studi Ornitologici "F.A. Bonelli" has an attractive Wallcreeper logo.

Wallcreepers are not well known generally. They often live in extreme and inaccessible habitats, but they can be difficult to watch and are easily overlooked, sometimes because of their rarity, even near busy tourist routes. In the Austrian Tyrol, Böhm, a biologist at the Alpenzoo, at Innsbruck, considers the species to be not especially rare, but she believes that rambles do not really use their eyes and thus seldom find a Wallcreeper of their own accord. If a wintering individual was seen on a church in Innsbruck in the winter, or in one of the gorges of the Inn valley in the summer, it was almost invariably taken to be an escaped exotic. Then, once most local people had got to know the species at the Alpenzoo, the number of reports of wild Wallcreepers increased.

Wallcreepers are frequently found in impressive mountain landscapes, but they have also bred or wintered on a number of remarkable buildings, too. J. Hornskov found a pair breeding in a crack in the wall of the Potala Palace, in the Tibetan capital, Lhasa, in 2007, and F. Ludlow often saw this species on the Potala and Chagpori, and in the neighbouring hills, in the summer. In its European breeding range, special nesting sites include the Neo-Romanesque, fairytale Neuschwanstein, the most famous of three castles built for the "mad" King Ludwig II of Bavaria (1845–1886), which also featured in the children's film "Chitty Chitty Bang Bang". Another is the Swiss Castle of Chillon, dating mostly from the late twelfth and thirteenth centuries, which is located near Montreux, on the eastern shore of Lake Geneva. It was the setting for Lord Byron's narrative poem "The Prisoner of Chillon", written in 1816, and Wallcreepers bred there in a castle room in three years in the 1940s. In the first year, the room was "in use", by military engineers, but not open to the public; the birds entered through a broken windowpane and their nest was at 5 m on a beam. Four young fledged in two of the three years, and the observer, A. Chatelanat, once moved two young back close to the nest to prevent their falling into the lake. No breeding has been recorded on buildings in Switzerland in recent years.

Outside the breeding season, Wallcreepers have been observed, most fittingly, on the Great Wall of China, and on a famous Moghul monument and World Heritage Site, Humayun's Tomb, in New Delhi, India. Wintering individuals have also graced such French architectural gems as Notre Dame Cathedral, in Paris, the Palace of Versailles and Chartres Cathedral. In Greece there are records at Delphi and the Acropolis of Athens, and in Hungary, where the Wallcreeper is a rare but annual passage and winter visitor, the widely scattered traditional sites include both the cathedral and the television tower in Pécs. A female wintering in Amsterdam, in the Netherlands, roosted behind pink neon letters high up on the Free University building, one of the tallest in the city.

A Wallcreeper that reached Finland in October 1941 would have been a notable record of vagrancy, but it turned out to have been an involuntary stowaway in an aircraft. It was found hiding in a wooden box with holes at one end, and it had probably gone to roost there in Silesia, in Poland, on the previous evening. During its stay of about a month at Pori airport, it climbed about on the walls of buildings.

So far as is known, only the Löhrls and one private aviculturist in the German town of Heidelberg have succeeded in breeding Wallcreepers in captivity. A single attempt at the Alpenzoo, in Austria, in 1965 failed. At St Gallen, in Switzer-

Wallcreepers go to considerable lengths to protect their broods from predators. An overhanging rock usually offers protection to the nest-cavity. The nest itself, a rough cup of damp moss and plant fibres, tends to be placed deep within the crevice, as far as 75 cm from the entrance. There are normally two access points, enabling the adults to enter and leave separately. A nest placed at the very entrance to a crevice is thus something of an exception to the rule.

land, Girtanner, a pioneer of Wallcreeper study, was the first to keep these birds, and it is astonishing that A. Brehm, who purchased several from Girtanner, had to pay 80 Marks for each of them well over 100 years ago. The old Berlin Aquarium "Unter den Linden", where Brehm was Director from 1869 to 1874, held a large collection of birds, as well as fishes and reptiles. All the animals, together with porcelain information plaques, among them an attractive one for the "Alpine Wallcreeper", were transferred to Leipzig Zoo when the Berlin Aquarium closed, in 1910. A Wallcreeper, alongside many other native animals, was on show to the public in the great State Exhibition at Innsbruck in 1893, and another was found exhausted on the glass roof of Innsbruck's only multi-storey building around 1930, but it survived for only a few days in the care of an amateur bird-fancier. E. H. Zollikofer, of Ellikon, in Switzerland, reared and exhibited Wallcreepers, and one of his birds was kept for two years and described and illustrated by the Heinroths. Zollikofer's birds several times built nests and laid, and in two cases the eggs hatched, but the young were ejected shortly after hatching.

The Löhrls first acquired a young male Wallcreeper for rearing in 1964. This bird lived in an aviary for five years and was imprinted on humans (see Breeding). Then, under licence from the State Government of Tyrol, in Innsbruck, two young were taken from each of two nests at different sites, Obergurgl and Vent, in July 1968. The rock-climbers were A. Aichhorn of Salzburg, a highly experienced and careful mountaineer of proven quality, and a climbing companion called Feuerstein. Aichhorn ringed a brood of Wallcreepers for Löhrl and was generally a great help, having an outstanding knowledge of Alpine birds. In the 1960s, he was working on his dissertation about White-winged Snowfinches (*Montifringilla nivalis*), but his fieldwork also gave him the opportunity to conduct extensive observations on breeding Wallcreepers, as both species were present in the same habitat.

At the first nest, on the Hohe-Mut-Bach, near Obergurgl, two young were already at the nest entrance, waiting to be fed, on 19th July. The fact that they went back into the hole after a feed and sometimes spontaneously so suggested that they would not fly off when disturbed, and this did, indeed, prove to be the case, although they were later judged to have been within a day or two of fledging. When the ropes were in place 2–3 m from the hole, the young remained inside. The male Wallcreeper was very agitated and, without bringing food, twice looked into the hole while preparations were under way for the descent. Although it looked

tiny from a distance, Löhrl had judged the size of the nest-hole correctly by observing how much space was left when one of the adults entered. Aichhorn was able to thrust his whole arm into the cavity up to the shoulder, and in fact needed to in order to reach the nest and young. The hole descended steeply, but without passages leading off to the side, so that the nestlings had nowhere to escape to.

The nest on the Ramolbach, at Vent, was in a long crevice and contained four young probably 5–6 days before fledging and thus still being fed in the nest. Following a familiar pattern, the male was extremely wary, but the female not at all so. When the climber was busy at the nest, both adults approached and flew past very close, the food-carrying female coming to within 2 m. She also gave the usual warning song (see Voice). This nest was suspended in the middle of a crevice about 1 m long, which became narrower but continued underneath the nest and evidently had many branches, so that it proved very difficult to extract just two of the four nestlings when they abandoned the nest.

It was again thanks to Aichhorn's climbing and other skills that the Alpenzoo, in Innsbruck, acquired some young Wallcreepers in 1962, thereby becoming the only zoo in the world to have the species in its collection. Extricating the young from a nest in a rock crevice about 80 cm long on the side of a gorge at Obergurgl was an extremely difficult undertaking. Two ladders, which had to be firmly anchored in the glacial stream running through the gorge, were used as a means of gaining access to the nest.

One female Wallcreeper was found stunned by the shock wave produced when a threatening avalanche was detonated as a precautionary measure in January. Brought to the Alpenzoo, she adapted to life there relatively easily and reached the impressive age of 14, while another bird, a male, was a good 12 years old, and neither of them showed any obvious signs of old age. Two males at the Alpenzoo in 2007 were then five years old.

In 1970, of the Löhrls' three surviving birds, the female from the Vent nest paired with the male from Obergurgl, laid five eggs and started to incubate, but she gave up the breeding attempt when she began to moult heavily. The same pair bred successfully in 1971, and the two young that survived were completely hand-reared and then released back into the aviary. Importantly, this successful breeding enabled Löhrl to present the first exact information on the incubation and nestling periods, and also on the development of young Wallcreepers, and in general to study the way in which the captive birds behaved towards each other

through the year, thus clarifying many aspects of the species' biology. In 1972, two breeding attempts by the same pair failed, but intensive observations of colour-ringed wild young were especially valuable. Some Wallcreepers were taken to the Alpenzoo in 1972, the last given to a bird-fancier in 1973, although a captive-bred female was acquired in that year, mainly for the purposes of studying the spring moult.

The low numbers and sparse distribution of the Wallcreeper, together with the fact that it is difficult to keep in captivity, have generally discouraged attempts to turn it into a bird for the cage or aviary. There were, however, rumours that the female wintering in Amsterdam from November 1989 to April 1990 and from November 1990 to April 1991 was one of a number that had escaped shortly before at Schiphol airport. In support of its view that the bird was of wild origin, the Dutch Rarities Committee emphasized that a Wallcreeper had flown past at Heist, in neighbouring Belgium, on 5th November 1989; the Amsterdam female had returned for a second winter; and there was no documentation for the alleged Schiphol birds. Large numbers of Plumbeous Water-redstarts (*Rhyacornis fuliginosa*), often labelled "Rotskruiper", the Dutch name for the Wallcreeper, are imported, whereas the Wallcreeper is unknown as a cagebird in the Netherlands and is never offered for sale in the trade.

In the 1960s, the Alpenzoo went to considerable expense, to the amount of what would today be the equivalent of about 4500 euros, to build an aviary of three sections where Wallcreepers could be kept, and seen by visitors, in conditions as close as possible to those of their natural habitat, thus fulfilling a long-held dream of former Director, H. Psenner. Hence, consideration had to be given, both by the Alpenzoo curators and Löhrl, to providing suitable rocky surfaces with crevices, in part planted, on which the birds could climb, constant running water for bathing, places for roosting, dusting and sunning, and to which to escape and, more generally, the possibility of separating the birds when they are at their most quarrelsome outside the breeding season (see Breeding). It is important also that Wallcreepers have sufficient room in which to fly about, and glass is not a problem since they quickly recognize it as an impenetrable barrier, while visitors to the Alpenzoo, admiring "rare" native birds with beautiful plumage, find it easier to take photographs.

While providing the correct conditions is important, so, too, is a suitable diet. Such items as crushed and dried insect "meal", hard-boiled egg yolk, mealworms and, rather successfully at the Alpenzoo, a mixture of quark (curd cheese) and finely minced ox heart have been offered to captive Wallcreepers, but Löhrl and the Alpenzoo staff recognized that it is essential to give the birds live insects and spiders, particularly during the moult, for their general wellbeing and in order to prevent the glorious carmine-red of the wing-coverts, derived from the carotenoid pigment astaxanthin, from fading to an unattractive grey-pink, as happened with the Heinroths' captive. Light traps have been used as a means of attracting all kinds of insects to the aviaries and, at dawn, these will hide in cracks and crevices, thus allowing the Wallcreepers to forage naturally by probing and extracting prey items as they move about on the rocks, which also helps to ensure that the bill does not grow too long.

At the Alpenzoo, the food provided is live insects, including crickets, adult and larval pyralid and other moths, ant pupae and the quark-meat mixture referred to above. Hand-rearing proved to be relatively uncomplicated when young Wallcreepers were given a mainly insect diet with calcium every 20 minutes during a day of 12–14 hours. Some insects, such as caddis flies (Trichoptera), certain tiger moths (Arctiidae) and foul-smelling bugs, were completely rejected by Löhrl's captive birds; the adults took blowflies (Calliphoridae), but never fed them to the young. They readily took earwigs, too, not bothering about the insect's threateningly raised pincers. When an eyed hawkmoth (*Smerinthus ocellata*) was attracted by the light and entered the aviary through the small-mesh wire netting, it was later discovered by the male Wallcreeper, which seized it and carried it to a stone for treatment (see Food and Feeding). The moth managed to free itself and save its life by opening its wings to reveal the blue-and-black "eyes" on a pink background, which caused the Wallcreeper to retreat in alarm and hop around it in a wide arc, not daring to touch it again.

Status and Conservation

Owing to its typically large territory and strict habitat requirements, the Wallcreeper breeds at low density over much of its range. It has a fragmented distribution in mountainous areas of central and southern Europe, which is less than half of its global breeding range. As it is exceedingly difficult to survey and census breeding Wallcreepers, much remains to be clarified about the species' status and distribution, particularly farther east.

There is little detailed and up-to-date information for southern parts of the former USSR. G. P. Dementiev and N. A. Gladkov's assessment of this species as rare in the Caucasus and Transcaucasia and in Turkmenistan, where A. K. Rustamov confirmed breeding only in the Kopet-Dag, is apparently supported by recent surveys, at least in Armenia and Azerbaijan, although there is a contrastingly rather high population estimate for the Russian north Caucasus (see below). In Kazakhstan, the Wallcreeper is restricted to the Tien Shan, where it has been described as relatively common in the Trans-Ili Alatau around Almaty, and the Saur Mountains, while another, more cautious assessment for the country was that it was a rare resident. Scant and old information suggested that it was a common breeder in Kyrgyzstan, and widespread but only locally common in Tajikistan. Both E. V. Kozlova and more recent German literature indicate that the Wallcreeper is common in the Gobian Altai of Mongolia.

Further summaries indicate that the Wallcreeper is locally common, especially in winter, in Afghanistan and the Himalayas, but somewhat scarce in southern Tibet, although C. Vaurie considered it widespread and abundant in that region. It is believed to be uncommon and sporadic in China, in the extreme west, the Qinghai-Xizang plateau, the Himalayas and some central and northern parts, while individuals visit much of the south and east of the country in the non-breeding season. Using subjective assessments of abundance, some authors considered the species to be a common resident in the north of Pakistan, including in winter throughout the Gilgit main valley, fairly common and widespread in winter in Nepal and fairly common but local in India, and a common winter visitor and possibly resident, though its status is not well known, in Bhutan.

The relatively small European breeding population, estimated at 38,000–100,000 breeding pairs in or around the year 2000, was adjudged stable in the period 1970–1990, and probably remained stable in most of its range in the following decade, although trends were not available for key populations in Spain, which held 9000–12,000 pairs, and France, with 4000–20,000 pairs, in that period. There was previously some uncertainty about the Wallcreeper's status in Corsica, but breeding, which is probably regular, was confirmed for the island in 1978, and the population is thought to number several tens of pairs; the first observation was in 1912, but the species may well have been present there for longer.

An earlier estimate for Europe, excluding Turkey, was of 14,000–20,000 pairs, more than 60% of which were in the Cantabrian Mountains and the adjacent Spanish Pyrenees. Also in the Pyrenees, there are 4–8 pairs in Andorra and, moving east through the Alps, an estimated 500–1000 breeding pairs are found in Switzerland, where the Wallcreeper is widespread in the Alps, 20–40 pairs in Liechtenstein and 700–1400 in Austria. It is considered to be not very rare in the Austrian Tyrol, where Wallcreepers can be found in every one of the "better" gorges. It is a rare but regular breeder in the north Bavarian Alps of Germany, with a population of 100–200 pairs, although earlier estimates were much lower. In the Jura, on the Switzerland-France border, 81 certain, probable or possible breeding sites were recorded between 1956 and 1994, and the estimated total population is 63–99 pairs. Italy, where Wallcreepers breed in the Apennines, is a stronghold, with 2000–6000 pairs. Small-scale fluctuations between years characterize the Alpine population, but no long-term changes are evident. Local population decreases and the desertion of traditional breeding areas in recent years in the Alps and Pre-Alps, and also in the Polish Carpathians, may be due to very wet conditions in spring and poor summer weather, which bring low breeding success, as well as difficulties for observers monitoring the species.

Whereas many Wallcreepers breed on steep rock faces that may be 1000 m or so high, some pairs nest on the rocky sides of gorges no more than 20 m high. Such dark and damp nest-sites are prevalent in the Himalayas, for example, where raging mountain streams liberally cover the nest-site in spray. Wallcreepers breeding alongside rivers often use the watercourse as foraging grounds. Particularly during rain, they search for small invertebrates such as chironomid midges that linger around the water surface.

Helmut Denzau]

Some 30–50 or possibly 60 pairs live in the Slovak Carpathians, while the species is a very rare and local breeder on the Polish side of the same mountains, most of the total of 15–20 pairs being in the High Tatra, where there may be some overlap with Slovakia. It is rare in the Czech Republic, occurring mainly in winter and in the east, with no proof of breeding, and in Ukraine there have been no breeding records for many years. Among a number of south-east European countries with Wallcreeper populations, Romania has 1200–1500 pairs, and the others include Bulgaria, with 250–400 pairs, Slovenia, with 200–300, Croatia, with 1–10, Serbia and Montenegro, with 45–60, Macedonia, with 50–100, Greece, which has 100–300 pairs, and Albania, with 10–100. The scattered breeding areas in Turkey are thought to hold between 5000 and 25,000 pairs. In the region of the Caucasus and Transcaucasia, some 15,000–30,000 pairs are estimated for Russia on the north side of the main Caucasus range; the species is known to breed in Georgia, but there are no population counts or estimates for that country, and it is considered rare in Armenia, with 150–200 pairs, and in Azerbaijan, with 100–1000 pairs.

Living in extreme, often inaccessible habitats, Wallcreepers are little threatened by humans. The species is listed as protected on Appendix III of the Bern Convention, and its European Threat Status is provisionally evaluated as “secure”. It is abundantly clear, however, from the cases cited by U. A. Corti for part of the Alpine population, that many were shot in the nineteenth century and the early part of the twentieth century for collections and as trophies, and also in order to find out what the birds were. Two days after one was shot near Krems, in Lower Austria, a boy was seen to be sporting one of the bird’s wings as a hat decoration. In Europe and, even more so, farther east, there is a general lack of data on population size and trends, and the number and distribution of nest-sites. Large-scale censuses are difficult because of the habitat inaccessibility already alluded to, and because the birds are often not so conspicuous as may be thought. In the Austrian Tyrol, one pair bred just a few metres above a regular hiking route through a gorge, but it was not disturbed by the walkers and the nest-site was finally lost to erosion. Wallcreepers wintering in towns and villages are generally not disturbed there, either.

Despite feeding exclusively on insects and other invertebrates, and generally not undertaking long-distance movements, the Wallcreeper manages to survive by producing a single brood of, in most cases, few young. This suggests that the mortality rate is very low, and Löhrl’s study certainly found nest losses to be ex-

remely rare. Predation, by mustelids and raptors such as the Eurasian Sparrowhawk, probably has an impact only on small isolated populations.

Hitherto, humans appear to have had little or no influence on Wallcreeper numbers. Nevertheless, being a habitat specialist, needing a varied range of invertebrates and having a small population restricted to the Bavarian Alps, the species is considered potentially threatened in Germany and has been placed on that country’s Red List. If various illegal and uncontrolled human leisure activities continue to increase strongly, then this conservation status may prove to be useful.

Freestyle rock-climbing has increased hugely in the Wallcreeper’s extremely vulnerable habitat in the Bavarian and Austrian Alps. The climbers can cause disturbance not only by their mere presence, but also by the senseless practice of meticulously cleaning cliffs through the removal of natural vegetation growing on ledges and through other interventions, for the benefit of the sport. This needs to be carefully monitored, as it represents a threat to traditional summer territories with their small number of suitable nest-sites, and to winter territories, too. For France, G. Rocamora and D. Yeatman-Berthelot considered that there were no particular threats to the species’ habitat, not even rock-climbing outside the breeding season, but above all the population status and trends are poorly known and more data on this and on the species’ distribution are needed. With this in mind, the hope has been expressed that amateur birdwatchers with a head for heights might be encouraged to conduct the necessary surveys, while mountaineers sympathetic to ornithology would probably be able to provide useful supplementary information. Global warming and the consequent “greenhouse effect” could be a serious longer-term threat in reducing the natural range and population of a high-mountain species.

Canyoning, known in America as canyoneering, involves travelling in canyons or gorges by using a variety of techniques. These can include walking, scrambling, climbing, jumping, abseiling and/or swimming, and newly established hiking routes through gorges, with specially erected ladders and artificial platforms, are quite likely to impinge on breeding Wallcreepers and may represent a serious cause of disturbance. Wallcreepers visit road cuttings in India, and have thus joined the list of birds that benefit from human activities. On the other hand, some observers have frequently seen them flitting away just ahead of a vehicle, so that it is quite possible that a few may be hit by cars or buses.

PLATE 5

PLATE 5

Family TICHODROMIDAE (WALLCREEPER) SPECIES ACCOUNTS

Genus *TICHODROMA* Illiger, 1811

Wallcreeper

Tichodroma muraria

French: Tichodrome échelette

German: Mauerläufer

Spanish: Treparriscos

Other common names: Red-winged Wallcreeper

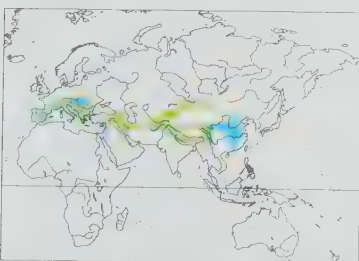

Taxonomy. *Certhia muraria* Linnaeus, 1766, southern Europe.

Sometimes treated in a subfamily of the nuthatch family (Sittidae), but differs distinctly in various morphological features and also in several aspects of behaviour. Geographical variation only slight; race *nepalensis* considered insufficiently differentiated by some authors, who treat species as monotypic. Other proposed races are *longirostra* (mountains of Iran) and *ognewi* (Tashkent, in Uzbekistan), synonymized with nominate and *nepalensis*, respectively. Two subspecies currently recognized.

Subspecies and Distribution.

T. m. muraria (Linnaeus, 1766) – breeds in mountains of S & E Europe (Spain and S France E, including Corsica, to Italy, Balkans, Caucasus, S & E Turkey) E to N & W Iran (Zagros Mts, Elburz Mts).

T. m. nepalensis Bonaparte, 1850 – mountains from Turkmenistan and E Iran (Kerman and Khorasan) E to Kazakhstan (Tien Shan), W Mongolia (Mongolian Altai, Gobi Altai) and, in S, to Himalayas and N. C & E China (N & E Tibetan Plateau E, discontinuously, to Hebei and W Liaoning, and to Yunnan).

Descriptive notes. 16.5–17 cm; 16.7–19.3 g (nominate), 13–20 g (*nepalensis*). Unmistakable in all plumages, but small, roughly the size of Eurasian Nuthatch (*Sitta europaea*); long (2.3–4.2 cm), thin, slightly decurved bill, and strikingly patterned large, broad, round-ended wings. Male nominate race breeding is medium grey above; lesser and median upperwing-coverts carmine-pink, also red-pink partially on alula, primary coverts and greater coverts, with inner greater coverts much duller; underwing-coverts and axillaries pale red-pink; flight-feathers dark grey with carmine-red bases of outer edges and sooty-black ends, two

white spots (small inner and large outer) on each of four long outer primaries (wing pattern striking in flight, also when wing-flicking at rest); tail black, tipped grey, white on outermost feathers; chin to breast black, extent rather variable, rest of underparts dusky grey; iris dark brown; bill and legs black. Female breeding is similar to male, but generally has lower throat to upper breast greyish-white with mottled black patch of variable size. Non-breeding plumage of both sexes is paler grey above, chin to breast whitish without dark throat patch. Juvenile is like non-breeding adult, but more uniformly grey, tinged brown on throat, with bill shorter and straighter. Race *nepalensis* has longer wing but shorter bill than nominate, on average larger white spots on wing and tail, is darker grey above and below, yellow-ochre or buff-brown tinge on head, more often tinged pink at base of tail. **VOICE.** Vocal all year. Song (in Europe) consists of ascending clear whistles with lower end note, latter either directly in same sequence or well separated from main strophe (or may be omitted, mainly at start or end of breeding season and during winter). In Himalayas (race *nepalensis*) song described as rich whistled notes, often gently rising or even level, followed by higher-pitched

but falling end note. Also short trills and warbles recorded. Both sexes sing, female mainly on winter territory. Contact calls whistled chirps, somewhat reminiscent of “tschirp” or “schilp” of Eurasian Tree Sparrow (*Passer montanus*); also described as repeated “pli, pli, pli” notes, and “tsche”, “chup” or “zui”, “tui” and “touiht”; similar calls uttered during feeding of nestlings and for signalling position of fledglings for feeding parents. No specific excitement or alarm calls recorded, probably owing to solitary way of life. Outside breeding period, song (given by both sexes) apparently serves mainly to advertise territory.

Habitat. Varied rocky regions, typically including steep, rugged cliffs and boulder-strewn slopes, and damp, shady gorges in mountains, with holes and crevices for nesting and roosting; rocks generally interspersed with grassy ledges, other vegetation including herbaceous plants, moss, shrubs and trees, and running water often present. Characteristic mix of sunlit and shaded areas important for foraging. Similar rocky habitats favoured in winter at lower levels include quarries and sea cliffs, also earth and clay banks and buildings, and recorded even in cities. Altitudinal range in Europe (e.g. in Switzerland) 350–3450 m; mostly 2300–3100 m in Turkey, and 2800–4000 m (majority probably at 3000–3500) in Tien Shan; largely above 3600 m in Himalayas (but down to 1500 m in winter), and recorded to 5100 m in Tibetan region.

Food and Feeding. Diet mainly small and some larger insects, including adults, larvae and eggs, also spiders (Araneae) and some other invertebrates. Recorded prey include damselflies (Odonata), stoneflies (Plecoptera), grasshoppers and crickets (Orthoptera), earwigs (Dermaptera), bugs (Hemiptera, including aphids), adult and larval Lepidoptera, dipteran flies (e.g. of families Tipulidae, Asilidae, Syrphidae and Muscidae), ants and bees (Hymenoptera), and beetles (of families Curculionidae, Carabidae, Scarabaeidae and others); spiders and harvestmen (Opiliones) important, but ticks (Acari), woodlice (Isopoda), centipedes (Chilopoda) and small molluscs (Gastropoda) also taken. Usually forages alone. Progresses mainly with short, jerky hops, sometimes with sidling, creeping and walking; on vertical surfaces sometimes makes upward leap accompanied by single rapid wingbeat. Takes prey from surface of rocks or among vegetation on ledges; also investigates holes and tunnels of various kinds, and extricates prey from cracks and crevices. Some prey taken in flight. Occasionally searches for food on ground, sometimes turning over leaf litter and small stones, using the closed bill for this purpose. Larger items usually carried to a large flattish stone or other flat area and beaten against substrate until dismembered.

Breeding. Season Apr/May–Jul/Aug in Europe, depending on altitude, and mainly May–Jul farther E, e.g. in Himalayas; single-brooded. Probably monogamous. Solitary and territorial breeder; home range often extensive, both horizontally and vertically. Nest of moss, plant fibres, rootlets and grass, with hair, wool and feathers densely matted together, sometimes as lining, for insulation, placed in cleft in rock (sometimes up to 80 cm inside hole), between or behind rocks or boulders, sometimes on or inside building. Clutch 3–5 eggs, pointed oval to pear-shaped, white with some small dark red to blackish spots, average dimensions 21.3 × 14.3 mm; incubation by female, period c. 19 days; chicks fed by both parents, male bringing most of food, nestlings come to nest entrance and even outside crevice at 24–25 days, nestling period c. 29 days; juveniles fed by parents for several days after leaving nest, probably independent c. 5–6 days after fledging, possibly not until 7–12 days after. Breeding success relatively high: average 3.83 young fledged from 24 successful nests in Switzerland, 3.11 from 36 nests (and two family parties) in Slovakia. Scant data suggest that some females first breed at 1 year, earliest for male 2 years.

Movements. Short-distance and altitudinal migrant throughout most of range. Most winter within or close to breeding range, some move up to several hundred km and may show fidelity to wintering site; extends to plains of N Indian Subcontinent, and fairly regular in non-breeding season in S & E parts of China; one winter record in extreme NE Myanmar. Following upslope dispersal after breeding, main autumn movement to lower levels late Sept or early Oct and arrival in winter quarters Oct–Nov; return from late Feb or Mar–Apr, although snow conditions may delay arrival at nesting locality. Has straggled to England, Channel Is (Jersey), N France and N Germany (including Heligoland and city centre of Berlin), Low Countries, Portugal, islands in Mediterranean, NW Africa (Morocco, Algeria), Iraq, Syria and Jordan.

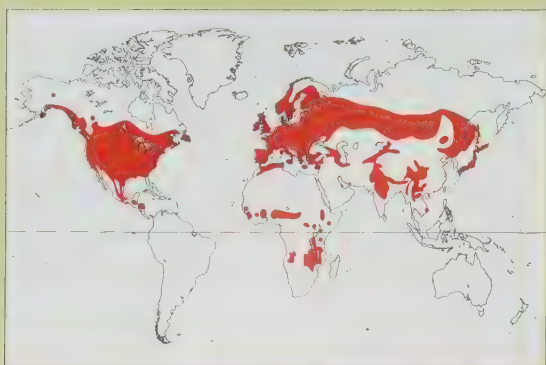

Status and Conservation. Not globally threatened. Locally fairly common. Because of its sparse distribution, often in inaccessible montane habitat, and elusive, inconspicuous nature, this species’ precise distribution, population and trends are not well known, particularly in E parts of range. In Europe 38,000–100,000 breeding pairs estimated, with key populations in France (4000–20,000), Spain (9000–12,000) and Italy (2000–6,000); farther E, 5000–25,000 pairs estimated for Turkey, 15,000–25,000 in Russian N Caucasus. European population considered stable during 1970–1990, probably also 1990–2000, thus provisionally evaluated as secure. Protected in most European countries, but listed as “critically endangered” in Poland, “vulnerable” in Liechtenstein and “near-threatened” in Slovakia; red-listed in Germany. Development of mountain regions and considerable increase in human leisure activities, especially rock-climbing, cause disturbance and threaten habitat in breeding and wintering areas.

Class AVES
Order PASSERIFORMES
Suborder OSCINES
Family CERTHIIDAE (TREECREEPERS)

- Small passerines with medium-long stiffened tail, short rounded wings, longish, slender, decurved bill, and intricately marked, highly cryptic plumage.
- 11–15 cm.

- Palearctic and Oriental Regions, one species in Nearctic and one in Afrotropics.
- Forest, woodland, parks and gardens.
- 2 genera, 10 species, 48 taxa.
- No species threatened; none extinct since 1600.

Systematics

The family Certhiidae comprises two genera. *Certhia* was established in 1758 and *Salpornis* in 1847. The various members of the genus *Certhia* are clearly very closely related to one another, and they form the subfamily Certhiinae. Indeed, so close are they in appearance that there was, until recently, general agreement among taxonomists that there were only five or six species. In recent years, however, the American representative of the genus, the American Treecreeper (*Certhia americana*), also commonly known as the “Brown Creeper”, has been generally afforded species status, and two additional “cryptic” species, Hodgson’s Treecreeper (*Certhia hodgsoni*) and the Manipurese Treecreeper (*Certhia manipurensis*), have been revealed. Furthermore, a totally new taxon has been discovered in south-central China, and this has been named as the Sichuan Treecreeper (*Certhia tianquanensis*). This was initially thought to be a species of the widespread Eurasian Treecreeper (*Certhia europaea*), but the two have been found to occur sympatrically without interbreeding. In addition, its morphology and vocalizations indicate that the Sichuan Treecreeper is a separate species. This is supported by genetic studies, which further suggest that the Rusty-flanked Treecreeper (*Certhia nipalensis*) is its closest relative.

The second genus, *Salpornis*, is monospecific. The single species, the Spotted Creeper (*Salpornis spilontus*), resembles the *Certhia* treecreepers in build and general coloration, and the genus has commonly been placed in the family Certhiidae. Nevertheless, it lacks the stiffened tail feathers characteristic of *Certhia* and, because of this, it has alternatively been treated as forming a subfamily of the nuthatches (Sittidae) or as a monospecific family, Salpornithinae. Data on DNA–DNA hybridization suggest, however, that *Salpornis* is the closest relative of *Certhia*, and it seems reasonable, therefore, to place it in the family, Salpornithinae, of Certhiidae. *Salpornis* is one of a small group of passerines that occur disjunctly in Africa and south Asia. The trend in recent times has been to separate these disjunct populations as distinct species, and this course of action could well be appropriate with *Salpornis*. Moreover, variation within *Salpornis* in Africa alone is such that one or more distinct species could be involved. At the time of writing, new results into the biometrics of selected morphological characters, some structure and sequences of cytochrome *b* is about to call for specific recognition of the African and the Asian populations. This study supports treatment of the Spotted Creeper as a separate

family, most closely but still loosely related to the Wallcreeper (Tichodromidae).

Certhia is well defined as a genus, but two questions have faced taxonomists. The first concerns which other, similar-looking genera should be placed with *Certhia* in the family Certhiidae, and the second is that of the relationships of this family, however defined, to other passerine genera.

Salpornis has been discussed above. In addition, owing to their outward similarities, at least on the museum bench, two other families were long associated with the Certhiidae. These are the rhabdornis (Rhabdornithidae), which are often referred to as the “Philippine creepers”, and the Australasian treecreepers (Climacteridae), sometimes called the “Australo-Papuan creepers”, which were either placed within Certhiidae or placed next to it in taxonomic sequence. Rhabdornithidae has long puzzled tax-

Subdivision of the
Certhiidae

[Figure: Ian Lewington]

The family Certhiidae takes its name from treecreepers of the genus *Certhia*. Treecreepers have a highly specialized niche, foraging for small invertebrates on tree trunks and branches, to which *Certhia* morphology is supremely adapted. Short legs enable the bird to stay close to the trunk, as illustrated by this **Bar-tailed Treecreeper**. Long toes and strong claws give it good grip, while the slender, decurved, fine-tipped bill is well suited to probing fissures in the bark.

[*Certhia himalayana yunnanensis*, Chengdu Botanical Garden, Sichuan, China. Photo: Dong Lei]

onomists. In terms of behaviour, diet and vocalizations, the poorly known rhabdornis are clearly not close to Certhiidae, but the most recent genetic evidence does, at least, place them in the same superfamily, Muscicapioidea. The Climacteridae, on the other hand, are members of an ancient radiation, the “basal Corvida” (see below), and seem not at all closely related to Certhiidae.

In a broader context, the certhiid treecreepers have always been closely associated with the nuthatches, and these two families had, in turn, been placed close to the tits (Paridae) and the long-tailed tits (Aegithalidae), despite differing in many aspects of structure, plumage and behaviour. Studies based on DNA–DNA hybridization have, however, indicated that the Certhiidae are close relatives of the gnatcatchers and gnatwrens (Poliophtilidae), the wrens (Troglodytidae) and the nuthatches. In 2006, K. A. Jönsson and J. Fjeldså reviewed 99 molecular-genetic studies in order to construct a tentative “supertree” of relationships among all passerine birds. In the new arrangement, the oscine passerines are divided into parvorders as the “Basal” and “Crown” Corvida and the Passerida. The Passerida is then divided into three superfamilies, Muscicapioidea, Passeroidea and Sylvioidea. There appears to be a general consensus among modern taxonomists on all these major branches. Jönsson and Fjeldså placed the Certhiidae, together with the Sittidae, the Poliophtilidae and the Troglodytidae, as a single clade within the superfamily Muscicapioidea, while the Paridae and the Aegithalidae are far removed in the superfamily Sylvioidea.

At the species level, a number of changes have been made over the decades, largely on the basis of the findings of molecular-genetic analyses. Thus, as intimated in the opening paragraph, the American Treecreeper and the southern Asian Hodgson’s Treecreeper have in the past been treated as subspecies of the widespread Eurasian Treecreeper, but both exhibit vocal and genetic differences from the latter and are, therefore, better considered two separate species. Most interestingly, recent genetic evidence, based on the cytochrome *b* gene, indicates that the American Treecreeper’s closest relative is, in fact, the Short-toed Treecreeper (*Certhia brachydactyla*). In the Himalayan region and South-east Asia, the Sikkim (*Certhia discolor*) and Manipur Treecreepers were formerly treated as one species, then usually called the “Brown-throated Treecreeper”, but they are now separated on the basis of vocal and genetic evidence. Some uncertainty remains, however, as individuals from Nagaland and western Manipur, in north-east India, are sometimes placed with the Manipur Treecreeper, but their plumage features indicate clearly that they belong with the Sikkim Treecreeper.

Climbing vertical tree trunks is no mean feat, but a specially adapted tail makes the task a good deal easier. The twelve tail feathers are noticeably rigid in *Certhia* species such as this **Sikkim Treecreeper**, and the tough central shaft extends beyond the feather tip. This enables the treecreeper to support itself on its tail tip as it ascends the tree, just like a woodpecker (Picidae). Other adaptations include short, rounded wings which befit birds that usually only need to fly short distances between trees.

[*Certhia discolor*, Gaoligongshan National Park, western Yunnan, China. Photo: Christian Artuso]

Intraspecific variation has led some taxonomists to suggest that several additional species should be recognized. Hodgson’s Treecreeper displays marked geographical variation. In particular, the ranges of the nominate race and the subspecies *mandellii* abut in the Himalayas of northern India, but there is no evidence of intergradation between them. As well as differing morphologically, these two taxa appear to differ genetically to a sufficient degree that each may merit species status. The third and final subspecies currently included within Hodgson’s Treecreeper, *khamensis*, is morphologically much more similar to *mandellii*, although it does seem to exhibit a significant, albeit smaller difference in cytochrome *b*. The Short-toed Treecreeper varies only slightly in size and coloration, and the variation appears to be clinal in pattern. Nevertheless, European and north African populations have been found to exhibit moderately well-marked genetic differences, in addition to some vocal differences, and it may well be that the north African taxon *mauritanica* represents a separate species. Further study may help to clarify the situation.

Finally, the Spotted Creeper, although revealing only relatively slight geographical variation in plumage, does exhibit distinct vocal differences. The differences in voice between, on the one hand, the Indian and West African individuals and, on the other, the southern African populations may be sufficiently great to justify treatment of these two groups as separate species. Again, however, more information is needed, for example on the vocal characters of Spotted Creepers in Ethiopia.

Morphological Aspects

Within the Certhiidae, the members of the genus *Certhia* form a well-characterized group of extremely homogenous species. The very specialized niche that the genus occupies, that of gleaning small invertebrates from the trunks and branches of trees (see Food and Feeding), appears to provide limited options for divergence.

The bill is very slender, laterally compressed, sharply pointed, of short to medium length, and slightly to distinctly decurved. It is clearly an adaptation for probing narrow gaps and crevices in bark and extracting small items of food. The nostrils are positioned near the base of the bill, free of feathers but protected by a membrane, and the rictal bristles are rudimentary. The tongue is long, narrow and horny, with some bristles at the tip. The legs are short, with fairly long toes and strong claws, the claw on the hind toe being particularly long, and the tarsus is distinctly scutellate.

At a quick glance, *Certhia* treecreepers might appear to be mainly rather dingy brown birds. Closer examination, however, reveals the subtle beauty of this genus, as exemplified here by the **Eurasian Treecreeper**.

The upperparts of all nine species are intricately patterned, with pale streaks, spots, tips and fringes, and contrasting dark bars and chevrons. The resulting combinations of browns, buffs, whites and silvers are remarkably similar across the genus, but slight differences are often important for distinguishing the various species. These upperpart patterns are highly cryptic, providing effective camouflage against the open tree trunk.

In contrast, the underparts are usually unmarked and pale, being noticeably white in the more northerly species, but usually darker in southern taxa.

The pale underparts are thought to play an important role in mate-attraction, being prominent during the male's display flight. Note the remarkably long hind toe, an adaptation to the treecreeper's lifestyle of vertical ascents.

Tree creeper wings are short and rounded, with nine secondaries and ten primaries, the outermost primary being significantly reduced. The flight of these species is undulating, rather weak, and usually over short distances only. The twelve tail feathers are stiffened, with robust shafts that project at the tips, and the bird uses its tail as a prop as it climbs, exactly in the manner of woodpeckers (Picidae). This limits its climbing options and, like woodpeckers, tree creepers are unable to move downwards head first on a tree. At first sight, tree creepers would appear to lack the extra-robust feet and legs of nuthatches and the appropriate musculature for clinging on with the feet alone, but this is not so, as they can forage along the underside of branches, where the stiffened tail cannot help them to overcome gravity. It may well be that it is simply a question of balance, and that the placement of the legs makes the whole bird top-heavy if it attempts to walk downwards.

The plumage of tree creepers is thick, long and soft, and beautifully and intricately marked. The upperparts are basically brown with numerous buff spots and streaks, as well as some darker and more blackish chevrons and bars, and all nine species have a paler supercilium, although this may be rather muted. Highly cryptic, the coloration of the upperparts provides excellent camouflage against the bark of a tree. The underparts are much plainer and paler, whitish in the species with a more northerly distribution, but tending to be browner in southern taxa. The pale underparts are noticeable during display-flights in courtship (see Breeding). In the genus *Certhia*, the male and the female are identical in plumage, and the juveniles differ very little from the adults, merely tending to have slightly duller, looser and "shabbier" plumage with a few fine dark scallops or spots on the underparts.

Adults undergo a complete post-breeding moult, but unlike all other passerines, which replace the tail feathers "centrifugally", from the centre outwards, tree creepers retain the central pair of rectrices until all the others have been replaced. This enables them to maintain the usefulness of the tail as a support throughout the moult, the moult strategy thus being similar to that used by woodpeckers. Juveniles have a partial moult into first-winter plumage, involving some wing-coverts and, for some species, also the tertials or the tail.

So homogenous are tree creepers in their appearance that they present a considerable identification challenge in places where two or more species occur together. In parts of Europe, for instance, the Eurasian Tree creeper and the Short-toed Tree creeper are extremely difficult to distinguish from each other, even in the hand, and their vocalizations (see Voice) are by far the most reliable identification feature. The tree creeper species found in the Himalayas and south China are more distinct, but they had been poorly treated in the identification literature until the 1990s and many historical data, if based on field observations, must therefore be treated with some scepticism.

The Spotted Creeper, which is placed in its own subfamily (see Systematics), differs from *Certhia* in one important respect. Its tail feathers are not stiffened and it therefore climbs without using its tail as a support, which is the reason why it has sometimes been treated as a subfamily of the nuthatches (see Systematics). Its mode of locomotion, however, resembles that of *Certhia*, and there are no reports of Spotted Creepers moving head first down a tree. In contrast to the difference in the tail feathers, *Salpornis* shares with *Certhia* intricately marked, dark upperparts and a pale supercilium, and it, too, has paler underparts, although these are rather heavily barred darker and have paler spots. As with *Certhia*, the bill is laterally compressed and distinctly decurved, with the nostrils near the base; there are no rictal bristles. The tongue is long, narrow and horny, and has about five bristles at the tip. The tarsus is thick and short, with transverse scales in front, and the foot is large, with rather long, spindly toes and long, sharp, strongly curved claws, the hind claw especially so. There are twelve tail feathers, nine secondaries and ten primaries. The outermost primary is significantly reduced, but the wings, unlike those of *Certhia*, are rather long and pointed.

Habitat

All members of the family Certhiidae are closely tied to forest or woodland, where they forage almost exclusively on the trunks and larger boughs of trees. Coniferous and broadleaf, evergreen

Apart from feeding as family parties for a few weeks at the end of the breeding season, tree creepers are not particularly sociable, at any rate by day. By night, however, there is far greater contact between conspecifics. At least three species of *Certhia* roost communally, including the Short-toed Tree creeper.

This species spends the night in sheltered spots on buildings or inside holes and fissures in trees; the tree creepers sometimes excavate such tree holes themselves. During particularly cold weather, up to 20 birds may share a roost, piling up on top of each other to maximize heat conservation.

[*Certhia brachydactyla*.

Images/CD-Gallery]

and deciduous, forests are utilized. Certhiids will, at least occasionally, forage on the ground or on fence posts, and in extreme circumstances, as when migrants or vagrants are grounded in unsuitable habitat, they will forage on rocks and walls, but they otherwise stick very closely to the behaviour indicated in their English and many other vernacular names.

The habitats of three species of *Certhia*, namely the Eurasian, Short-toed and American Treecreepers, are well documented, but those of the remainder, and of *Salpornis*, remain relatively poorly

known. From the available evidence, it is clear that the limiting factors for treecreepers are the availability of trees with suitable foraging micro-habitats, and the availability of suitable nest-sites. These are, in turn, determined by the age and structure of the forest, with tree-species composition a secondary factor. Old-growth forests are more likely to provide large trees with rugged, fissured bark sheltering an abundance of invertebrates, and standing dead wood with peeling bark for nest-sites, and these are therefore favoured. Given the availability of suitable trees, however, treecreepers are adaptable and will utilize more open parkland with scattered trees, as well as parks and large gardens in some urban and suburban areas, especially in winter or when treecreeper breeding populations are high. The Short-toed Treecreeper in central and southern Europe seems to be particularly well adapted to these more open habitats, and in Spain and Portugal, for example, it can be abundant in the *dehesa* landscape dominated by evergreen oak (*Quercus*) woodlands. The Spotted Creeper is similarly tied to woodland with mature trees, and again the structure of the trees themselves and that of the forest are more important than are the particular species present. Spotted Creepers are found in mature, open *Isoberlinia* woodland in West Africa and in structurally similar mature miombo (*Brachystegia*) woodland in the southern tropics, but, rather anomalously, they occur also in juniper (*Juniperus*) woodland in the Ethiopian Highlands.

Within the aforementioned tolerance limits, treecreepers will occupy any available woodland, but the presence of another member of the genus can have a severely limiting effect on their habitat choices. Competitive exclusion clearly operates in Europe. Here, the Eurasian Treecreeper has a preference for deciduous woodland in Britain, where it is the only *Certhia* species present, but in Continental Europe, in the face of competition from the Short-toed Treecreeper, it is generally confined to coniferous woodland at higher altitudes, presumably a more marginal habitat, its congener occupying the more favourable deciduous woodlands. The Eurasian Treecreeper undergoes a similar "ecological release" in European Russia, again in the absence of the Short-toed Treecreeper, showing a strong preference for mature broadleaf and mixed forest, rather than conifers.

This process is presumably taken a stage further in the Himalayas and western China, where up to four species of *Certhia* may be present, each tending to occupy a distinct altitudinal band and particular forest formations. Thus, in Nepal, the Sikkim Treecreeper is found at the lowest elevations, in subtropical forest at 2000–2700 m, followed by the Rusty-flanked Treecreeper in moist mixed and deciduous forest at around 2550–3660 m, the

Foraging strategy is very similar in all treecreepers. With its body parallel to the tree, the bird ascends in little hops, its feet moving upwards in tandem and the stiffened tail supporting the bird at all times except during the hop itself. The narrow, decurved bill is used to probe under bark and into crevices, and, as shown by this **Eurasian Treecreeper**, the long, horny tongue is then deftly deployed to extract prey items concealed within. Treecreepers forage principally on the main trunk and larger branches, though occasionally they will feed on the outer branches. Eurasian Treecreepers even sometimes forsake their arboreal habitat to forage opportunistically on other substrates, including human constructions such as walls and buildings, and even on the forest floor among fallen pine needles.

[*Certhia familiaris britannica*, near Ringwood, Hampshire, England. Photo: Mike Read]

Treecreepers are almost exclusively carnivorous. As a rule, they mainly take small arboreal invertebrates, such as ants and other insects, and larvae, as illustrated by this **Rusty-flanked Treecreeper**. In winter, the birds may supplement this diet with seeds and other vegetable matter and, for bold American Treecreepers (*Certhia americana*) residing close to human habitation, suet and nuts taken from garden bird feeders.

[*Certhia nipalensis*, Chungthang, north Sikkim, India. Photos: Gaurav Bhatnagar]

Certhia treecreepers have an almost ritualized foraging strategy. They fly to the very bottom of a tree, often just a few centimetres above the ground, whence they spiral upwards around the trunk. This **American Treecreeper** is at the start of its perusal of a conifer. It will spend most of its time on the lower trunk, where branches are fewer and crevices that potentially conceal insects are more numerous. When the treecreeper feels that it has scoured the tree adequately, it flies to the base of another nearby tree and starts the process afresh. Spending time on large, old trees appears to be the key to efficient treecreeper foraging since their bark holds higher densities of invertebrates than that of young trees.

[*Certhia americana*, Kings Canyon, California, USA. Photo: Andy & Gill Swash]

Bar-tailed Treecreeper (*Certhia himalayana*) in open forests and orchards at about 2900–3660 m, and finally Hodgson's Treecreeper in coniferous forest at 2800–4200 m. It should be noted that most altitudinal data are based upon sight records, which are certainly open to error, and that there are few confirmed breeding records, so that the altitudinal bands occupied may, in fact, be more narrowly circumscribed than these figures suggest. Altitudinal separation is clearly not complete, and within a given altitudinal zone the overlapping species differ slightly in terms of the forest formations that they favour, but even this distinction is not total and up to three species have been found on territory in the same area, with apparently no difference in habitat preference. In these cases, differing bill lengths may effect ecological separation, allowing the syntopic species to exploit different food sources. Moreover, in the Bar-tailed Treecreeper the sexes do not overlap in bill measurement, further reducing competition, and there is hardly any overlap in bill length between the sexes of Hodgson's Treecreeper.

Further study of habitat preferences would clearly be worthwhile, and may be particularly relevant for the Sichuan Treecreeper. This restricted-range species is considered globally Vulnerable (see Status and Conservation) and is apparently confined to a very specific habitat. It has been recorded only in open, old-growth stands of Emei fir (*Abies fabri*), itself a globally threatened species, with a dense bamboo understorey.

General Habits

These small, diurnal, arboreal passerines are often tame and, indeed, indifferent to humans, although they do have what is, to the birdwatcher, the annoying habit of moving to the side of the tree trunk that is invisible to the observer. In general, they are altogether inconspicuous and unassuming, neither the plumage nor the voice demanding attention in the way in which those of most tits or nuthatches do.

Certhiids are normally observed as singles or in twos, both during and outside the breeding season, although they may, on

rare occasions, form small groups. For the Eurasian Treecreeper it has been noted that, apparently, the pair-bond sometimes persists outside the breeding season or, in some regions, pairs may be established in the autumn.

At times, treecreepers may be more sociable. After fledging, young Eurasian Treecreepers form family parties in which the individuals remain together for about 14 days, although this is dependent on the occurrence of second clutches, the young sometimes being divided between the parents. American

As befits a genus inextricably linked with trees, *Certhia* treecreepers are arboreal breeders. Typically, they site their nest between the trunk of a tree and its flaking bark, the narrow gap between the two being just the right size. Alternatively, certhiids such as this **Short-toed Treecreeper** nest in a crevice such as an old woodpecker hole; the key is that the entrance is large enough for the occupants to squeeze through, but too small for potential predators. Sometimes treecreepers nest within building or wall cavities, in the bottom of a raptor nest, or within a drey of squirrels (*Sciuridae*). They will also use nestboxes that have been carefully designed and suitably located.

[*Certhia brachydactyla*, Dombasle-sur-Meurthe, Meurthe-et-Moselle, France. Photo: Frédéric Fève/Bios]

Treecreepers likewise form family parties for about three weeks after the young fledge, and they and Eurasian Treecreepers are sometimes seen in small single-species flocks when on migration (see Movements).

Communal roosting has been recorded for at least three species of *Certhia*, and for such small-bodied birds it may be important for overnight survival. Eurasian Treecreepers roost in a variety of crevices or behind bark flaps, and, where such trees are available, they will excavate suitable cavities in decayed stumps or dig hemispherical hollows in the soft bark of ornamental redwoods (*Cupressaceae*), including giant redwoods (*Sequoiadendron giganteum*), the latter colloquially known as wellingtonias. They also roost under ivy (*Hedera*) and sometimes in buildings. Both solitary and communal roosting are recorded for this species, the individuals either using separate holes in the same tree, or sleeping in close physical contact, huddled together in a hollow or in the open on a trunk. Up to 13 or 14 Eurasian Treecreepers have been found huddled together at a roost. Such huddling is probably regular for fledglings, otherwise occurring only on cold nights. Once the nest is completed, the female roosts in it at night, and juveniles return to the nest to roost for the first few nights after fledging. Short-toed Treecreepers may also roost communally, with up to 20 individuals together in a dense huddle in cold weather, usually on buildings, where they cling to the wall under the eaves in a star formation, and some individuals may be totally hidden. Otherwise, this species roosts in trees, choosing very similar sites to those used by Eurasian Treecreepers. Once the bond has been

formed, the pair-members will roost close together, but the female roosts in the nest from the onset of laying.

After fledging, family parties of exclusively juvenile American Treecreepers roost together in the open, usually on a tree trunk sheltered by other trees. They form a tight circle, all heads facing inwards, as with Short-toed Treecreepers, and they use a different site each night. In addition, up to eleven individuals have been recorded as roosting in a cavity of a beam in a barn, in April. Otherwise, this species appears often to be a solitary rooster, but in Colorado, during the winters of consecutive years, groups of two or three individuals have been observed to roost every night in a crack or scar in the bark of the same tree. In winter, American Treecreepers may roost on or even inside buildings. In New York, for example, two individuals roosted every night in the angle formed between a chimney and a roof, their bills pushed into the wood of the roof.

In the presence of avian predators, treecreepers adopt a concealment posture, in which the body is pressed flat to the tree, hiding the pale underparts, the head is lowered, with the bill directed upwards, and the wings may be widely spread. They may freeze for several minutes in this position, presumably relying on their cryptic coloration for protection. Young Eurasian Treecreepers have also been noted to freeze in an upright posture, like that adopted by a bittern (*Botaurus*), as an anti-predator response.

American and Eurasian Treecreepers have been recorded as sunning, in which they adopt a spread-eagle posture, with the wings and the tail feathers spread. In addition, water-bathing has

The only certhiid not housed within the genus *Certhia* differs significantly in terms of nest location and structure. Rather than breeding in a secluded hole, the **Spotted Creeper** nests in an open tree fork, usually 3–12 m above the ground. The Spotted Creeper relies on impressive camouflage to safeguard its brood from predators. The nest is deep and cup-shaped, constructed from stalks, rootlets and bark chips, bound with spider webs and caterpillar secretions. It is lined with egg sacs and plant down, and is covered with lichen. It is the combination of this lichen layer and the Spotted Creeper's dark and light patterned plumage that makes the nest so hard to spot. Differences have been found in clutch size and egg coloration between the Spotted Creeper populations of Africa and India, which may lend credence to the argument that more than one species is involved.

[*Salpornis spilonotus*
xylodromus,
Harare, Zimbabwe.
Photo: Peter Steyn/Ardea]

In contrast to other *Certhia* treecreepers for which data are available, the male **Short-toed Treecreeper** usually takes full responsibility for nest construction. He builds two or three nest foundations, then shows them to his partner, whereupon she chooses one for completion; the process can take an entire month. To provide the nest foundation, the male collects twigs, grass, bark and plant fibres, and weaves them together into an untidy, sprawling mass that fills the chosen cavity. The nest is then lined with softer material such as feathers, hair, moss and lichen. While the majority of Short-toed Treecreepers breed as monogamous pairs, usually raising two broods per season, polygyny has occasionally been recorded. Indeed, in one case, two females were discovered breeding side-by-side in the same nestbox, incubating eggs and feeding chicks within a few centimetres of each other.

been observed for the American Treecreeper, but anting has not been recorded for any member of the family. Other types of maintenance behaviour include preening and scratching. The Eurasian Treecreeper scratches its head by using the indirect method, whereby it raises one leg over the wing on the same side.

Voice

The songs and calls of *Certhia* and *Salpornis* are mostly rather high-pitched and inconspicuous. The first vocalizations are the begging calls given by nestlings, from the age of 9 days at the latest. Other calls apparently stem from the begging calls, and the song is comprised of these calls arranged into a specific sequence. Adults deliver a variety of notes for contact and in social contexts, but all vocalizations are relatively short and simple in structure.

The songs of *Certhia* fall into two distinct categories. That of the Eurasian, Hodgson's, American and Short-toed Treecreepers is relatively complex, comprising a variety of note types. The remaining five members of the genus, namely the Bar-tailed, Sichuan, Rusty-flanked, Sikkim and Manipur Treecreepers, have a song that is much simpler, being a more or less rapid repetition of similar notes to produce a rattle or trill. Whether simple or complex, the songs are stereotyped, varying little from place to place or among individuals. This would suggest that the song is innate, rather than being learnt, but song-learning is well documented for both the Eurasian and the Short-toed Treecreepers, and in the case of the latter species it probably takes place at 50–100 days of age. Attempts to teach Eurasian Treecreepers by using recorded songs were unsuccessful, yet individuals were able to learn songs from interactions, either visual or acoustic, with live males. As the studies by G. Thielcke demonstrated, social interactions between males are apparently a requirement for song-learning for all *Certhia* species.

As a complication, there is an intricate relationship between the Eurasian and Short-toed Treecreepers in Europe. In places where the two species are found together, what have become known as "mixed" singers regularly occur. In these instances, the Eurasian Treecreeper imitates the song of the Short-toed Treecreeper and vice versa, or, more frequently, part of one song is "dubbed" or mixed into the other. It was once thought that all mixed singers were Eurasian Treecreepers, but Short-toed Treecreepers, too, may become mixed singers, especially on the edge of their range; in general, the mixed singers in any given area should be the less numerous of the two species. Each species has learnt the "wrong" song from its neighbours, be they of the other species or existing mixed singers. The imitations are perfect, but, although Eurasian Treecreepers are the better mimics, only a few are able to produce the multiple song types of Short-toed Treecreepers.

Salpornis has similarly simple, high-pitched songs and calls, lending support to a close relationship with *Certhia* (see Systematics). Notably, however, it exhibits some geographical variation, eastern and southern African populations having a distinctly higher-pitched song than that of individuals in India and West Africa. This certainly suggests that more than one species is involved, but it is hard to conceive how Indian and West African Spotted Creepers could be more closely related to each other than either one is to the intervening East African population, unless those in East Africa were relatively recent arrivals from southern Africa.

Food and Feeding

All members of the genus *Certhia* appear to employ the same foraging techniques. They shuffle, mouse-like, on the trunks and larger boughs of trees, occasionally among the outer foliage, employing the fine bill to extract prey from cracks and crevices. The mode of progression as the bird climbs upwards is a hop, the feet moving together, with the legs held one on each side of the body, and the head and upper body directed upwards and towards the tree trunk, so that the head bobs after each hop. The tail serves

as a prop at all times, except for a moment during each hop or when foraging on limbs. The long, curved claws, long toes, short legs and long tail make *Certhia* species highly adapted to climbing in a head-up direction. Typically, treecreepers fly to the bottom of a tree, work upwards in jerky hops, spiralling around the trunk, and then fly to the bottom of another tree and repeat the process. Much less frequently, they may indulge in flycatching or hover-gleaning.

The diet of treecreepers appears to be similar for all species, although there is little relevant information on the Asian ones. The bulk of their food items comprises various small invertebrates, such as ants (Formicidae) and other insects and larvae, spiders (Araneae) and their eggs, and pseudoscorpions (Pseudoscorpiones), supplemented to a limited extent, especially in winter, with some small seeds and other vegetable matter. In the winter months, American Treecreepers will visit bird-feeders and take suet and seeds. Nestlings appear to be fed exclusively with insects. Food items are swallowed whole and immediately. There are no records of a certhiid using its feet to hold down prey items.

Inventories of prey items have been published for the European and American species, but these are probably little more than lists of what suitably sized prey happen to occur in their habitats. Should clear interspecific differences in diet be revealed, they are likely to reflect the shape and length of the bill and, hence, the precise foraging niche. Treecreepers select larger trees, which tend to have trunks with more deeply furrowed bark, resulting in higher densities of invertebrates. It has been hypothesized that they may be able to increase energy intake by foraging on one large tree, rather than on numerous small trees; in studies in the United States, for example, it was found that, in Douglas-fir (*Pseudotsuga*) forests in Washington, an American Treecreeper, in order to obtain the same number of spiders as are available on a single old-growth tree, would have to fly to 13 young trees or 3.3 mature trees. Similarly, standing dead wood may be favoured as a rich source of prey. Treecreepers prefer to forage on the lower parts of the trunk, where the bark is more furrowed and there are fewer branches.

Eurasian Treecreepers start the nest-building process by constructing a rough foundation from twigs, bark, lichen and grass. Both sexes share this task, which may take up to nine days. Subsequently, however, the female assumes sole responsibility for collecting and positioning softer materials to serve as a comfortable, cosy lining. She seeks out feathers, moss, animal hair, spider webs or wool, carrying what she finds to the nest cavity (the fissure below the bark flap at the top of the image). If the birds start breeding early enough, they may raise two broods, as is the case with about one-fifth of pairs; this is most frequent in the south and west of the species' range. Prior to formalizing their relationship, pair members determine their mutual suitability through ritualized courtship display flights. These start with one individual spiralling around a tree trunk, showing off its gleaming white underparts in the dingy forest surroundings. There follows a chase, the male pursuing the female up and down the tree. The process culminates in courtship feeding: the female flutters her wings and opens her gape as wide as a hungry fledgling, and the male responds by presenting her with a choice morsel that illustrates the richness of his home range.

[*Certhia familiaris britannica*, Hampshire, England. Photo: Mike Read]

As if courtship, nest-building, egg-laying, incubation and feeding nestlings were not demanding enough for avian parents, they must carry out such tasks without attracting the attention of predators. It is imperative for adults to arrive at and leave nest-sites as rapidly and silently as possible. This is feasible when the nest is hidden amidst foliage. A hole in a bare tree trunk is a different matter, however, so this **Sichuan Treecreeper** is making a speedy departure from its brood.

[*Certhia tianquanensis*,
Wawushan,
Sichuan, China.
Photos: Li liwei]

Treecreepers rarely, if ever, store food. An American Treecreeper was reported as caching small bits of sunflower seeds (*Helianthus*) in the bark of pines (*Pinus*), although retrieval of seeds was never observed.

In contrast to the *Certhia* treecreepers, the Spotted Creeper does not use its tail as a prop when foraging. In other respects, however, it is very similar to them, both in its diet and in its mode of foraging. It consumes insects and spiders, which it picks from the trunks and larger branches of trees. As with the treecreepers, it starts near the base of the trunk and works its way upwards, before moving to the base of the next tree. While climbing, it holds the tail away from the bark, in the manner more of a nuthatch, and it will also cling upside-down to branches.

Although they generally forage singly or in twos, treecreepers also frequently join mixed-species foraging flocks, together with tits, long-tailed tits, nuthatches, kinglets and firecrests (*Regulus*), Old World warblers (*Sylviidae*) and others. It is not clear whether individuals or pairs attach themselves to the flock as it moves through their winter territory or home range, leaving again as the flock moves on, or whether some treecreepers move with the flock, covering a much larger area or even becoming semi-nomadic.

Spotted Creepers, likewise, may form small flocks in winter in India, and in Africa they often join mixed-species foraging parties. Up to ten Spotted Creepers have been recorded in such flocks in Zimbabwe.

Breeding

Whereas information on the breeding behaviour and biology of the three north-temperate species of treecreeper is relatively good or almost complete, comparable data for the southern Asian species is very poor or non-existent. In the nineteenth and early twentieth centuries, the finding of nests and eggs was a favourite pastime for naturalists, but they seem to have been largely defeated by *Certhia* in the Himalayas; of the little information that there is from there, much comes from unreliable sources or is clouded by doubts over the birds' identification. Similarly, in the Americas, the first nest of the American Treecreeper was not discovered until as late as 1879. The breeding habits of the Spotted Creeper in Africa and India are moderately well known.

In broad terms, the breeding season of the Certhiidae in the Northern Hemisphere extends from about April to June or July. It can begin a little earlier, in March, in the western Palearctic Region and in Mexico, and in southern parts of Asia nesting starts in January or February in some areas. The Spotted Creeper breeds

in February–May in India, while in Africa its season begins in January in Ghana but not until August or September in countries south of the equator. In the southern tropics in Africa, this species often has two seasons; in southern DR Congo, for instance, it breeds in August–October and again in February–March.

Certhia species are territorial during the breeding season. The breeding pair occupies a home range, and the area around the nest is apparently defended as a nesting territory by the male, usually with song. During territory establishment, males sing frequently, both while stationary and while climbing, with the bill held wide open; they may change songposts at brief intervals. Intraspecific competition during the breeding season usually involves threat calls, and song-duels at close quarters on or near the territory boundaries, as well as chases and aerial fights. Once

The **American Treecreeper** usually lays five to six eggs, although as many as nine. As in other congeners, the female takes sole responsibility for incubating the clutch, the male feeding her during the 13–17 days that this lasts. After hatching, the chicks are brooded by the female, but fed by both parents, for 13–20 days until they fledge. Thereafter, the fledglings remain dependent on their parents for as much as a further 17 days, or possibly more.

[*Certhia americana*

the territory has been established, the male sings more briefly, from lower on tree trunks, while foraging. The amount of time spent in singing is probably proportional to the number of conspecifics in the immediate area. The Eurasian Treecreeper is perhaps more territorial than is the Short-toed Treecreeper. Territories of the latter have poorly defined and poorly defended boundaries and may overlap, and in certain areas they may overlap also with those of Eurasian Treecreepers, with little or no conflict between the two species. In addition, Eurasian Treecreepers that are mixed singers (see Voice) will defend the territory against both conspecifics and Short-toed Treecreepers.

Courtship rituals, both of Eurasian Treecreepers and of American Treecreepers, involve special display-flights. In these, the treecreeper spirals rapidly around a tree trunk, first descending and then flying upwards, with the white underparts made conspicuous. Partners also indulge in excited chases, the male in close pursuit of the female, in spirals up and down the trunks. After chases, one or both individuals may raise the wings and flutter them rapidly, this being followed by further chasing or by courtship feeding. Courtship feeding, which starts during the nest-building stage and continues until the eggs hatch, usually takes place outside the nest; the female wing-flutters and gapes like a begging juvenile, whereupon the male lands above her, turns sideways, and places the food in the female's throat.

The typical site for a treecreeper nest is the space between the trunk of a tree and a flap of loose bark, usually dead or dying, the opening generally being just large enough for the treecreeper to enter. Nests may be close to ground level or high in a tree, up

to 18 m above ground, presumably depending on the location of available sites, but they tend to be recorded from the lower part of this height range. Where such sites are not available, treecreepers may be forced to be more adventurous in the placement of the nest, and they will then utilize other cavities, such as knotholes and abandoned woodpecker excavations. In addition, Eurasian Treecreeper nests have been found on or in buildings or stone walls, occasionally hidden among or behind vegetation, especially ivy, in masses of dead leaves accumulated in trees, and, very rarely, on the ground. Similar alternatives, as well as the base of a raptor's nest or a squirrel (Sciuridae) drey, have been noted for Short-toed Treecreepers, and the American Treecreeper can add woodpecker holes in fence posts, the spaces behind loose wooden tiles on buildings and the hollow beneath a piece of tin on an outhouse roof. Of the south Asian species, reasonable data are available only for the Bar-tailed Treecreeper; this uses similar sites to those described above, but it has been noted also as building in the angle between the trunk and a branch and in crevices among exposed roots. All three northern treecreeper species will make use of specially designed nestboxes or artificial nest-flaps.

For the nest itself, Eurasian and Short-toed Treecreepers first build a foundation of coarse material, such as twigs, conifer needles, bark fibres, grass, moss, lichen and wood chips, this often being a large and untidy basic structure, filling the cavity. They then line this with finer material, such as feathers, hair, wool, spider webs, eggs and cocoons, and soft moss and lichen. The American Treecreeper constructs a similar nest, although the foundation

With broods of five to seven nestlings to feed, on average, adult **Short-toed Treecreepers** have their work cut out during the breeding season. Both sexes must forage actively during daylight hours to bring back sufficient numbers of insects and spiders to satisfy their young. The male probably does the bulk of the provisioning, as the female also has brooding responsibilities. The nestling period lasts 15–18 days, after which the fledglings are thought to disperse relatively quickly. Their parents, however, are caught in a race against time. Trying to cram two broods into the summer, the male may leave the female to feed the first brood by herself while he builds the foundation of a new nest. When the chicks are 10–12 days old, the pair members swap roles, the male feeding the chicks while the female puts the finishing touches to the nest. In particularly efficient pairs, the female may even lay a second clutch before her first brood have fledged.

[*Certhia brachydactyla dorotheae*, Troodos Mts, Cyprus. Photo: Michael Gore]

of twigs, bark chips and the like is often crescent-shaped, with the ends higher than the hammock-like base, this supporting a cup of finer bark shreds, fibres, moss and plant down, sometimes supplemented with hair or feathers. The division of labour in the task of nest-building appears to vary among the species. In the case of the Eurasian Treecreeper, both sexes build the base but only the female adds the lining, and both sexes of the Bar-tailed Treecreeper build the nest. With the Short-toed Treecreeper, however, the male usually builds two or three foundations and the female selects one for completion, while it is the female of the American Treecreeper that builds, although the male may bring materials to the site.

All species of *Certhia* for which the relevant information is available lay eggs that are white, finely but variably marked with shades of reddish-brown, the markings frequently concentrated at the broader end, where they often form a ring or cap. With average dimensions of 15.5×12.1 mm, the eggs of the westernmost subspecies *britannica* of the Eurasian Treecreeper are typical in size. The American, Eurasian and Short-toed Treecreepers have a clutch size normally of five or six eggs; although clutches of up to nine eggs have been recorded for all three, one may speculate that these are the result of more than one female having laid in the same nest. The Bar-tailed Treecreeper, similarly, lays 4–6 eggs, but smaller clutches, containing an average of around 3–5 eggs, have been recorded for Eurasian Treecreepers in Japan and, as would be expected, a clutch size of 3–4 is recorded for the southernmost species, the Manipur Treecreeper.

For all species for which the data exist, only the female incubates; she is fed on the nest by the male. Incubation appears to

begin after the last egg is laid, and it lasts for around 15 days. Upon hatching, the nestlings are altricial, being mostly naked and helpless, with the eyes closed. Those of the American Treecreeper, for example, are entirely naked except for long, dark grey down on the head arranged in rows above both eyes and across the occipital region. Nestling treecreepers are fed by both sexes, although brooded only by the female. They leave the nest after 14–21 days and remain more or less dependent on the parents for 11–17 days afterwards.

Approximately 20% of Eurasian Treecreeper pairs are double-brooded, especially in the south and west of the range. Temporal overlap between broods is not unusual, the male building a new nest and the female even laying the second clutch while still feeding the first brood. Serial polygyny has occasionally been recorded for this species; in such cases, the male mates with a second female and feeds her young, rather than, or in addition to, provisioning the young of the primary female. Short-toed Treecreepers are usually double-brooded, and again there may be overlap in timing, the male starting a new nest while the female is still feeding the first-brood chicks. When the nestlings are 10–12 days old, the male takes over the duty of feeding them while the female completes the second nest; she sometimes lays the second clutch before the young from the first brood have fledged. Short-toed Treecreepers appear to be occasionally polygynous, and simultaneous bigamy has been recorded. In one case, two females of this species were found to be incubating eggs and feeding young at the same time in the same nestbox. In contrast, the American Treecreeper is single-brooded, but it will

This adult Short-toed Treecreeper appears to have reached the stage in the breeding cycle where its duties overlap, as it returns to the nest-site its bill crammed with both nesting material and insect larvae. Individuals may have to combine provisioning responsibilities towards a first brood with the establishment of a new nest-site in which to house a second brood. In more northerly latitudes, however, the norm is for pairs to raise just a single brood each year, probably because the breeding season is perforce more limited, with suitable conditions prevailing over a shorter period of time.

Ardea]

American Treecreepers, however, individuals breeding in more northerly areas move southwards in winter. With Eurasian Treecreepers, numbers involved and distances covered vary in an irregular pattern, although this species is possibly only a summer visitor in the northernmost parts of its range, implying regular movements there. Post-breeding dispersal takes place in the period from mid-September to mid-November, some being in a northward direction, with return movements between mid-March and early May. There is an old record of about 60 Eurasian Treecreepers being seen together on migration.

The American Treecreeper is perhaps a more regular migrant. Although some remain all year as far north as southern Alaska and southern Canada, there is a partial withdrawal from the north of the range and from higher altitudes; some northern breeders winter irregularly south throughout the eastern United States to Florida, the Gulf Coast, Texas and Arizona, and in northern Mexico. Migrants penetrate south of the breeding range from late August onwards, the main passage period extending from September to mid-November. Return passage northwards takes place between March and mid-May, most individuals having left southern areas by the early to middle part of April. The migration of the American Treecreeper is reported as being both nocturnal and diurnal, but the species is apparently very reluctant to undertake water crossings. On passage, this species sometimes occurs in small, loose monospecific flocks, rarely of up to 30 individuals.

The habits of certhiids in southern Asia are less well known, but all of the species are partial altitudinal migrants, moving downslope in the winter months. This post-breeding descent and pre-breeding ascent are perhaps made only in direct response to weather conditions, but the Bar-tailed Treecreeper is an exception, as it regularly disperses from its Himalayan and Central Asian breeding grounds to the plains of northern Pakistan and northern India.

Salpornis, the Spotted Creeper, is resident, although presumably undertaking some post-breeding dispersal. In Africa, however, this species is so poorly known that it is not clear whether records of supposed vagrants represent genuine wanderers or merely dispersal from undocumented local breeding populations.

lay replacement clutches after loss of the first one, and the general pattern may be that *Certhia* taxa breeding in more boreal habitats at higher latitudes or altitudes are single-brooded, as the period of time available for breeding is short, while those in more temperate environments are double-brooded. There is so little information on the southern Asian species that it is not clear how they fit into this pattern, but the Bar-tailed Treecreeper, which breeds in open coniferous forest and edge at medium and high elevations, is reported to be single-brooded.

The Spotted Creeper differs little from the *Certhia* species in breeding biology, but with three important exceptions, those of nest-site, nest structure and egg colour. It places its nest in the open, in a tree fork, rather than in a concealed cavity site, although there is an echo of this in accounts for the Bar-tailed Treecreeper indicating that the latter occasionally uses more open nest-sites. The nest itself is a neat cup, superbly camouflaged and extremely hard to find. Rather than being white, the eggs of Spotted Creepers in India have a ground colour of pale grey or greenish-grey and those of African populations a pale turquoise-blue, bluish-green or pale green ground, in both cases with grey or lavender undermarkings and brownish speckles and spots. Measuring about 19×13 mm on average, they are a little larger than the eggs of *Certhia*. The clutch size of the Spotted Creeper is comparatively small, at 1–3 eggs.

Movements

Where climate allows, treecreepers are rather strictly resident. Thus, for most Eurasian Treecreepers ringed in Britain, recoveries involve movements of less than 20 km and, for the Short-toed Treecreeper, a species the entire range of which lies within the temperate zone, there are few ringing recoveries beyond 10 km from the original site. In the case of both the Eurasian and the

The early days of the life of a juvenile Eurasian Treecreeper follow a pattern similar to that of its congeners. Nestlings are fed by both of their parents for their first 15–17 days on average before fledging, although this period may stretch to 23 days if they are being fed solely by the female because the male is busily constructing a new nest in preparation for a second breeding attempt. Once fledged, the young treecreepers continue to be fed by one or more parents for the first week, at which point they begin to test out their own foraging skills. After a further week, the juveniles are independent and join mixed-species feeding flocks moving through and beyond their parents' home range. Adult Eurasian Treecreepers are predominantly monogamous, although there is evidence of serial polygyny, some males mating with two females and seeking to raise two broods.

[*Certhia familiaris macrodactyla*, Lombardy, Italy. Photo: Pierandrea Brichetti]

The buff tips to the greater coverts, the scaled effect on the throat and upper breast, the short tail and short bill with a pale gape line age this Spotted Creeper as a young juvenile. Despite this species being widespread and better known than some of the Asian treecreepers, no data exist on the duration of incubation, nesting or fledging periods. What is known, however, is that only females incubate the eggs, but that both parents brood and feed the chicks. When this juvenile Spotted Creeper is fully independent, it may join congeners for the non-breeding season, or even team up with wide-ranging mixed-species foraging flocks.

[*Salpornis spilonotus emini*, Ngaoundaba, Cameroon. Photo: Ketil Knudsen]

As they are dependent on forest and woodland, and forage most effectively in old-growth forests, all certhiids are potentially at risk from anthropogenic deforestation. To date, however, no species is globally threatened with extinction. The **Sichuan Treecreeper** is Near-threatened, with fewer than 1000 birds estimated to remain within a range of under 20,000 km² in south-central China, where there has already been extensive deforestation. Even within this relatively small area, the species appears to be restricted to old-growth Emei fir forest in a narrow altitudinal band of 2500–2800 m. The only significant subpopulation occurs on the table mountain of Wawu Shan, a site now under pressure from tourism. This combination of restricted range, low population and new threats suggests that the species might perhaps require reclassification as threatened.

Relationship with Man

No relevant information.

Status and Conservation

Of the ten members of the family, none is considered to be globally threatened. The least secure is the Sichuan Treecreeper, which is listed as Near-threatened; indeed, until recently it was classed as Vulnerable. It has a very small theoretical population based upon a hypothetical range of 19,690 km², within which considerable deforestation has taken place. The Sichuan Treecreeper appears to be a relict species, and so far as is known it breeds only in open stands of old-growth Emei fir at elevations of about 2500–2800 m. Even at these high levels, intensive logging of primary conifer forests in the twentieth century considerably reduced the amount of suitable habitat available to this species. The only significant population known is on Wawu Shan, where forest covers the plateau at the top of a table mountain, the steep slopes of which, combined with an absence of roads, have to date made access by loggers impractical. Worryingly, however, the area has recently been opened up for tourism and development by the construction of a cable-car railway. The global population of the Sichuan Treecreeper is estimated at fewer than 1000 individuals.

All certhiid species are dependent on forest, with optimal conditions for all species likely to be old-growth forest with abundant large trees and standing dead wood. Throughout the ranges of all of the family's species, such forests have declined sharply in extent in historical times, and certhiid populations must be significantly smaller than the habitat's carrying capacity was before the arrival of modern man. In addition, there have been substantial reductions in forest cover in the Americas over the last

200 years, and in the Himalayas and western China even more recently. Both *Certhia* and *Salpornis* are hard to locate and observe, and in Asia and Africa are very poorly known, so that any marked downward trends in their populations would probably go undetected.

More insidiously, habitat fragmentation and degradation have diminished the suitability of the remaining forests for certhiids and many other species. Such forestry practices as thinning, selective felling and the removal of standing dead wood all have the effect of reducing the suitability of the habitat. In western North America, as an example, immature and mature second-growth forests, even 100-year-old stands, often do not provide the appropriate structural characteristics for American Treecreepers and are less suitable habitats for this species than are old-growth forests.

Certhia species are vulnerable to the effects of adverse weather. In Britain, for instance, the Eurasian Treecreeper suffers significant winter mortality when wet snow or rain is followed by hard frosts, resulting in trees becoming glazed with ice, which the birds cannot penetrate. Such conditions are much more likely where the trees are scattered than when they are part of a dense, closed-canopy forest, again suggesting that the former is a suboptimal habitat.

General Bibliography

(from mid-Aug in "irruption" years), with return movements mid-Mar to early May; local resident populations tend to mask presence of such migrants, but wanderers of N nominate race have reached e.g. Britain, Netherlands, Denmark, W Germany, SE Russia (including Saratov), Caspian Sea and Sea of Azov. Apparently reluctant to undertake water crossings, however, and little evidence of immigration in Britain apart from few records of vagrant nominate race; vagrants recorded Balearic Is (Mallorca), Channel Is and Faeroe Is. Also some post-breeding dispersal in N direction, and has reached Russian Lapland and White Sea. In E of range, recorded in winter in outliers of Greater Khingan Range in Mongolia, and an uncommon passage migrant and winter visitor in Korea; in NE China away from breeding areas, a few occur at Beidaihe (coastal Hebei) in late autumn and recorded Feb–Mar in Qingdao (Shandong). In addition, upland populations may undertake some altitudinal movements, e.g. in Japan, Tien Shan, W Ukraine, Caucasus and Hungary. **Status and Conservation.** Not globally threatened. Fairly common in general, but unobtrusive; uncommon to rare in many areas towards N & S extremes. Densities much lower in N of range than in S, e.g. 0.04–0.5 pairs/10 ha in Finland compared with 0.25–3.43 pairs/10 ha in Germany and 1.6–8 pairs/10 ha in Corsica. European populations either stable or exhibiting declines as a result of habitat fragmentation and loss of older-growth woodland. Susceptible to effects of hard winters, especially extended periods of glazed frost or freezing rain; N & E populations tend to fluctuate in irregular pattern, possibly tied to variations in crop of spruce seeds. **Bibliography.** Adamian & Klem (1999), Aho (1997), Aho *et al.* (1997), Brazil (1991), Cheng Tsohsin (1987), Cramp & Perrins (1993), Dementiev *et al.* (1954a, 1970), Enemar (1997), Enemar & Nilsson (2008), Etchécopar & Hùe (1983), du Feu (2002), Gorman (1996), Hafler (1993d), Hagemeijer & Blair (1997), Handrinos & Akriotis (1997), Harrap & Quinn (1996), Hirschfeld (1984), Jouard (1930b), Kren (2000), Martens & Geduldig (1988), Martens & Tietze (2006), Matsuoika (2007), McCarthy (2006), Mead (1975), Morioka (1994), Müller (2001), Norberg (1979), Osiejuk (1998), Osiejuk & Kuczyński (2000), Patrikeev (2004), Portenko & Stübs (1977), Raja *et al.* (1999), Rogacheva (1992), Roselaar (1995), Schickendanz (1978), Schönfeld (2003, 2006b), Sora (1997), Stepanyan (2003), Stresmann (1919a), Suhonen & Kuitunen (1991), Sultana & Khan (2000), Suorsa & Hakkarainen (2007), Suorsa, Helle, Huhta *et al.* (2003), Suorsa, Helle, Koivunen *et al.* (2004), Thibault & Bonaccorsi (1999), Thielcke (1961, 1962, 1986), Tietze (2007), Tietze *et al.* (2006), Tomek (2002), Vaurie (1957, 1959).

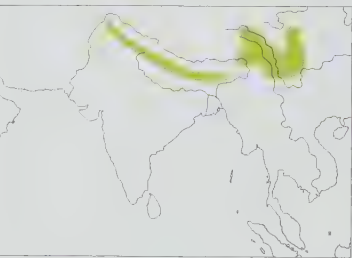

2. Hodgson’s Treecreeper
Certhia hodgsoni

French: Grimpereau de Hodgson German: Kaschmirbaumläufer Spanish: Agateador de Hodgson

Taxonomy. *Certhia familiaris hodgsoni* W. E. Brooks, 1871, Kashmir. Formerly treated as conspecific with *C. familiaris*, but differs genetically and vocally. Geographical variation marked: nominate race and *mandellii*, as well as differing morphologically, exhibit significant genetic differences (based on studies of cytochrome *b*), and their ranges abut in Himalayas of N India with no evidence of intergradation; they may each merit species status. Races *mandellii* and *khamensis* are much more similar to each other morphologically, but show significant, albeit smaller, difference in cytochrome *b*. Birds from the Kwanhsien region of Sichuan (China) having dull grey underparts described as race *kwanhsienensis*, which possibly worthy of recognition. Three subspecies currently recognized.

Subspecies and Distribution.

C. h. hodgsoni W. E. Brooks, 1871 – W Himalayas in Pakistan (Hazara, Indus Kohistan and Gilgit), Kashmir and NW India (E to Lahul, in Himachal Pradesh).
C. h. mandellii W. E. Brooks, 1874 – C Himalayas of N India from Himachal Pradesh (E from Kulu) E, including Nepal and Bhutan, to extreme W Arunachal Pradesh (Tawang).
C. h. khamensis Bianchi, 1903 – S China from S Gansu (S flanks of Qin Ling) S to S & SE Xizang, W Sichuan and Yunnan (Lijiang range and Nu Shan), and presumably NE India (in Pachakshiri region of Arunachal Pradesh); one Jun record from NE Myanmar (Adung valley).

Descriptive notes. 11–12 cm; 7.6–12 g. Nominate race in fresh plumage has crown and nape dull brown, feathers fringed black with narrow whitish shaft streaks, lores blackish, long white supercilium from base of upper mandible to nape (may be indistinct over lores); cheek and ear-coverts mottled black, white and rufous-brown; mantle and scapulars as crown but with large whitish feather centres (imparting spotted appearance), back, rump and uppertail-coverts cinnamon-orange with vague paler shaft streaks; upperwing-coverts dark brown, lessers with broad rufous-buff centres and darker tips, medians tipped whitish and broadly fringed rufous-buff, greater broadly tipped off-white on outer web and fringed rufous-buff at base (may have fine white shaft streaks); alula dark brown, broadly tipped off-white, primary coverts dark brown, tipped buff on outer web; inner webs of tertials pale grey-brown, outer webs brown, becoming black towards tip, fringed and broadly tipped pale buff; primaries and secondaries medium brown, all of these except outer three primaries with broad buff band across feather (only on outer web on P4, primaries numbered ascendently), bordered on each side by black-brown band, fringed pale buff distally of these bands and broadly tipped off-white (fringes and tips less distinct on outer primaries); tail feathers pale brown, darker adjacent to shaft, shafts pale buff; side of neck to throat and underparts off-white, washed dull buff on rear flanks, belly and vent, undertail-coverts pale buff, tipped white; in worn plumage (from about spring onwards) dark feather fringes above abraded, pale streaks on crown and nape better defined, and upperparts slightly colder; iris brown; upper mandible horn-brown, lower mandible pinkish-flesh; legs horn-brown. Distinguished from *C. familiaris* mainly by duller, less rufous upperside, from *C. himalayana* by plain unbarred tail, and from *C. discolor* by white throat and breast; from more similar *C. nipalensis* mainly by rather uniformly pale underparts lacking extensive and contrasting cinnamon on flanks and vent. Sexes similar. Juvenile is as adult but shorter-billed, duller overall, with underparts indistinctly and finely spotted darker. Race *mandellii* is darker and more rufous than nominate, upperpart feathers sooty black with smaller, darker and more richly coloured cinnamon-buff centres (thus appearing less spotted), supercilium tinged buff, rump rather darker and richer cinnamon-orange, and lower underparts darker buff; *khamensis* is poorly marked, similar to previous but on average slightly paler above, with paler and less rufous feather centres (especially on lower mantle and scapulars), rear flanks, vent and undertail-coverts slightly colder and greyer. VOICE. Calls include "tsree" note, sometimes doubled, and "tsree-seee tsree-seee". Song 2–3 high-pitched, sibilant "tsree" notes followed by several rapidly falling notes and then a terminal flourish that is usually lower-pitched, similar in basic structure to song of *C. familiaris* although a little shorter; little geographical variation, although song of nominate race perhaps on average shorter and less complex.

Habitat. Breeds in high-altitude coniferous woodland, often with mixture of rhododendrons (*Rhododendron*), birch (*Betula*) or occasionally oak (*Quercus*), sometimes in pure birch forest. In winter may descend into mixed oak–rhododendron woodland. In Pakistan found in summer above 3000 m; in Kashmir and NW India, from 3000 m to at least 3660 m, descending in autumn and winter to 2135 m, and in Uttarakhand Pradesh (N India) recorded at 2590–3960 m; in Nepal 2800–4200 m and recorded in winter at 2000–3800 m; in Sikkim and Darjeeling generally at 2440–3660 m, sometimes to 4115 m, and in winter down to c. 1675 m; in Bhutan 1800–4000 m (sometimes 1600–4200 m) in summer and mostly below 3200 m in winter; in Myanmar recorded at 3960 m in Jun. In China, found in SE Xizang at 2925–4115 m in summer, down to 2285 m in winter, in Sichuan breeds c. 2900–3960 m, moving down to 1600 m in winter (although at 2440–3050 m throughout winter at Wolong), and in Yunnan recorded from 2745 m to at least 3660 m and in winter still found above 3050 m.

Food and Feeding. Food small arthropods. Forages on trees in typical treecreeper manner, work upwards in jerky hops, spiralling around trunk, then flies to bottom of another tree and repeats process; recorded as foraging also on moss-covered rocks. Will join mixed-species flocks.

Breeding. Poorly known; few nests found, and older data in the literature unreliable owing to nomenclatural confusion and possibility of misidentification. One nest found on 4th May, in Nepal, had bottom lined with rhododendron bark, above this pieces of rotten wood, feathers and hair, was 50 cm above ground in hole in rhododendron; clutch 4 eggs.

Movement. Resident, but some altitudinal movements.

Status and Conservation. Not globally threatened. In Himalayas, rare and erratic in Pakistan and apparently very rare in Kashmir, but not uncommon from Uttarakhand E to Bhutan. The commonest treecreeper in SE Xizang, but rather uncommon in adjacent parts of China. In Pakistan, report of breeding in Murree Hills considered dubious.

Bibliography. Ali & Ripley (1983), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1983), Etchécopar & Hùe (1983), Harrap & Quinn (1996), Martens & Eck (1995), Martens & Tietze (2006), Rasmussen & Anderton (2005b), Roberts (1992), Robson (2000b), Spierenburg (2005), Tietze (2007), Vaurie (1957, 1959).

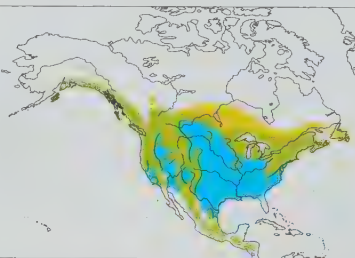

3. American Treecreeper
Certhia americana

French: Grimpereau brun German: Andenbaumläufer Spanish: Agateador Americano
Other common names: American Creeper, Brown Creeper

Taxonomy. *Certhia americana* Bonaparte, 1838, eastern and northern parts of North America. Formerly treated as conspecific with *C. familiaris*, but differs genetically and vocally; recent genetic evidence (cytochrome *b*) indicates that its closest relative is *C. brachydactyla*. Geographical variation slight and largely clinal, races intergrading where they meet, e.g. those breeding NE USA E from about SE Minnesota and S to N Virginia and Maryland are intermediate between nominate race and *nigrescens* (for convenience, included within former); on other hand, marked difference between N birds and Mexican ones. "Brown morph" of nominate race in Newfoundland described as a separate race (*anticostiensis*). In S Mexico, proposed races *jalisensis* (described from S Jalisco), *guerrerensis* (from Guerrero) and *molinensis* (from Oaxaca) all synonymized with *alticola*. Thirteen subspecies recognized.

Subspecies and Distribution.

C. a. alascensis Webster, 1886 – SC Alaska (S at least from Mt McKinley and E from Kodiak I); non-breeding also WC USA (Idaho S to SE Arizona and SW New Mexico, E to NW Arkansas).
C. a. occidentalis Ridgway, 1882 – Pacific coast from SE Alaska S in W USA to NC California, E to coastal slopes of Coast Range in Alaska and British Columbia and W slope of Cascades in Washington and Oregon; non-breeding also occasionally E to CS British Columbia and in WC California.
C. a. stewarti Webster, 1886 – Queen Charlotte Is (possibly also N Vancouver I), off British Columbia.
C. a. zelotes Osgood, 1901 – E slope of Cascades from S Oregon S through Sierra Nevada to mountains of N, E & S California and E to Nevada; non-breeding also Arizona and New Mexico.
C. a. phillipsi Unitt & Rea, 1997 – outer Coast Ranges of C California (from San Francisco S to San Luis Obispo County).
C. a. montana Ridgway, 1882 – breeds interior SW Canada (E from E flanks of Coast Range in British Columbia, N Alberta) and in WC USA from Cascades of Washington and C Oregon E to CN Idaho, NW Montana and W South Dakota and S to S Arizona and extreme W Texas (Guadalupe Mts); non-breeding also W to Pacific coast, E to Wisconsin and Louisiana, and S to N Mexico (N Coahuila).
C. a. leucosticta van Rossem, 1931 – mountains of S Nevada and WC Utah.
C. a. americana Bonaparte, 1838 – breeds S Canada from C Saskatchewan and C & S Manitoba E to S Quebec (including Anticosti I and Brion I), New Brunswick, Nova Scotia, Newfoundland and Prince Edward I, also NE USA S to Wisconsin, NE Ohio, E West Virginia and N Virginia; non-breeding mainly USA (E from Colorado, S to Texas and Florida) and NE Mexico (S to SE Coahuila).
C. a. nigrescens Burleigh, 1935 – Great Smoky Mts (E Tennessee and North Carolina), in E USA.
C. a. albescens Berlepsch, 1888 – mountains of SW USA (SE Arizona and SW New Mexico) and NW Mexico (S in Sierra Madre Occidental to NE Nayarit, NW Jalisco and W Zacatecas).
C. a. alticola G. S. Miller, 1895 – Mexico in Sierra Madre Oriental (S from Coahuila, W Nuevo Leon and Tamaulipas) and Sierra Madre del Sur (Jalisco E to Oaxaca).
C. a. pernix Griscom, 1935 – S Mexico (C Chiapas) E to Guatemala (to Volcán de Fuego).
C. a. extima W. deW. Miller & Griscom, 1925 – E Guatemala (Sierra de las Minas), Honduras and NC Nicaragua (S at least to San Rafael del Norte).

Descriptive notes. 12–13.5 cm; 8–9.9 g, autumn migrants in E USA (New Jersey) 6.5–9.8 g. Many races occur in two morphs, one basically brown (commonest in Maritime Provinces, and dominant in Newfoundland) and the other greyer. Nominat race in fresh plumage (autumn) has crown and nape medium brown, feathers with whitish shaft streaks and darker brown fringes, lores and upper ear-coverts dark brown, cheek and lower ear-coverts mottled pale grey and dark brown, supercilium off-white (buffy in brown morph); mantle and scapulars similar to crown but centres light grey and much larger, with darker fringes relatively small (brown morph has feathers of mantle and scapulars warmer, more gingerly brown, with reduced dark brown fringes); back, rump and uppertail-coverts cinnamon-orange, faint whiter shaft streaks and whiter feather bases; lesser upperwing-coverts brown-buff with large white centres and

darker fringes, median and greater coverts dark brown, medians with pale buff shaft and tip, greater with outer web tipped and fringed off-white (fringes broader and whiter on inner feathers); alula dark brown, tipped whitish, primary coverts dark brown with fine pale buff-white tip on outer webs; tertials light grey-brown, outer webs becoming dark brown towards tip, broadly tipped and fringed off-white on distal half; primaries and secondaries medium to dark brown (primaries slightly paler at extreme base), all of these except outer four primaries with broad buff-white band across feather near base, broad buff-white slot subterminally on outer web and small white tip on outer web; tail medium grey-brown, feathers darker along shaft, shafts buffy; side of neck off-white, throat and underparts white, breast washed pale grey, flanks, belly, vent and thighs washed pale drab buff, undertail-coverts washed buff and tipped white; in worn plumage (Apr–Aug) darker fringes and, especially, tips of upperpart feathers abraded and pale centres reach tips, producing more streaked (less spotted) effect, underparts slightly duller; iris brown; bill black to dark grey, basal part of lower mandible dull pale yellow or pale flesh; legs dark brown to flesh. Sexes similar. Juvenile is as adult but relatively buffer, with larger buff spots on upperparts (especially noticeable on crown), faint dark spotting on throat and scaling on breast, sometimes buffy fringes on upperwing-coverts. Races vary rather little, nominate bill relatively short and wing relatively long, upperparts moderately brown to greyish-brown (virtually dimorphic in upperpart coloration): *nigrescens* has upperparts rustier than nominate, pale streaks more brown-tinged than in other races (except Middle American and Pacific coast ones); *montana* is essentially dimorphic, grey morph has whitish supercilium, white streaks on crown sparse and narrow, brown morph slightly darker than dark-morph nominate, with reduced reddish-brown tones, pale streaks better defined and greyer, rump duller, reduced buff on flanks, rarely slight buff wash on breast, undertail-coverts dull pale buff to buffy grey (rarely, more orange-buff, this colour extending to flanks), bill long; *alascensis* is paler and greyer above than previous, with white streaks broader and more numerous, especially on crown, bill shorter; *occidentalis* has upperparts rather buffer and browner than *montana*, especially the pale streaks (although slightly darker than brown-morph nominate), also much browner than previous, and bill longer, breast washed buff, undertail-coverts orange-buff and this usually extending to flanks; *stewarti* resembles last, but upperparts brighter orange (most orange of all races); *zelotes* has upperparts browner than *montana* and darker, duller and more reddish-brown (less orange-brown) than *occidentalis*, streaks pale smoke-grey, rump duller dark reddish-tawny, may be slightly washed buff on breast, orange-buff on undertail-coverts and often extending to flanks; *leucosticta* is whitest below of all races; *phillipsi* has chin white, underparts greyish-brown, crown narrowly streaked deep buff, back streaked whitish (shafts and at tips of feathers) and smoke-grey, rump golden-cinnamon; *albescens* is very dark above with well-defined narrow whitish streaks (blackest dorsally of all races, with streaks whitest), very contrasting rump (darker and more chestnut than in N races), breast and belly light grey with slight drab wash, undertail-coverts light drab buff; *alticola* is as previous, but upperparts browner (less black), pale streaks washed drab olive, rump paler, more orange and less rufous, underparts less grey, more drab or buffy, especially undertail-coverts; *pernigra* differs from previous in having upperparts darker brown with narrower and more cinnamon-brown pale streaks; *extima* is as last, but crown and upperparts slightly less brownish, more black, with slightly broader and whiter streaks, rump darker (more rufous, less orange), underparts paler and purer grey, bill longer. VOICE. Calls include soft but penetrating, high-pitched, drawn-out, sibilant “seee” or “trsee”, a pure, tinkling or bell-like “ti” or “tyt” and an incisive “tsit”, sometimes repeated; flight call a brief “chip” or “sit”; fledged juvenile gives high, sibilant “tssssi” or “ts-tssi” location call, and when begging “chee”. Song, by male only, from prominent songpost in early spring, more sporadically once territories established, ceasing once young fledged, a short, weak warble (audible to 120 m) comprising 4–8 thin, high-pitched and sometimes sibilant whistled notes, often introduced by “tsree”, e.g. “tsce-tuti-sedu-wee” or “tsce-trrrr-sit-tu-tee” (or in California “tsce, sisi’suisi”), phrase 1–2 seconds in average duration, and repeated several times; each male gives stereotyped song, although some variation, with odd notes (especially terminal note) dropped or units slurred, and some birds string together standard phrase two or three times to make very long song. Also some geographical variation, with distinct regional dialects, in California “N song” is introduced with buzzing note while “S songs” terminate in a buzz (and isolated population on Angel I, in San Francisco Bay, gives song of simpler structure but greater individual variability).

Habitat. Primarily late successional stages of coniferous or mixed woodland, preferring extensive areas of mature old-growth, especially dense, well-shaded stands with abundance of large dead or dying trees for nesting and large live trees for foraging. In boreal zone of Canada and Rocky Mts typically in coniferous forest with mixture of aspen (*Populus*) and birch (*Betula*); farther S and at lower altitudes in NE USA and on W coast will use deciduous forest, favouring riparian woodland and wet areas such as forested floodplains, swamps and bogs, often with large dead trees, while in SW USA often in ponderosa pine (*Pinus ponderosa*). In Mexico and Central America breeds in moister stands of pine-oak (*Pinus-Quercus*) and pine-oak-fir (*Pinus-Quercus-Abies*) forests, but in Oaxaca (at least) absent from drier pine-oak stands. In autumn and winter found in wider variety of wooded habitats, more regularly including deciduous woodland, also riparian cottonwoods (*Populus*), scrub, well-wooded suburban areas, woodlots, parks and cemeteries. Altitudinal ranges generally follow conifer forest zones. In N and on Pacific coast breeds from sea-level to tree-line, e.g. to 2070 m in Washington, to 2440 m (sometimes 3050 m) in California, at least 2745 m in Idaho, to 3500 m in Colorado; in S mainly at higher altitudes, e.g. in North Carolina at 1370 m, in E Tennessee generally above 1200 m, in SW Texas 2440–2590 m, in Arizona 1980 m, in New Mexico 2135–3355 m (dispersing upwards to 3660 m); in Mexico occurs at 1525–3050 m in Chihuahua, above 1525 m in Sinaloa, to 3960 m in Jalisco, 1900–3000 m or higher in Oaxaca, and from at least 2225 m to 3900 m in Chiapas; 1550–3350 m in Guatemala.

Food and Feeding. Variety of small (less than 3 mm) insects and larvae, spiders (Araneae) and their eggs, and pseudoscorpions (Pseudoscorpiones); in winter may take small amount of seeds and other vegetable matter, and will visit bird-feeders for chopped peanuts, seeds and suet. Nestling diet appears to be solely insects. Forages mouse-like almost exclusively on trunks and larger branches of trees and stubs, delicately picking items from cracks and crevices in bark with its fine bill. Usual method of progression is to work upwards in jerky hops, spiralling around trunk, and then fly to bottom of another tree and repeat the process. Rarely feeds on the ground or on fallen logs, and exceptionally will even forage on walls; occasionally flycatches. May join mixed-species foraging flocks.

Breeding. Season in most of range May–Jul, although may begin in Apr, especially in S & W USA; from Mar in S Mexico; single-brooded. Nest built by female, male may bring materials, construction work taking 6–30 days, foundation of twigs and wood and bark chips, sometimes bound with spider webs and egg cases, supporting cup of finer bark shreds, wood fibres, moss, plant down and sometimes hair or feathers (base often crescent-shaped, with ends higher than cup), 0.6–22.5 m above ground and usually well concealed between trunk and a loose flap of bark on large tree or stump, usually dead or dying (both deciduous and coniferous trees utilized); rarely, placed in natural cavity such as knothole or abandoned woodpecker (Picidae) excavation, even in fence post, and exceptionally behind loose shingles on building, or under piece of tin on outhouse roof; specially designed artificial nest-sites also accepted. Clutch 1–9 eggs, usually 5–6, white, variably but usually sparsely spotted reddish-brown, larger markings sometimes concen-

trated at larger end, average size 15.4 × 11.7 mm (nominate race), replacement laid if first clutch lost; incubation by female, fed at nest by male, period 13–17 days; female also broods chicks, which are fed by both parents, nestling period 13–20 days; fledglings remain with, and dependent on, adults for up to at least 17 days.

Movement. Resident and migratory. Present all year as far N as coast of S Alaska, S Canada (regular E British Columbia, C Alberta, SC Saskatchewan and Manitoba) and coasts of Maritime Provinces, but partial post-breeding withdrawal from N of range, and most E & N populations appear to be strongly migratory. Centre of gravity of population shifts S in winter, thus uncommon in winter in SE Canada (Ontario, Quebec) and NE USA (the Dakotas E to Maine, New Hampshire and Rhode Island), and rare in winter in Saskatchewan, Manitoba and Newfoundland. Common on passage in Ontario, Minnesota, Iowa, Missouri, Wisconsin, Michigan, Illinois, Indiana and E to Massachusetts and New Jersey, and fairly common Rhode Island. Immature ringed in Port Huron (Michigan) on 4th Oct recaptured 10 days later 442 km to W in Wisconsin; other long-distance movements include Ontario to North Carolina (877 km), Quebec to New Jersey (695 km), Massachusetts to New Jersey (423 km), Wisconsin to Arkansas (1262 km), Ohio to Virginia (522 km). Some N birds winter irregularly S throughout E USA to C Florida (and rarely to S Florida), Gulf Coast, Texas, and NE Mexico (Coahuila and C Nuevo Leon, casually to C Tamaulipas). Farther S, some populations migrate latitudinally or altitudinally, and S races appear to be sedentary or local migrants. In W, uncommon winter visitor to riverine woodland in S Arizona (especially around Camp Verde and Tucson, rarely W to lower R Colorado); also occasional records from NW Sonora and casually to C Sonora. In S California a rare autumn and winter visitor to coastal lowlands and Channel Is, also rare in desert (primarily in autumn). Migrants penetrate S of breeding range from late Aug onwards, main passage period Sept to mid-Nov; does not usually occur in moderate numbers until mid-Sept in NE and Oct–Nov in Florida, Gulf States, Texas and Arizona. Return passage N Mar to mid-May, most birds having left S areas by mid-Apr and NE by May. In Mexico extreme dates for N migrants are 9th Nov and 18th Apr. Vagrants recorded N to S Yukon (summer records at L Dezadeash and L Tagish), and in W Atlantic on Bermuda (3–4 in Nov 1870, at least 7 in Oct 1970, 1 in Nov 1987).

Status and Conservation. Not globally threatened. Fairly common in summer in most of breeding range; uncommon in Alaska, Alberta, Saskatchewan, Newfoundland, New Brunswick, Prince Edward I, Montana, South Dakota, Wisconsin, Michigan, E USA seaboard from Massachusetts S to Maryland, also S Appalachians and Texas. In NE parts of US range breeding sporadic or very local, thus rare in summer in North Dakota, Nebraska, Iowa, Missouri, Illinois, Indiana and Ohio. Generally fairly common to common in Mexico, although uncommon in Oaxaca; common in Guatemala. Current data on population trends indicate that the species is stable in most areas in North America. Some recent expansion in NE USA, spreading into SW & SE Pennsylvania, with extension S down E coast since 1960s; also, increase in New England, probably owing to regrowth of forests, and widespread mortality of elms (*Ulmus*) due to Dutch elm disease may have temporarily helped the species; in addition, S of main range breeding has apparently become more regular in Mississippi Basin, this perhaps due to maturation of relict swamp-forests (or better observer coverage), and breeding range has evidently expanded in mid-Atlantic states and California. On other hand, local extinctions caused by habitat loss in New York, Michigan and lower Colorado Valley, and numbers have declined since pre-settlement times in W North America as a result of loss of mature and old-growth trees; highly likely that numbers have continued to decline owing to logging and other forestry practices.

Bibliography. Anon. (1998b), Baptista & Johnson (1982), Baptista & Krebs (2000), Bent (1948), Campbell *et al.* (1997), Davis (1979), DeSante & Pyle (1986), Franzreb (1985), Gorney (2000), Harrap & Quinn (1996), Hejl *et al.* (2002), Hellmayr (1934), Macoun & Macoun (1909), Shaffer & Alvo (1996), Thielcke (1962), Tietze (2007), Tietze *et al.* (2006), Webster (1986a, 1986b).

4. Short-toed Treecreeper

Certhia brachydactyla

French: Grimpereau des jardins **German:** Gartenbaumläufer **Spanish:** Agateador Europeo

Taxonomy. *Certhia brachydactyla* C. L. Brehm, 1820, Roda Valley, Thuringia, Germany.

Recent genetic evidence (cytochrome *b*) indicates that this species is closest to *C. americana*. Geographical variation slight and largely clinal, but N African race *mauritanica* exhibits moderately well-marked genetic and also vocal differences from European races and may merit separate species status; further study required. Nominative race and *megarhynchos* intergrade in C Pyrenees, W & S Spain and S Portugal. Racial affiliation of birds in Caucasus uncertain, currently included in *stresmanni*; similarly, those on larger Ionian Is (Greece) placed with *dorotheae*, but further study needed. Proposed race *rossocaucasica* (described from Sochi-Khosta region of NW Caucasus) possibly worthy of recognition; *harterti* (described from NW Turkey) is considered a synonym of nominate. Five subspecies currently recognized.

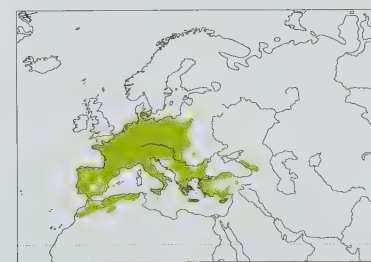

Subspecies and Distribution.

C. b. megarhynchos C. L. Brehm, 1831 – Channel Is, W & N France, Belgium, Netherlands and W Germany S to NW Spain and Portugal.

C. b. brachydactyla C. L. Brehm, 1820 – S Denmark, Poland and extreme S Lithuania S to E & SE France, Spain (except NW), C Germany, Italy, Sicily, Greece (except S), Hungary, W Ukraine, very locally Romania, and W Turkey.

C. b. mauritanica Witherby, 1905 – Morocco (S to Moyen and Haut Atlas), Algeria (S to Atlas Saharien and Aurès range) and NW Tunisia.

C. b. dorotheae E. J. O. Hartert, 1904 – S Greece (and most of larger Ionian Is), Crete and Cyprus. *C. b. stresmanni* Kummerlöwe & Niethammer, 1934 – C Turkey; also foot of W Caucasus on Black Sea coast (E at least to NC Georgia).

Descriptive notes. 12.5 cm; 7.5–11 g. Nominative race in fresh plumage (autumn and winter) has feathers of crown and nape rather dark brown, fringed blackish, with narrow off-white shaft streaks, lores blackish, supercilium greyish-white to brownish-white (usually indistinct or absent in front of eye), ear-coverts mottled white, black and brown; mantle and scapulars as crown but only tips of feathers blackish, and off-white centres broader (streaking well defined); rump and upperpart-coverts cinnamon-rufous, feather centres whitish (may reach tip of shaft), concealed base blackish; lesser upperwing-coverts brown, tipped orange-buff, median and greater coverts black-brown, medians tipped orange-buff and centred whitish, greater fringed and broadly tipped pale buff to rufous-brown (sometimes with pale shaft streak); alula and

primary coverts black-brown, tipped pale buff. largest feather of alula often with complete pale fringe on outer web; inner webs of tertials medium brown to light brown, outer webs dark brown, black from centre towards tip, with narrow buff-white fringe and broad white tip; primaries and secondaries medium brown, all of these except outer three or four primaries having pale buff band across feather (restricted to outer web on P4/P5, primaries numbered ascendingly), bordered on each side by blackish-brown band, feathers fringed orange-buff distally of bands (especially on secondaries) and tipped off-white; tail feathers pale brown, slightly darker around shaft, which is pale rufous-brown; throat and underparts greyish-white to pale grey, breast and belly usually variably washed rufous-brown or brown, flanks washed rufous-brown, undertail-coverts pale rufous-brown with whitish tips, thighs pale grey; iris brown; upper mandible dark brown, cutting edges paler, lower mandible pale brown with dark brown tip; legs pale brown. Distinguished from extremely similar *C. familiaris*, often with great difficulty (separation of the two sometimes impossible), by duller supercilium which is also shorter, narrower and less prominent (often inconspicuous in front of eye, and supercilia never meet above bill base), duller underparts more often sullied dirty buff on breast and flanks (some have only throat pure white), but mainly by voice; separation very difficult also in the hand, requiring detailed biometrics and careful examination of exact pattern of wing feathers. Sexes similar. Juvenile is as adult but upperparts more spotted (less streaked), and has some small brownish or grey spots on underparts. Races vary minimally, mainly in size and coloration: *megarhynchos* is on average slightly paler and warmer brown than nominate and with whitish streaking on upperparts somewhat less well defined; *mauritanica* is poorly differentiated, resembles nominate but with slightly darker and colder upperparts, pale streaks on crown generally narrower and less conspicuous, underparts less whitish, with breast and flanks more extensively washed dull buff; *dorotheae* is also poorly marked, as nominate but slightly duller greyish earth-brown above, bill longer; *stresemanni* is like last, but bill not so long. Voice. Calls similar to those of *C. familiaris* but louder, more emphatic and more varied, include diagnostic, clear, explosive "tyt" or "tut", likened in quality to call of Dunnock (*Prunella modularis*) or Coal Tit (*Periparus ater*), given singly, in slow series at well-spaced intervals, in fast series (almost trills), or in characteristic short phrase with "dripping" rhythm which accelerates and falls slightly in pitch ("tyt...tyt, tyt tyt-tyt"); occasionally a loud, penetrating "tsree" (similar to that of *C. familiaris*, although fractionally lower-pitched), both singly and in series at varying speeds, as a contact call and in intraspecific disputes, this sometimes combined with "tyt" call (helpful for identification purposes); high calls include quiet, thin, high "si", "sit" or "isup" (only subtly different from analogous calls of *C. familiaris*). Full song, by male, throughout year (especially Mar–Jul), a stereotyped phrase rising in pitch towards end, comprising 6 (4–9) loud, clear, sweet whistled notes, evenly spaced but with slightly "jolting" rhythm, rapidly and energetically delivered, begins with "tyt" calls and terminates with "tsree" notes, "tyt, tyt, siri-toi-see", c. 1.1–1.5 seconds in duration (shorter, lower-pitched, louder and more emphatic than song of *C. familiaris*); some songs abbreviated to 3–4 notes (notably in Denmark); each male has 1–3 song types, and there are also regional dialects within Europe, but these variations generally distinguishable only in sonagrams. N African race (*mauritanica*) has different, lower-pitched song, often starting with "tyt" note but then longer and more jumbled (and elicits no response from European races), and song on Cyprus (*dorotheae*) is very short and simple, of 3–6 units (again, producing little response from European races). This species sometimes imitates song of *C. familiaris*, but latter is the more frequent mimic.

Habitat. Mixed and broadleaf deciduous woodland, particularly oak (*Quercus*), favouring edge habitats, as well as pine (*Pinus*) forest (especially in S), riverine willows (*Salix*) and poplars (*Populus*), copses, orchards and parks, usually with dense understorey, well-wooded farmland and suburban areas, and sometimes plantations of rough-barked exotic conifers; generally avoids pure stands of fir (*Abies*), spruce (*Picea*) and beech (*Fagus sylvatica*). In S Spain, prefers open forest of cork oak (*Quercus suber*) or stone pine (*Pinus pinea*) with some shrubby undergrowth, and groves of olives (*Olea*), and in N Africa found in pine, cedar (*Cedrus*) and oak woodland. Overall, essential requirement is for stands of mature rough-barked trees. In N portion of range usually found below 1000 m, but in S occurs at higher altitudes, e.g. in SE France to 1800 m, in S Switzerland to c. 1400 m, in Greece to tree-line at c. 1800 m, and to 2000 m in Algeria and Turkey; in Morocco occurs locally near sea-level but otherwise montane, at 800–2200 m, occasionally to 2500 m in juniper (*Juniperus*) woodland.

Food and Feeding. Food mainly insect larvae and pupae, and spiders (Araneae), also some seeds. Forages on trunks and larger boughs of trees, sometimes among outer foliage, using fine bill to extract prey from cracks and crevices. Works upwards in jerky hops, spiralling around trunk, and then flies to bottom of another tree and repeats process. Foraging behaviour very much like that of *C. familiaris* but a little slower and less agile, making more spirals and hops and moving more quickly onto side branches. Occasionally forages on walls and buildings, fences and the like. Often joins mixed-species foraging flocks, sometimes with *C. familiaris*.

Breeding. Season Apr to mid-Jun, occasionally from late Mar; usually double-brooded. Apparently occasionally polygynous, also simultaneous bigamy (two females incubating eggs and feeding young at same time in same nestbox) recorded. Usually male builds two or three nest foundations and female selects one for completion, the process taking up to 32 days; foundation made from twigs, conifer needles, grass, bark, plant fibres, cloth, paper etc. (often large and untidy, filling nesting cavity), lined with feathers, hair, down, rootlets, moss and lichen, most nests sited 0.5–4 m above ground, only a few above 10 m, placed behind bark flap or in crack or crevice in tree trunk, including abandoned woodpecker (Picidae) hole, or in cavity in building (wooden or stone) or woodpile, sometimes behind ivy (*Hedera*), in base of raptor nest or squirrel (Sciuridae) drey, exceptionally in tangle of twigs close to tree trunk; will use specially designed nestboxes; in Morocco in hole or narrow crack or fork of trunk, rarely behind bark flap. Clutch 4–9 eggs, usually 5–7, white, with reddish-purple and reddish-brown (sometimes very faint) spots and blotches concentrated at broader end, average size 15.6 × 12.2 mm (race *megarhynchos*); incubation by female, period 13–15 days; chicks brooded by female, fed by both sexes, nestling period 15–18 days; young probably disperse quickly; male may start new nest while female still feeding first brood, and when chicks 10–12 days old male takes over the feeding of them while female completes second nest, sometimes laying second clutch before first-brood young have fledged.

Movements. Resident, with some altitudinal movement; otherwise rather strictly sedentary, with very limited post-breeding dispersal and few ringing recoveries at distances of more than 10 km, but few may move slightly longer distances Sept–Oct and Mar–Jun. Vagrant NW Belarus, NW Russia, Sweden and England; rare straggler in Ukraine.

Status and Conservation. Not globally threatened. Generally fairly common, but scarcer towards N & E of range; rare in Caucasus. Breeding densities ranging from 0.5 pairs/10 ha to 5–6 pairs/10 ha. European populations probably stable, although loss of prime habitat has almost certainly led to reduction in numbers in many areas. Expanded into E Poland in 20th century and has similarly colonized Denmark, where first bred in 1946 and c. 300 pairs by 1980s. Status in Corsica uncertain; recorded Jan 1908, and tape recordings of three singing individuals made in Apr 1969 were identified as being of this species (song of N African race *mauritanica*); there have been no subsequent records.

5. Bar-tailed Treecreeper

Certhia himalayana

French: Grimpereau de l'Himalaya

Spanish: Agateador del Himalaya

German: Himalajabaumläufer

Other common names: Himalayan Treecreeper

Taxonomy. *Certhia himalayana* Vigors, 1832, Himalayas (Garhwal and Kumaon).

Closest relatives uncertain, although song rather similar to those of *C. discolor* and *C. manipurensis*. Despite this species' occurrence in two disjunct populations, geographical variation is clinal across whole range, W birds being palest with longer bill and E birds darker and shorter-billed (cline is apparently reversed at extreme E parts of range). Pronounced local individual variation tends to mask geographical variation. Four subspecies recognized.

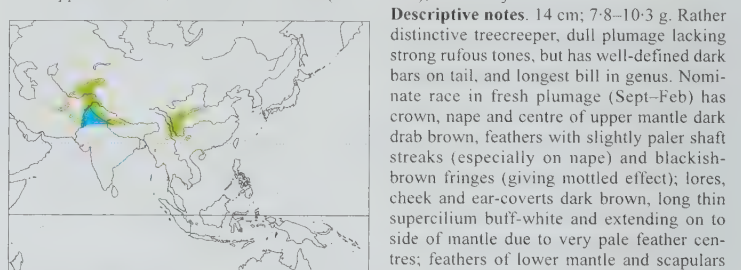

Subspecies and Distribution.

C. h. taeniura Severtsov, 1873 – mountains of C Asia in E Uzbekistan, W Kyrgyzstan, extreme SE Turkmenistan, W Tajikistan and N Afghanistan.

C. h. himalayana Vigors, 1832 – breeds E Afghanistan (S of Hindu Kush, from Nuristan S to Kandahar), N Pakistan (S at least to C Baluchistan, also in Murree Hills) and E in Himalayas (also N of main range, in upper Indus and associated valleys) to W Nepal.

C. h. yunnanensis Sharpe, 1902 – S China (from SW Gansu and S Shaanxi S to SE Xizang, NW & W Yunnan and W Sichuan, also SW Guizhou) and N Myanmar.

C. h. ripponi Kinnear, 1929 – S Chin Hills (Mt Victoria), in SW Myanmar.

Descriptive notes. 14 cm; 7.8–10.3 g. Rather distinctive treecreeper, dull plumage lacking strong rufous tones, but has well-defined dark bars on tail, and longest bill in genus. Nominative race in fresh plumage (Sept–Feb) has crown, nape and centre of upper mantle dark drab brown, feathers with slightly paler shaft streaks (especially on nape) and blackish-brown fringes (giving mottled effect); lores, cheek and ear-coverts dark brown, long thin supercilium buff-white and extending on to side of mantle due to very pale feather centres; feathers of lower mantle and scapulars with whitish centres, fine warm brown sub-terminal markings and fine blackish-brown fringes (giving mealy, dark-scalloped appearance on paler ground), feathers of back and rump dull cinnamon-orange subterminally with light olive-brown tips, uppertail-coverts light olive-brown, faintly barred darker; upperwing-coverts dark brown, lessers and medians tipped buff-white, inner greater with pale buff shafts and dull buff-white tips; alula and primary coverts dark brown, feathers of alula tipped dirty white on outer web; tertials medium-brown, barred dark brown, outer webs with subterminal dark brown spot and whitish tip, secondaries drab brown, slightly warmer on outer feathers, with dark subterminal band and off-white tip, dark brown central portion and base separated by pale orange-buff band; primaries medium brown, drab brown on distal part of outer webs, P3–P4 (primaries numbered ascendingly) barred dark brown inwards of emarginations, P5–P10 dark brown at base and in centre with intervening pale orange-buff band (as on secondaries); tail medium drab brown with narrow dark brown bars, pale rufous-brown shafts; chin, throat and centre of upper breast creamy white, sides of neck and breast washed pale buff, lower breast, upper flanks and belly very pale drab-buff, rear flanks and thighs to undertail-coverts pale drab brown (when plumage very fresh may show fine dark fringes on breast and belly, giving faint scalloped effect); in worn plumage (Mar–Aug) crown and nape look more distinctly streaked and warm tones on mantle and scapulars lost, underparts paler and whiter (dingy pale grey when heavily worn); iris dark brown; upper mandible dark horn-brown to blackish, lower mandible pale fleshy with brown tip; legs brown to fleshy-coloured. Distinguished from all congeners by thin blackish bars on tail. Sexes similar, male on average slightly longer-billed than female. Juvenile is as adult but feather centres of forehead to nape larger, browner and less distinct, giving more mottled appearance, upperparts slightly warmer and browner, more blotched (less scalloped), throat and breast whiter (but blotchy, grey feather bases showing), contrasting more sharply with drab-buff lower underparts, with fine dark feather fringes forming scattered faint dark spots or scallops. Race *taeniura* is paler and greyer than nominate, with pale feather centres of upperparts greyer and darker fringes narrower and pale brown (rather than black-brown), rump and tail paler grey (rump with reduced warmth but same relative contrast with upperparts), paler and greyer below with little or no buff wash, even when fresh (except on lower belly and vent), and less contrast between throat and breast, bill longer; *yunnanensis* is darker than nominate, upperparts blackish-brown and breast and belly darker, more smoky buff (but slightly paler in NE Sichuan); *riponi* resembles last, but upperparts slightly warmer and paler brown (still darker than nominate), with more obvious rufous tinge on lower back and rump. Voice. Song of usually 7–12 (extremes 3–13) full, slightly disyllabic, whistled notes given in slow, deliberate rattle, c. 6 notes per second (up to 12 in fastest songs), often slightly decelerating, and introduced by higher, sweeter note, each song typically c. 2 seconds in duration, e.g. "tswee-chi-chi-chi-chi-chi-chi", similar to that of *C. discolor* but tends to be slower and more halting. Also a more conversational, tinkling, descending (almost laughing) "ti, ti-tu-du-du-du". Call a short, thin, high-pitched, piercing "tsee", singly or in slow series, "tsui, tsui, tsui...", also much thinner and higher "see" and "psit" notes.

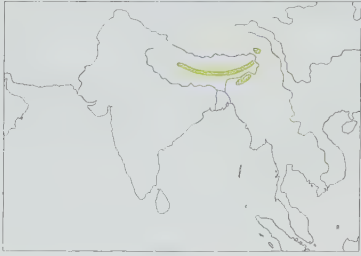

Habitat. Breeds in open coniferous forest and forest edge. In C Asia, N Afghanistan and W Pakistan (Baluchistan) favours mature juniper (*Juniperus*) forest; in E Afghanistan, N Pakistan, W Himalayas and S China occurs in forests of pine (*Pinus*), spruce (*Picea*), cedar (*Cedrus*) and fir (*Abies*), as well as peach (*Prunus persica*) and apricot (*Prunus armeniaca*) orchards, and rhododendron (*Rhododendron*), juniper and birch (*Betula*) at high altitudes, also in more arid treeless regions of trans-Himalaya; on Mt Victoria (SW Myanmar) exclusively in mature pine forest. In winter on plains of Pakistan and NW India, may be found in acacia (*Acacia*) groves, riverine woodland, orchards, village trees, gardens and roadside avenues, even when these isolated in otherwise treeless semi-desert. W populations breed at 1800–3660 m (towards lower end of range in W, at higher end in Nepal), and in winter from 2100 m down to plains level although some remain as high as 2400 m; E populations occur to 4000 m in summer and down to 650 m in winter, but limits of breeding distribution unclear.

French: Grimpereau discolore **German:** Sikkimbaumläufer **Spanish:** Agateador Gorjipardo
Other common names: Brown-throated Treecreeper (when treated as conspecific with *C. manipurensis*)

Taxonomy. *C[erthia] discolor* Blyth, 1845, Darjeeling, India.

Formerly treated as conspecific with *C. manipurensis*, but now separated on basis of vocal and genetic evidence. Birds from NE India (Nagaland, W Manipur) sometimes placed with *C. manipurensis*, but plumage details indicate clear affiliation with present species. Monotypic.

Distribution. E Himalayas in C & E Nepal (E from Dhaulagiri massif) E to NE India (E to E Arunachal Pradesh, also S of R Brahmaputra in Nagaland and W Manipur); also S Xizang (Chumbi and Tsangpo valleys), in SW China.

Descriptive notes. 14 cm; 8–12.5 g. In fresh plumage (from Sept onwards), feathers from forehead to mantle are cinnamon-brown with paler buff shafts and dark brown fringes (neat pattern of pale buff spots on crown and upper mantle, more scaled appearance on lower mantle and scapulars); lores dark brown, supercilium flecked pale buff with odd whitish feathers, not well demarcated from crown, although broader and whiter behind eye; cheek and ear-coverts dark brown, ear-coverts tipped buff; lower back, rump and uppertail-coverts orange-rufous; lesser upperwing-coverts as mantle, median coverts blackish-brown, tipped cinnamon-buff, greater coverts dark brown, inners with buff tip, shaft streak and fringe on outer web, outers tipped buff; alula and primary coverts dark brown, alula tipped pale buff, largest feather also fringed pale buff; tertials dull buff, inner webs washed brown, outer webs with dark brown subterminal band adjacent to shaft on distal half, separated from dark brown basal half by buff band; secondaries dark brown, tipped pale buff, with pale band across base buffy white on outer web (buff notch on distal quarter); pale brown on outer webs, P5–P10 with pale notch on distal quarter of outer web and crossed by pale band at base (continuous with band on secondaries), also P6–P10 tipped pale grey; tail dull cinnamon, shafts pale rufous; throat and breast light drab-buff, becoming paler on rear flanks, belly and vent (when plumage very fresh, faint darker tips sometimes visible on chin, throat and side of neck), undertail-coverts warm buff, axillaries and underwing-coverts white; in worn plumage (spring–summer) underparts on average slightly duller, dingier and less buffy, belly slightly darker and duller, sometimes (when very worn) pale streaks on crown and nape narrower and better defined; iris reddish-brown to dark brown, almost black on culmen, lower mandible pale horn to whitish with darker tip; legs pale flesh-brown to dark brown. Distinguished from *C. himalayana* by plain unbarred tail, and from *C. hodgsoni* and *C. nipalensis* also by dull underparts with pale brown wash on throat and breast, and lack of contrastingly cinnamon flanks. Sexes similar. Juvenile is as adult but shorter-billed, with fine dark scallops on throat and breast, which are tinged cinnamon-buff. Voice. Song a monotonous, fast rattle lasting 1–2 seconds, of simple, full “chi” notes at c. 12 per second, slightly accelerating and, more obviously, gaining in power and volume towards end, “chi’chi’chi’chi...”. Call an explosive, deliberate, disyllabic “chi-tip”.

Habitat. Mature broadleaf forest, both deciduous and evergreen, especially mossy oak (*Quercus*) forest, less frequently rhododendrons (*Rhododendron*). In Himalayas summers at 1600–2750 m, with most records above 2000 m, exceptionally as high as 3300 m, and in winter regularly down to 1000 m, exceptionally to 300 m, but also as high as 3050 m; in Nagaland and Manipur (NE India) found at c. 800–2300 m. Occupies lowest altitudinal belt of the four species of treecreeper found in Himalayas and associated ranges, normally overlapping in breeding season only with *C. nipalensis*; in non-breeding season, however, this separation obscured by altitudinal movements.

Food and Feeding. Food insects and spiders (Araneae). Foraging behaviour typical of the genus, creeping jerkily on moss-laden and lichen-covered trunks and boughs of trees and picking prey items from crevices and cracks. Found singly and in pairs; in non-breeding season also in groups of up to five individuals in mixed-species foraging flocks.

Breeding. Season probably Mar–May in Himalayas. No other information.

Movements. Resident, but some altitudinal movements and perhaps also some dispersal in winter. Records from N India (E Uttaranchal) in Jun and extreme W Nepal (near Dhangarhi) in Mar presumably involve stragglers.

Status and Conservation. Not globally threatened. Fairly common in Himalayas, becoming more abundant in E. In NE India, old unconfirmed records from Meghalaya (Khasi Hills) and S Assam (Cachar Hills). Poorly known species, e.g. no documented breeding records from Nepal or Bhutan.

Bibliography. Ali & Ripley (1983), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1983), Harrap & Quinn (1996), Inskipp & Inskipp (1991), Li Dehao & Wang Zuxiang (1979), Martens (1981), Martens & Eck (1995), Martens & Tietze (2006), Rasmussen & Anderton (2005b), Spierenburg (2005), Stuart Baker (1922), Thet Zaw Naing (2003), Tietze (2007), Tietze *et al.* (2006), Vaurie (1950b).

9. Manipur Treecreeper

Certhia manipurensis

French: Grimpereau du Manipur **German:** Manipurbaumläufer **Spanish:** Agateador de Manipur
Other common names: Brown-throated Treecreeper (when treated as conspecific with *C. discolor*)

Taxonomy. *Certhia manipurensis* Hume, 1881, Manipur, India.

Formerly treated as conspecific with *C. discolor*, but now separated on basis of vocal and genetic evidence. Birds from NE India (Nagaland, W Manipur) sometimes placed with present species, but plumage details indicate clear affiliation with *C. discolor*. Birds from SW Myanmar (Arakan Yomas) tentatively included in nominate race, but racial identity requires examination. Four subspecies recognized.

Subspecies and Distribution.

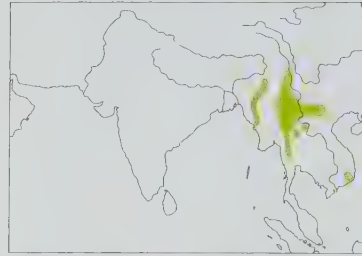

C. m. manipurensis Hume, 1881 – NE India (S Manipur, E Mizoram) and W Myanmar (Chin Hills, Arakan Yomas).

C. m. shanensis Stuart Baker, 1930 – NE & E Myanmar (S to the Karenni), S China (Yunnan from Gaoligong Shan S to Tengchong), NW Thailand and NW Vietnam (Fansipan massif, in W Tonkin).

C. m. laotiana Delacour, 1951 – Tranninh Plateau (around Xieng Khouang), in NC Laos.

C. m. meridionalis Robinson & Kloss, 1919 – Da Lat Plateau, in S Vietnam.

Descriptive notes. 14 cm; 9–11 g. Nominative race in fresh plumage has feathers of forehead to mantle orange-buff with paler buff shafts and dark brown fringes (forming spots on crown and upper mantle, scaled pattern on lower mantle and scapulars); lores dark brown, supercilium flecked pale buff with odd whitish feathers, not well demarcated from crown, although broader behind eye; cheek and ear-coverts dark brown, ear-coverts tipped buff; lower back, rump and uppertail-coverts orange-rufous; lesser upperwing-coverts as mantle, median coverts blackish-brown, tipped cinnamon-buff, greater coverts dark brown, inners with buff tip, shaft streak and fringe on outer webs, outers tipped buff; alula and primary coverts dark brown, alula tipped pale buff, largest feather also

breast rich cinnamon or cinnamon-orange, belly and vent duller and paler (pale drab-cinnamon or drab-buff), undertail-coverts rich cinnamon, thighs light drab-buff; in worn plumage underparts slightly duller; iris reddish-brown to dark brown; upper mandible horn-brown to dark brown, almost black on culmen, lower mandible pale horn to whitish with darker tip; legs pale flesh-brown to dark brown. Differs from *C. discolor* in rather warmer and more richly coloured general appearance, with rich cinnamon underside. Sexes alike. Juvenile is as adult, but with fine dark scales on throat and breast. Races differ only moderately: *shanensis* has colder and greyer feathers centres above (especially on crown and nape) than nominate, below rather darker, dingier and less buff, throat and breast drab-grey, belly dull grey, undertail-coverts buff or cinnamon-buff; *meridionalis* resembles previous, but crown and nape slightly paler and buffier, upperparts much warmer, feathers rufous with finer dark fringes (especially on mantle, back and scapulars) and only slightly paler shaft streaks, back and rump slightly richer and more rufous, underparts perhaps darker and purer grey on average; *laotiana* is as last, but upperparts less rufous and much more strongly marked black and bright tawny, undertail-coverts slightly brighter rufous. Voice. Song a monotonous rattling repetition of paired notes, 5–7 pairs per second, e.g. “tchi-chi, tchi-chi, tchi-chi...” or “chid-de chid-de-chid-de...”; speed of rattle approaches that of *C. discolor* song, but disyllabic units impart halting or “trotting” rhythm. Calls include high, soft, thin “tsit”, rather lower-pitched, explosive, deliberate, disyllabic “chid-ip” (very like that of *C. discolor*), full explosive “tchiu!” and hard “chip”; calls sometimes extended into short, rattling “chi’r’r’r’it”.

Habitat. Moist hill evergreen forest; locally also pine (*Pinus*) forest, especially when in association with stands of broadleaf trees. In India (Manipur) found at c. 800–2300 m (but records not distinguished from those of *C. discolor*); in Myanmar, breeding proven at 1830 m in N Chin Hills and recorded at 1400–3000 m farther S (on Mt Victoria), and noted at 2135–2195 m in NE and 1465–2285 m in SE; in S China (Yunnan) recorded at 2000–3050 m, in Thailand from 1370 m to at least 2440 m, and in Vietnam above 2000 m in NW and 1000–2500 m in S.

Food and Feeding. Food and behaviour typical of the genus, but no specific information.

Breeding. Poorly known. Season Apr–May in India (Manipur) and W Myanmar (N Chin Hills), and fledged young seen end Mar in SW Myanmar (Mt Victoria); pair at nest in early Feb and juvenile recorded in early May in NW Thailand; season about Jan–Jul in S Vietnam. Nest a pad of fibre, moss and a few roots, lined with few feathers, placed 2.4–3.7 m above ground in shallow hole in small tree. Clutch 3–4 eggs, white, densely blotched and freckled with pale reddish or reddish-brown, marks sometimes concentrated towards broader end, average size c. 15.9 × 12.3 mm (nominate race). No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Not uncommon in Myanmar, and common there in SE; uncommon in Thailand, and very rare in NW Vietnam. Now absent or, at best, very rare at Doi Suthep-Pui National Park (Thailand), where it was formerly not uncommon.

Bibliography. Ali & Ripley (1983), Harrap & Quinn (1996), Hopwood & Mackenzie (1917), Martens & Tietze (2006), Rasmussen & Anderton (2005b), Robson (2000b, 2002c), Smythies (1986), Stresemann & Heinrich (1940), Stuart Baker (1922, 1932), Tietze (2007), Tietze *et al.* (2006).

Subfamily SALPORNITHINAE

Genus *SALPORNIS* G. R. Gray, 1847

10. Spotted Creeper

Salpornis spilonotus

French: Grimpereau tacheté **German:** Stammsteiger **Spanish:** Agateador Moteado
Other common names: Spotted Treecreeper, Spotted Grey Creeper

Taxonomy. *Certhia spilonota* Franklin, 1831, between Calcutta and Benares, India.

Has been placed in Sittidae or treated as a monospecific family, Salpornithidae, mainly due to lack of stiffened tail feathers. Data derived from DNA–DNA hybridization indicate present genus is closest relative of *Certhia*. Recent research using biometrics, song structure and cytochrome *b* sequences supports treatment as a separate family with closest but still loose relationship to Tichodromidae; also calls for specific separation of African birds as *S. salvadori*. In contrast, other studies suggest distinct vocal differences exist between, on the one hand, Indian and W African birds and, on the other, S African populations, and these two groups might represent two separate species; further study required, e.g. of Ethiopian birds. Six subspecies currently recognized.

Subspecies and Distribution.

S. s. emini Hartlaub, 1884 – Gambia S to W Guinea, NW Sierra Leone and N Ivory Coast E discontinuously to N Ghana, Burkina Faso, Nigeria, N Cameroon, S Chad (S from Azoum/Chari confluence) and N Central African Republic; also S Sudan, adjacent NE DR Congo (NE Uele) and extreme NW Uganda.

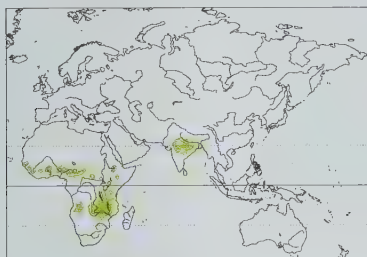

S. s. erlangeri Neumann, 1907 – W & SE Ethiopian Highlands.

S. s. salvadori (Bocage, 1878) – extreme E Uganda and adjacent highlands of W Kenya; also C Angola, S & SE DR Congo, most of Zambia, NE, W & S Tanzania (S from near SE of L Victoria in W and from Songea and Liwale in SE), Malawi and N Mozambique (S to R Zambezi).

S. s. xylodromus Clancey, 1975 – N & C Zimbabwe (Zambezi Escarpment and Mashonaland Plateau) and adjacent Mozambique (Manica platform S to R Save).

S. s. rajputanae R. Meinertzhagen, 1926 – C & SE Rajasthan (E from Sambhar, Ajmer, Aravalli Hills and Mt Abu), in WC India.

S. s. spilonotus (Franklin, 1831) – C India from E Gujarat (E from Rajpipla and Disa) and S Haryana (Gurgaon) E to N Uttar Pradesh (Gonda, near Nepalese border) and N Bihar, S to E Maharashtra, N Andhra Pradesh and SE Madhya Pradesh (Bastar District).

Descriptive notes. 15 cm; 14 g, 13.5–16 g (Africa). Very distinctive if seen well, with spotted and barred plumage, long, slender, decurved bill and bark-gleaning habits; tail slightly rounded and, unlike *Certhia*, not used for support while climbing; flight undulating. Nominate race in fresh plumage (from about Oct onwards) has forehead drab brown, crown and nape very dark brown with buff-white shaft streaks, long, broad off-white supercilium, dark brown lores and upper ear-coverts, off-white cheek and side of neck, some dark brown fringes on side of neck; upperparts very dark brown, feathers tipped white, extreme tips narrowly margined brown (white bases fully concealed); lesser upperwing-coverts pale drab-grey with dark brown subterminal bar, median and greater coverts dark brown with white spots at tip and at base of shaft; alula drab brown, slightly paler at tip, primary coverts drab brown with off-white fringes at tip and a white notch centrally on outer web; flight-feathers dark brown, tertials with off-white notches along fringe of outer web and white tips, secondaries and primaries (except outer two) similar but white tips much reduced on primaries and P3–P5 (primaries numbered ascendingly) unmarked distally of emarginations (flight-feathers with concealed white bars on inner webs); tail dark brown, boldly barred white, central pair of rectrices with extensive pale drab-grey areas along shaft and at tip; chin and throat white, poorly demarcated from underparts, feathers of which white with bold brown bars and narrow cinnamon-brown margins (appearing variably spotted and barred brown and white), variable cinnamon fringes may produce cinnamon wash over entire underparts; in worn plumage (from about May onwards) white spotting on upperparts and wings reduced; iris dark brown; bill blackish-horn or brownish-horn, lower mandible and cutting edge of upper mandible flesh-coloured or pale horn; legs greyish or purplish-grey to blue-black. Sexes similar. Juvenile is as adult, but notches and spots on wings tinged buff, primaries and secondaries broadly fringed off-white at tip, throat and upper breast finely scaled or streaked darker (appearing mottled or scaled more than spotted). Races vary relatively little, mainly in colour and intensity of markings above and below: *rajputanae* has ground colour above slightly paler and browner than nominate, with white spotting slightly less profuse, scapulars slightly plainer and greyer, and underparts (not throat) washed cinnamon and dark markings reduced to narrow black bars; *emini* resembles nominate but slightly paler and browner above, pale spots on average larger and not so pure white, underparts slightly whiter with reduced cinnamon wash (adult has pale fringes at tips of flight-feathers and dark fringes on throat, i.e. as juvenile of nominate); *erlangeri* resembles previous, but spots above variably washed rufous-buff, especially on crown, mantle and back (and ground colour darker), underparts washed cinnamon-rufous and with bolder and blacker bars and more white spotting, bill shorter; *salvadori* has underparts as previous but ground colour paler, more buffy white, feathers with rather narrower dark bars and tips, a reduced cinnamon-buff wash and more extensive white areas, upperparts as *emini* but white spots generally larger and a variable slight buff wash, primaries more boldly fringed white at tips, bill shorter; *xylodromus* is as last but starkly black and white, with upperparts sooty black (not dark brown), pale subterminal barring whiter (buff wash reduced), terminal spots purer white, tail more sharply black and white, throat whiter, underparts paler buff. **VOICE.** Calls in India include a series of full, strident, rising notes, “tui-tui-tui”, while in W Africa recorded as giving single, high-pitched “tsee”; in S Africa calls include high-pitched, very thin “tse-cet” and 5–6 high, even croaking notes, “kek-kek-kek-kek”, said to be reminiscent of a coot (*Fulica*). Song in India and W Africa a short, simple series of clear, slightly plaintive whistled notes, e.g. “tsit-tsee tuu tuui-tuwec” with slight variations (when excited, e.g. after playback, gives longer and faster but more rambling song); E & S African birds have much higher-pitched, almost lisping phrase, “tsit’tsit-tsui, tsit’tsit-tsui, tsui-tsui-tsui, tsit’tsit-tsui, tsit’tsit-tsui, tsui-tsui...”, lasting 3–4 seconds, and repeated several times in succession (often transcribed as “sweepy-swee-seepy” or “sweepy-svip-svip-svip”).

Habitat. In India found in fairly open deciduous forest of acacia (*Acacia*), teak (*Tectona*) etc., also in well-wooded country and mango groves; favours mature trees with deep-fissured bark. In plains

and hills. In W Africa principally in mature, open *Isobertia* woodland and in S tropics in rather similar mature miombo (*Brachystegia*) woodland, favouring well-developed stands of rough-barked species (e.g. *Brachystegia spiciformis*) with canopy of 10–15 m, but in Ethiopia occurs in evergreen juniper (*Juniperus*) forest although recorded also in acacias; apart from these broad preferences, recorded also in orchard-bush savanna in Nigeria, *Terminalia macroptera*–*Pseudocedrela kotschy* savanna woodland in Central African Republic, open wooded areas (especially with acacia) in Kenya, *Cryptosepalum* forest (mavunda) in Zambia, gallery woodland in Angola, and open stands of *Terminalia sericea* in Malawi, where occurs also in the *Brachystegia*/riparian-forest ecotone, exceptionally in evergreen forest up to 5 km from nearest *Brachystegia*. Recorded to at least 760 m in Sierra Leone, to at least 1350 m in Nigeria, at 1000–2300 m in Kenya, above 1500 m in Ethiopia, at 1250–1380 m in SE DR Congo, and at 915–1525 m (occasionally 305–1675 m) in Malawi.

Food and Feeding. Food insects, including moths and caterpillars (Lepidoptera), beetles (Coleoptera) and bugs (Hemiptera), also spiders (Araneae). Forages on trunks and larger branches of trees, starting near base and working upwards, then moving to base of next tree; may also search horizontal branches. Holds tail away from bark as it moves, thus resembling a nuthatch (*Sitta*), and may cling to branches upside-down. Sometimes forms small flocks in non-breeding season in India; in Africa often joins mixed-species foraging parties, and up to ten individuals recorded in such flocks in Zimbabwe.

Breeding. Season Feb–May in India; Jan in Ghana, Apr (and possibly Mar) in Ethiopia, May and Dec in Kenya/Uganda, Nov in Tanzania; Aug–Sept in Angola, Oct–Dec in NE DR Congo and Aug–Oct and Feb–Mar in S; Sept in Zambia, Sept–Oct in Malawi, and Aug–Oct (peak Sept) in Zimbabwe. Nest a neat, deep cup constructed from flower and leaf stalks, rootlets and bark chips, cemented on outside with spider webs, insect cocoons, caterpillar excreta and vegetable down, covered with lichen, and lined with spider webs and egg sacs, cocoons and plant down, external diameter c. 60–70 mm, internal diameter c. 45 mm, depth of cup c. 45 mm, wall c. 12 mm thick; placed 3–12 m above ground in tree fork, often where horizontal branch joins main trunk and where a knot or other protuberance breaks up outline; superbly camouflaged and extremely hard to find. Clutch 1–3 eggs (usually 2 in India, 3 in S Africa), in India pale grey or greenish-grey with dark brown specks and paler secondary blotches, especially at larger end, c. 19 × 13 mm, in Africa pale turquoise-blue, bluish-green or pale green with grey or lavender undermarkings and irregular black and brown spots, often concentrated at broader end, average 18.3 × 13.3 mm; incubation by female, fed on nest by male, she often sits with bill pointing upwards and gives high-pitched twittering call to maintain contact with male (usually feeding nearby); chicks brooded and fed by both parents; no information on duration of incubation and nestling periods.

Movements. Essentially resident, but some seasonal movements thought to take place in Africa. A scatter of records away from core breeding areas may represent vagrants and wanderers but, in less well-watched areas, could possibly indicate local breeding populations (the species is notoriously elusive). Thus, reported SE Senegal (one record, Niokolo-Koba National Park), Gambia (three records), Guinea-Bissau (three or more records), NW Guinea (one old record), Togo (one record), Botswana (one record, Kasane) and NE South Africa (one old record, Kruger National Park).

Status and Conservation. Not globally threatened. Rather scarce and local in India. In W Africa generally rather scarce and local, although may be frequent in NW Sierra Leone and N Ivory Coast; uncommon to locally frequent in Ethiopia, but scarce or rare and local in S Sudan, NE DR Congo, Uganda and Kenya; rather commoner in S tropics, where common in Angola in N Huila (although rare in Congo Basin), quite common in Zambia (scarcer in drier woodland), not uncommon in Malawi W of Rift Valley (scarcer elsewhere) and locally common in Tanzania; sparse and local in Zimbabwe. Often shy and elusive; easily overlooked and may be commoner in areas of suitable habitat than records suggest. Throughout range, this species’ requirement for large trees means that habitat loss and degradation have undoubtedly caused some decline in recent decades; in Kenya extirpated from most areas as a result of these factors and now confined to Kapenguria region, and no recent records from Uganda. Occurs in several protected areas: in India, for example, probably breeds in Kawal Wildlife Sanctuary, in Andhra Pradesh, and rare in Keoladeo Ghana (Bharatpur) National Park, in Rajasthan; in Africa, present in e.g. Comoé National Park, in Ivory Coast, Bénoué National Park, in Cameroon, and Dzalanyama Reserve, in Malawi.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family RHABDORNITHIDAE (RHABDORNIS)

- Medium-small passerines with moderately long, strong bill; mostly brown above, pale below with distinctive streaking, and dark face mask.
- 15–19 cm.

- Philippines.
- Forest edge, and secondary and primary forests.
- 1 genus, 3 species, 7 taxa.
- No species threatened; none extinct since 1600.

Systematics

The family Rhabdornithidae is one of several poorly known, enigmatic avian groups found exclusively within the Philippine Archipelago. It contains a single genus, *Rhabdornis*. Its members receive this same name, “rhabdornis”, as their normal English vernacular name, which is treated as invariable in singular and plural. Rhabdornis have several superficial similarities to the treecreepers (Certhiidae) and the Australasian treecreepers (Climacteridae), and the genus was placed in the family Certhiidae by R. B. Sharpe in volume four of his *Handlist of the Genera and Species of Birds*, published in 1903 by the British Museum (Natural History). This treatment was followed by R. C. McGregor, the foremost ornithologist in the Philippines during the first half of the twentieth century, in the passerine volume of his 1909 tome *A Manual of Philippine Birds*, published by the Bureau of Science, in Manila. It was continued by J. Delacour in his section of the book *Birds of the Philippines*, co-authored with E. Mayr in 1946. Being the eminent systematist that he was, however, Delacour did comment that rhabdornis are “very aberrant and recall only vaguely the familiar North American and European birds [genus *Certhia*], being more closely like the Australian creepers (genus *Climacteris*)”.

In 1967, J. C. Greenway, in volume 12 of J. L. Peters’s *Checklist of Birds of the World*, elevated the taxonomic status of rhabdornis to that of a family, the Rhabdornithidae. He remarked that “The relationships of this taxon [Rhabdornithidae] are obscure.” A colleague of both Delacour’s and Mayr’s, Greenway probably had many conversations about this “obscure” taxon that led him to place the family between Certhiidae and Climacteridae, all of which followed the nuthatches (Sittidae) in sequence. Four years later, in his landmark book *Philippine Birds*, J. E. duPont pulled together all that was known with regard to the systematics of Philippine birds and, for the first time, had them illustrated in full colour. He apparently saw the similarities of rhabdornis with the *Ptilocichla* ground-babblers and placed the family between Sittidae and Timaliidae. The divergence away from the creepers was supported by R. Orenstein in his PhD thesis for the University of Michigan, entitled “Morphological adaptations for bark-foraging in the Australian Treecreepers (Aves: Climacteridae)”; Orenstein found that rhabdornis differs from both Certhiidae and Climacteridae in leg musculature and in the lack of such adaptations for climbing and creeping as stiffened tail feathers, elongated toes and reduced toe pads. In 1985, he and R. S. Kennedy,

in the section on “Philippine creepers” in *A Dictionary of Birds*, edited by B. Campbell and E. Lack, point out that rhabdornis have “plumage and anatomical similarities to the babblers *Ptilocichla* and *Kenopia*...”.

The duPont sequence was followed by K. C. Parkes in 1973, by E. Dickinson, Kennedy and Parkes in 1991, and by Kennedy and colleagues in 2000. On the other hand, C. G. Sibley and B. L. Monroe, in their monumental 1990 work *Distribution and Taxonomy of Birds of the World*, tentatively placed rhabdornis in a greatly enlarged family Sylviidae, where they were incorporated after the parrotbills (*Paradoxornis*) at the end of a babbler tribe “Timaliini”. This arrangement was followed by T. Inskipp, N. Lindsey and W. Duckworth in 1996.

These attempts to determine the true relationships of *Rhabdornis* were made in the absence of tissue or blood samples, which, had they been available, would have enabled molecular investigations to be conducted. The obtaining of tissue, however, has not been an easy task. During the period from the late 1940s through to the early 1970s, hundreds of specimens were obtained by D. Rabor and collectors from the Philippine National Museum, and there is, therefore, excellent comparative material which can be utilized as a means of examining rhabdornis by traditional morphological methods. Recent specimen-collectors from the Field Museum of Natural History, in Chicago, the Cincinnati Museum of Natural History, in Ohio, and the US National Museum, in Washington, as well as local ones from the Philippine National Museum, have in most cases used mist-nets or single-shot pellet guns as their collecting tools. Rhabdornis tend, however, to inhabit the upper and middle levels of the canopy (see Habitat), and the traditional mist-net set from the ground to 2.5 m above ground has been virtually useless in catching these birds. Special efforts to raise nets higher in the canopy in front of fruiting and flowering trees have yielded mixed results, and then, of course, the teams need liquid nitrogen, certain buffers or alcohol to obtain suitable tissue for DNA analysis.

Despite the problems, *Rhabdornis* tissue has finally been obtained, it has been possible to examine the molecular genetics of this family, and some of the initial results of analyses appear, at least on the surface, quite startling. The big surprise is the suggestion, based on nuclear RAG-1 gene research undertaken by A. Cibois and J. Cracraft, and published in *Molecular Phylogenetics and Evolution* in 2004, that rhabdornis may belong in the superfamily Muscicapoidae, positioned after the mockingbirds (Mimidae) and before, or even within, the starling family

Rhabdornithidae comprises three rather similar species in a single genus (*Rhabdornis*) endemic to the Philippines. Smallish to medium-sized, rather front-loaded passerines, they have relatively long, pointed wings and a short, square-tipped tail. The bill is rather long and slender, with a slightly decurved culmen.

The **Stripe-headed *Rhabdornis*** gets its English name from the white streaks on its otherwise dark brown crown, a feature that quickly distinguishes it from its congeners.

(Sturnidae). The suggested relationship between the rhabdornis and the starlings did not, however, have strong statistical support. On the other hand, a more recent study, carried out by D. Zuccon and colleagues, using both nuclear and mitochondrial genes, suggested that not only is *Rhabdornis* closely related to Sturnidae, but it is also belonged within the starling group. These later findings, published in the same journal in 2006, indicated also that the oxpeckers (*Buphagus*), long considered closely related to starlings, are basal to the whole starling assemblage. Although the relationship of rhabdornis, starlings and *Buphagus* was unexpected, all of these species share the habit of nesting in holes in trees.

The rhabdornis' brush-tipped tongue, on which J. Whitehead commented in 1899 (see Morphological Aspects), is a character that would not normally place these birds among the starlings. This feature, however, must represent a derived character, perhaps an adaptation for exploiting the nectar of flowers, or for other unknown purposes. In 2000, Kennedy and colleagues, in putting to rest the long overused vernacular name of "creeper", stated that the rhabdornis rarely creep but that, rather, they hop along and between branches, gleaning insects from beneath the bark and leaves. This type of foraging behaviour is not unlike that employed by glossy starlings of the genus *Aplonis*. Thus, the rhabdornis may well represent an early lineage among starlings, one with morphologically unique adaptations that were unrecognized by earlier investigators.

With regard to the origin of rhabdornis, the best inference can be obtained by looking at the origin of starlings. Cibois and Cracraft support an Old World origin for the sturnids. Divergence-dating calculated on the basis of a "molecular clock" suggested that the rhabdornis separated from the other major lineages of starlings, namely an Oriental-Australasian clade (including the genera *Sarcops* and *Aplonis*), and an Afrotropical-Palearctic clade (including *Sturnus* and *Acridotheres*), at a point some 18–20 million years ago. The only large island present at that time in what is now known as the Philippines would have been the northern part of Luzon, which originated over 25 million years ago. Mindoro arose *de novo* as an oceanic island around 8–10 million years ago, but *Rhabdornis* has not been found there, and it probably never successfully colonized the island.

Alignment of RAG-1 gene sequences from GenBank, a massive open-access database containing all publicly available nucleotide sequences, indicated that the Stripe-headed Rhabdornis (*Rhabdornis mystacalis*) and the Stripe-breasted Rhabdornis (*Rhabdornis inornatus*) differ by 1.0%, a considerably large divergence for putatively closely related species. Using the rate cali-

bration for passerines of 0.13% divergence per million years for RAG-1 gene sequence, as estimated by J. G. Groth and G. F. Barrowclough, it can be calculated that these two rhabdornis species diverged 7.7 million years ago. This estimated timing predates the emergence and geological upliftment of other large islands of the central and southern Philippines during the last 2–5 million years, the Pliocene and Pleistocene periods. This divergence among the founder population may have taken place on the island of Luzon, the oldest land formation in the archipelago, with later colonization of other islands towards the south soon after their emergence from the ocean floor. This estimate, however, remains tentative, and may well change as more refined models of molecular clocks are devised. One unique feature revealed by the sequence alignment of *R. mystacalis* with other muscicapoids is the deletion of one amino acid, glutamine. Insertion or deletion of amino acid in nuclear protein-coding genes such as RAG-1 is a rare event, even for non-sibling species, and can be considered a useful marker to delineate higher-level groupings.

Although Rhabdornithidae appears not to be so highly speciose as other families within the Muscicapidae, the early split of the lineage from Sturnidae, and its many novel features, would seem sufficient to warrant retention of the group as a separate family until more data on its evolution and biology have been gathered, and until a clearer resolution of the whole oscine phylogeny has been found. In this connection, it is interesting to note that in the most recent edition of *The Howard and Moore Complete Checklist of the Birds of the World*, published in 2003, the editor has retained the family Rhabdornithidae and placed it between the Mimidae and the Sturnidae. Whether this phylogenetic position will hold for this endemic Philippine family of birds, which various authors have described as being "aberrant", "very aberrant" and "obscure", is dependent on future developments in the field of molecular systematics.

Turning to the genus itself, the number of species of rhabdornis that have been accepted by ornithologists has varied over the years. In the nineteenth century, it was typical of taxonomists of the time to accord full species status to each new bird population discovered that was in any way different from another. In 1909, McGregor reported three species, *R. mystacalis*, *R. minor* and *R. inornatus*. In 1911, he offered the name *R. longirostris* for a potential fourth species, this based on one specimen from Negros which had a longer bill and larger feet than individuals of *R. mystacalis* from Luzon. With the rise of the subspecies concept in the middle of the twentieth century, the various taxa were "lumped" into two distinctive species, *R.*

The **Stripe-breasted Rhabdornis** is very similar in plumage to the **Grand Rhabdornis** (*Rhabdornis grandis*); while current taxonomy lists them as separate species on the basis of different body, bill and tail lengths, the validity of this treatment is under review. Although rhabdornis have been considered closely related to the treecreepers (*Certhiidae*), to the extent of being grouped within that family, they lack morphological adaptations, such as stiffened rectrices or long claws, that would enable them to ascend tree trunks and thereby favour such a taxonomic relationship.

[*Rhabdornis inornatus alaris*,

mystacalis and *R. inornatus*, and most subsequently discovered taxa were described as subspecies of one or the other of these two. The result was that *R. mystacalis* included subspecies *minor* and *longirostris*, as well as the nominate race, and *R. inornatus* incorporated the nominate race and the new subspecies *leytensis*, *alaris*, *zamboanga* and *abori*. In 1952, however, F. Salomonsen described a new species, similar to *R. inornatus* but decidedly larger in all body measurements, most prominently in the bill. He named it *R. longirostris*, unaware that the name was preoccupied by McGregor's "species", and in 1953 he renamed it as *R. grandis*. Fourteen years later, Greenway, in Peters's *Check-list of Birds of the World*, concluded that *grandis* should be a subspecies of *R. inornatus*, a treatment followed by duPont in 1971 in his *Philippine Birds*. Salomonsen, however, was not happy about this, and in his 1973 review of duPont's book, in *The Auk*, he stated "I do not agree that *Rhabdornis grandis* is a geographical race of *R. inornatus* as it differs so remarkably in size, the long tail, the long curved bill, etc."

So, are there two, three or more species of rhabdornis? Dickinson and colleagues, in their 1991 checklist of Philippine birds, followed Salomonsen in recognizing the Grand Rhabdornis (*Rhabdornis grandis*) as a full species, a decision based on examination by Kennedy of the two specimens available at that time. This treatment was followed by many subsequent authors, in particular by Inskipp and colleagues in 1996 and by Kennedy and co-authors in 2000. This, however, is certainly not the end of the story. Dickinson examined the type specimen of *R. grandis*, and concluded that it was merely a larger subspecies of *R. inornatus*; this explains the note regarding an expected taxonomic review of the genus *Rhabdornis* in Kennedy and colleagues' *A Guide to the Birds of the Philippines*, of which Dickinson was one of the five authors. It is not surprising, therefore, that Dickinson, in his role as editor of the third edition of *The Howard and Moore Complete Checklist*, preferred to treat *grandis* as a subspecies of the Stripe-breasted Rhabdornis.

For the time being, it seems better to continue to recognize three species of rhabdornis, partially for reasons of conservatism but, more importantly, because a major review is currently underway. It is hoped that this study, which is being undertaken by Kennedy, H. Miranda and A. Jones, will clarify the taxonomy of *Rhabdornis* in respect of the number of valid species that it contains, whether it be two or three or, perhaps, even as many as

five. The Stripe-breasted and Grand Rhabdornis can be considered to form a superspecies, and it seems most unlikely that the Stripe-headed Rhabdornis consists of anything more than a single superspecies, if that.

Morphological Aspects

Rhabdornis are medium-sized to rather small passerines. The smallest is the subspecies *minor* of the Stripe-headed Rhabdornis, with an overall length of about 15 cm, whereas the largest, the Grand Rhabdornis, has an average length of about 17 cm. They are generally brown or greyish-brown above and white below, and all three species have a dark blackish-brown to greyish-brown facial mask bordered to a greater or lesser extent by white. In 1909, McGregor aptly described the salient morphological aspects of *Rhabdornis*, and the following is a paraphrasing of his words. All three of the species have wings of moderate length and somewhat pointed. The first, outermost, primary is narrow and short, being less than one-third the length of the second, which is almost as long as the third; the fourth and fifth primaries are the longest and are almost equal in length. The tail is square-ended and short, its length little more than half the width of the wing. The moderately long bill is gently curved, slender, and distinctly compressed laterally beyond the nostril. It has a hint of a notch in the cutting edge near the tip, and a distinct ridge along the culmen; the nostril is linear, exposed, and with an overhanging operculum. There are only a few rictal bristles, and these are very short. Frontal bristles are lacking, but several long backward-pointing hairs are present among the feathers of the forehead. The tarsus is equal to or shorter than the length of the middle toe with claw, and longer than the distance from the nostril to the bill tip; it is holothecal, the divisions between the scutes being obsolete.

The Stripe-headed Rhabdornis is easily distinguished from the other two species by the presence of white shaft streaks bordered by black on the otherwise brown crown and nape, and by the pure white breast and belly, with bold clear black and white streaks on the sides or flanks. The Stripe-breasted and Grand Rhabdornis lack white streaking on the head, and have greyish-white underparts with less bold streaks on both the breast and the flanks. A. Rand and Rabor, in 1960, and Parkes, eleven years

later, commented on the uniformity of the colour characteristics within and between subspecies of the Stripe-headed Rhabdornis. Examination of representatives of each population from northern Luzon south to Basilan corroborates these authors' statements.

Among the taxa included in the Stripe-breasted and Grand Rhabdornis, there are only slight differences in plumage colour. All geographical populations have varying amounts of white streaking on the hindneck, forming a collar; in the Stripe-breasted Rhabdornis, the nominate race and *leytensis* have the most white and the southern subspecies *alaris* has the least. With the exception of the last-named taxon, all populations of these two species have white spots on the lesser and median upperwing-coverts. The white spots on the hindneck, the side of neck and the wing-coverts of *inornatus* and *leytensis* make these two subspecies the most decorated of all taxa within the *R. inornatus* superspecies.

Bill length or culmen length in this genus is very interesting, and is one of the key attributes that helps to separate species and subspecies. Salomonsen, when first describing *R. grandis*, pointed out that the two "superspecies" (see Systematics) that co-exist in the eastern Philippine Islands, from Luzon south to Mindanao, exhibit a parallel development in bill length. On Luzon, the bill of the nominate race of the Stripe-headed Rhabdornis and that of the Grand Rhabdornis average almost the same size, 26 mm and 25 mm, respectively, while on Mindanao the race *minor* of the Stripe-headed Rhabdornis and subspecies *alaris* of the Stripe-breasted Rhabdornis have smaller but similar-sized bills measuring 21 mm and 20 mm, respectively. This pattern does not hold, however, in the west-central Philippines: on Panay and Negros, the nominate race of the Stripe-headed Rhabdornis has a bill length of 26 mm or more, whereas race *rabori* of the Stripe-breasted Rhabdornis has a bill about 20 mm long.

In 1899, Whitehead described the tongue of the Stripe-headed Rhabdornis as being "brush-tipped", and added that it was similar to that of other insectivorous birds that feed among flowers. Recent examination of the tongue of two specimens of this rhabdornis in the Delaware Museum of Natural History, in the USA, revealed that there are two ribbon-like projections extending from the tip of the tongue. Each of these projections is about 2.5 mm long, is 0.5 mm wide at the base, and tapers from the base to a point at the tip.

For the most part, rhabdornis show very little difference between the sexes. In general, females are slightly smaller than males, and are browner on the crown and face mask than males.

Recently fledged rhabdornis are very similar to adults but tend to be lighter brown, with less distinct striping.

As mentioned previously, rhabdornis do not possess any of the specialized morphological features, such as stiffened tail feathers or long claws, that would support their description as "creeping" birds. Their wings have no significant modifications for specialized flight. On the other hand, they do have fairly large, strong legs and feet that are well suited for hopping among branches of trees, and also for hanging from outer branches when securing small fruits and insects (see Food and Feeding).

Habitat

Rhabdornis live in both primary forest and secondary forest, and forest edge, from the lowlands to the montane zone, ascending to about 1750 m. They do not hesitate to fly across clearings or valleys, and they will forage in individual isolated trees when in clearings. They prefer the canopy and middle storey of the forest, and rarely come down to within a metre or so of the ground.

Generally, the Stripe-breasted and Grand Rhabdornis are altitudinally segregated from the Stripe-headed Rhabdornis. This is particularly true of populations of each group on Luzon, Mindanao and Negros, where the subspecies of the first two rarely occur below 800 m and those of the Stripe-headed Rhabdornis rarely exceed 1000 m. On Samar, Leyte, Biliran and Panay the Stripe-breasted Rhabdornis ranges down to lower elevations, presumably because there is very little higher-elevation forest remaining for the species on these islands. The lowest elevation recorded for the subspecies *leytensis* is at 230 m in the foothills of Mount Lobi, in central Leyte, where two specimens were obtained in May and June of 1964. The Stripe-breasted and Stripe-headed Rhabdornis thus overlap altitudinally on these islands. The Stripe-breasted Rhabdornis superspecies has not been found on Catanduanes, Masbate, Bohol, Calicoan, Dinagat and Basilan, which are relatively flat islands and do not therefore offer the altitudinal structure required to support more than one species; the Stripe-headed Rhabdornis is the only member of the family living on these islands.

General Habits

As with all other areas of their life, the habits of the rhabdornis are very poorly known. They are very active birds, usually travelling in single-species flocks or joining mixed flocks containing such species as the Elegant Tit (*Periparus elegans*), the Sulphur-billed Nuthatch (*Sitta oenochlamys*), fantails (*Rhipidura*) and leaf-warblers (*Phylloscopus*). The Stripe-headed Rhabdornis tends to travel in larger groups of up to 20 or so individuals, while the other two species normally move in smaller groups of ten or fewer. They hop and jump among main tree branches as they proceed towards the smaller outer branches. They do not creep, despite the earlier English name of "Philippine creepers", which indicates that such behaviour was widely suspected, but they do walk along branches. D. Amadon and S. G. Jewett, in their 1946 paper, were the first to mention that rhabdornis do not creep; these authors wrote that, rather, the bird "hopped briefly into view" and that they "saw no signs of creeping in the manner of *Certhia*".

When perched, rhabdornis tend to sit upright and perpendicular to branches. They usually sit in this manner on smaller branches, even on the tops of branches in dead trees. Periods of sitting are normally short, lasting for a few seconds, but longer sessions of 15–20 seconds are not uncommon, and there is at least one record of an individual sitting motionless for over one minute.

Rhabdornis have an undulating flight, with shallow wingbeats at the bottom of the undulation. They will often cover distances of 200 m or more in flight, before alighting again.

In the evening, at twilight, as many as several hundred rhabdornis have been seen to fly in to roost trees in clearings in the forest. This has been observed on several occasions, particularly in the forests of eastern Mindanao. One such event was recorded in detail in Kennedy's field notes of 3rd October 1982.

While the rhabdornis constitute a poorly known family, the paucity of information regarding the three species' vocalizations appears to be as much due to their taciturn nature as to inadequate research. The genus is not known to sing, and the main calls, given while foraging or perched, are relatively unremarkable, quiet, short and high-pitched notes, often given in succession. Sometimes breaking with this pattern, the **Stripe-headed Rhabdornis** also gives an explosive note amidst a more expansive, but otherwise barely audible, four-note series.

[*Rhabdornis mystacalis*
mystacalis,
Mt Maliking, Luzon,
Philippines.
Photo: Ketil Knudsen]

At 17:00 hours, near a quarry at an elevation of about 760 m, a flock of 30–50 rhabdornis, believed all to be Stripe-breasted Rhabdornis, flew into the top of a 30-m tree isolated in a clearing; some began to sally out on the outer branches, appearing very nervous. Between 17:15 and 17:20 hours a further eight individuals flew in to the tree, followed by three more in the ensuing eight minutes; no rhabdornis left the tree. The birds arrived singly or in groups of two or three, from all directions, from the surrounding forest. By 17:30 there was little movement, and it was almost dark; all activity had ceased by 17:37 hours. All of the rhabdornis roosted within 60 cm of the outermost branches, and many within the top 30 cm. Observations ceased at 17:41, ten minutes before total darkness prevailed. This roosting behaviour is similar to that of the Short-tailed Starling (*Aplonis minor*) on Mindanao, but the latter usually ends up sleeping in nesting cavities at its breeding colonies.

Voice

There is little to be said about the vocalizations of the rhabdornis. They are essentially unmusical, high-pitched utterances, and consist of a rapid series of several similar-sounding notes, "tsee", "tzit" or "zeet", strung together. Series can contain four or more notes. Generally, the vocalizations of these birds are hardly audible, but some notes have been described as having an explosive quality.

Food and Feeding

Rhabdornis are opportunistic omnivores. They feed on insects, including caterpillars and the contents of cocoons, which they glean from beneath and on bark and among leaves and in flowers, and they consume seeds and fruits, which they obtain in the outer branches of trees. When travelling in flocks through the forest, they tend to feed more on insects.

When foraging in fruiting or flowering trees, they usually visit the trees singly or in small groups, and not in a flock. Here, they will approach from all directions. Having arrived in the tree, they then pluck fruits, usually pea-sized or smaller ones, while perched; alternatively, they sally out to the last limbs and pluck the fruit, and then either fly to a perch to consume the food or fly back in the direction from which they came. Whitehead was the first to describe the foraging behaviour of rhabdornis. In his 1899 "Field-Notes" published in *The Ibis*, he recorded that a feeding Stripe-headed Rhabdornis, which he watched in Isabella, on Luzon, reached forward among flowers, much in the same way as spiderhunters (*Arachnothera*). Rhabdornis also indulge in aerial flycatching, and they will chase insects that fly out while they are foraging. In addition, Kennedy and colleagues, in 2000, reported that on one occasion more than 100 Stripe-breasted Rhabdornis gathered at a site in eastern Mindanao in order to exploit "termites [Isoptera] or some other similar flying insect", which they caught by flycatching. They are known also to eat small vertebrates. For example, a Stripe-breasted Rhabdornis on Mindanao was once seen to consume a tree-frog.

In duPont and Rabor's 1973 paper on the birds of the island of Dinagat, Rabor describes the foraging habits of the race *minor* of the Stripe-headed Rhabdornis in some detail. He recorded that the bird went about its daily feeding activities usually singly or in pairs, "creeping on the trunks and branches of trees of moderate heights", and also that a pair was occasionally seen to feed at the ends of small branches. In this latter method of feeding, the pair alighted on small twigs nearest the leaves containing the food items in which the birds were interested; he remarked that, when they foraged in this manner, there was no creeping action at all but "the birds behaved like ordinary perching bird species". Rabor commented that, when the rhabdornis feeds on the flowers and fruits at the ends of twigs in the manner of other birds, it is possible that it does not need to creep, whereas, "when it is after insect food, it creeps and examines the branches and trunks for possible tidbits".

Rabor's observation describes fairly accurately the foraging behaviour of rhabdornis, with the exception of the "creeping" behaviour. As contended elsewhere (see Morphological Aspects, General Habits), rhabdornis, when actively foraging for insects, rarely creep. Rather, they jump, hop, run, walk and fly between branches while gleaning or probing, or they sally for insects at the end of branches among leaves, or they capture invertebrates by means of aerial flycatching.

Breeding

Very little is known about the breeding behaviour and biology of *Rhabdornis*. Whitehead, in his 1899 field notes, reported that one of his hunters had told him that he had shot a Stripe-headed Rhabdornis while it was building a nest in a hole in a tree.

More than 80 years later, in 1981, Kennedy observed a pair of Stripe-breasted Rhabdornis of the subspecies *leytensis* which was building a nest in the hole of tree on Biliran Island, north of Leyte. He watched the pair from 09:40 to 14:50 hours on 8th April and from 08:30 to 13:39 on 9th. A reforestation guard at the site, which was at an elevation of 600 m, identified the partially dead tree as being a binoloan (*Acmena acuminatissima*), a member of the family Myrtaceae. The tree was about 1 m in diameter at the base and about 20 m tall. It was located at the forest edge, 30 m below the crest of a ridge covered with cogon grass (*Imperata cylindrica*). The presumed nest-cavity was about 15 m from the ground, inside a knothole of 10–13 cm diameter located at an old junction of two large branches, with the main branch before the junction about 20–25 cm in diameter. The two birds collected four or five short sticks 5–8 cm in length, about the size of a toothpick, from the upper outer branches of the nest tree or from other forest trees up to 200 m away; in addition, they brought in two yellow-green red-stemmed leaves, each about 7 cm long, and a piece of shredded bark. All items were carried in the bill. On returning, the rhabdornis would usually land in the nesting tree before entering the nest-hole, but on two occasions they flew directly into the hole from adjacent areas. The time spent inside the nest-cavity by an individual varied from 10 seconds to as much as 6 minutes, and there were two occasions when both partners were in the nest-hole together for up to 2 minutes. Once, one of the rhabdornis emerged with a fluffy white object, possibly a down feather or spider webs, and proceeded to attach this to the upper rim of the nest-hole opening.

In their 1990 report on the birds of Mount Isarog National Park, in south-east Luzon, S. Goodman and P. Gonzales recorded that, on 29th February 1988, they had seen a Stripe-headed Rhabdornis as it entered an excavated hole in a tree, carrying food in its bill; the hole was about 5 m above the ground. Also, two nest cavities of the Grand Rhabdornis were recently found, in dead trees 10–15 m above the ground.

Except for the already mentioned dates for presumed active nesting, information on the timing of breeding of rhabdornis comes from data on the tags of scientific skins, or from specimens of what are obviously recently fledged individuals. If information exists on specimen labels, it usually includes details of gonad size, direct or estimated measurements indicating enlarged testes or an enlarged ovary, or the presence of an egg in the oviduct.

Timing of breeding appears to be similar for all rhabdornis. Most breeding activity begins in late March and continues through May to early June. "Egg about to be laid", or some similar statement, was written on labels of Rabor's specimens of Stripe-headed Rhabdornis; these were of the nominate race, from Mount Bulusan, in south-east Luzon, on 30th April, and of the subspecies *minor*, from Samar on 16th April and from Leyte on 30th May. Records of recently fledged young include, for the Stripe-breasted Rhabdornis, two in February, one in April and three in May, all of the subspecies *alaris*, with one of the nominate race in June and one of the subspecies *rabori* in April. For the Stripe-headed Rhabdornis, there are single records of recently fledged young of the nominate race in May and June, and singles of the subspecies *minor* in May and August. The August fledgling came from Mindanao, and was obtained by Governor C. Forbes in 1922. An-

For a family whose members are not particularly rare and occur on several major Philippine islands, it is curious that so little is known about rhabdornis breeding biology. There have been a few observations of birds, such as this **Stripe-headed Rhabdornis**, apparently nesting in cavities in tree trunks or branches. But what goes on inside the presumed nest-hole remains a mystery. There is no information at all for the family on nest structure or clutch size, the division of parental responsibilities or nestlings.

[*Rhabdornis mystacalis*
mystacalis,
Mt Maliking, Luzon,
Philippines.
Photo: Ketil Knudsen]

other "anomalous" date involved a male Stripe-breasted Rhabdornis of the race *leytensis*, which had enlarged testes in July.

It is not surprising that for so poorly known a family, there is no detailed information available on the nests themselves, nor, of course, on the eggs, the clutch size and the nestlings. The breeding biology of *Rhabdornis* remains unknown.

Movements

Rhabdornis are non-migratory, and there is no evidence to suggest that any of the species undertakes seasonal altitudinal movements. They do move through the forest in flocks, and they may make reasonably long flights to fruiting or flowering trees in search of food, but they are, within these constraints, essentially resident.

Relationship with Man

The members of this family eat seeds and fruits, and are likely, therefore, to be important in dispersing seeds throughout the forest. They consume insects in the forest and forest edge, but they have not been recorded entering agricultural fields or orchards. Any possible beneficial effects of rhabdornis as consumers of insects considered by humans to be injurious remain to be determined.

As this is a small family of three poorly known species, all confined to the Philippine Islands, it is a target avian group for both resident and visiting birdwatchers seeking to observe it in the field. Consequently, the rhabdornis have a moderate economic importance to the Philippines.

Status and Conservation

The three species of rhabdornis are considered to vary from uncommon to common, and none is listed in the Red Data Books. It is widely known, however, that the Philippines are undergoing an "ecological meltdown", as frequently noted by Miranda, and that the forests are retreating up the sides of mountains, leaving lowlands and foothills with mixed agriculture and cogon grasslands.

The loss of lowland forests poses a particular threat to the Stripe-headed Rhabdornis, since it is basically a lowland spe-

cies, rarely reaching above 1000 m. Although almost all of the islands of the Philippines are being denuded, Negros is probably in the worst condition of any of the larger islands where rhabdornis occur. Most of the forest below 1000 m is virtually gone on Negros. Moreover, in 1911, McGregor pointed out that a specimen of the Stripe-headed Rhabdornis from Negros had a much longer bill and larger feet than those of its counterparts on Luzon, and he remarked that, if this trait held in a series of specimens, the Negros population "may be known as *Rhabdornis longirostris*" (see Systematics). Some 50 years later, Rand and Rabor, with additional specimens to hand, agreed with McGregor and elevated the taxonomic status of the Negros population to that of a subspecies. This decision was reviewed in 1971 by Parkes, who did not concur with Rand and Rabor's conclusion, and "*longirostris*" has since been considered to be no more than a long-billed population of the nominate race of the Stripe-headed Rhabdornis, like the long-billed population in northern Luzon.

Be that as it may, rhabdornis do not fly long distances, and it is likely that the Negros birds, and probably the Panay ones, too, have been genetically isolated for at least the last 10,000 years since the Pleistocene. The point here is that at the species level, or even at the subspecies level as we now know them, no rhabdornis taxon is rare or threatened. Nevertheless, the final word on the systematics of this group is still to be written, and we should therefore consider each disjunct population as a discrete conservation unit. This applies whether populations are separated by water, as are those of the Stripe-headed Rhabdornis, or by lowlands and/or water, as are the populations of the two other species currently recognized.

PLATE 7

Family RHABDORNITHIDAE (RHABDORNIS) SPECIES ACCOUNTS

PLATE 7

Genus *RHABDORNIS* Reichenbach, 1853

1. Stripe-headed Rhabdornis

Rhabdornis mystacalis

French: Rhabdornis à tête striée

Spanish: Rhabdornis Común

German: Streifenkopf-Trugbaumläufer

Other common names: Stripe-headed Creeper, Stripe-sided Rhabdornis

Taxonomy. *Meliphaga mystacalis* Temminck, 1825, neighbourhood of Manila, Luzon, Philippines. Proposed race *longirostris* (from vicinity of Cadiz, in N Negros) described on basis of long bill, but bill length evidently no different from that of birds of nominate race from N Luzon. Two subspecies currently recognized.

Subspecies and Distribution.

R. m. mystacalis (Temminck, 1825) – N & WC Philippines (islands of Luzon, Catanduanes, Masbate, Panay and Negros).

R. m. minor Ogilvie-Grant, 1896 – Samar, Biliran, Leyte, Bohol, Calicoan, Dinagat, Mindanao and Basilan, in EC & S Philippines.

Descriptive notes. 15.1–17.5 cm; 22.4–31.5 g. Male nominate race has crown and nape dark brownish-black, feather centres white (forming bold white streaks); upperparts dark brown, becoming redder towards rump, mantle feathers with conspicuous white shaft streaks continuing from streaks on hindneck and becoming inconspicuous towards lower back; upperwing and tail dark brown; broad facial mask from lores and extending to nape dark brown to black, bordered by narrow white eyebrow; throat and centre of breast and belly pure white, feathers of side of breast, flanks and undertail-coverts with bold white centres bordered by dark brown and black (forming broad stripes); iris dark brown; bill black or dark horn; legs dark horn. Female differs from male in having lighter brown crown and facial mask. Immature is similar to adult but browner above, including mask, with less conspicuous streaks on head and mantle, has buff-white underparts with streaks on flanks less contrasting. Race *minor* is similar to nominate in plumage but distinctly smaller, with shorter bill (20 mm, compared with 25 mm of nominate). Voice. Calls during foraging and when perched a series of “zeet” notes. Also recorded is an unmusical high-pitched “tsee tsee wick-tsee”, first notes hardly audible, followed by explosive “wick” syllable of last phrase.

Habitat. From virgin forest to forest edge and clearings, from sea-level to 1000 m, rarely higher.

Food and Feeding. Varied diet, including insects (e.g. caterpillars), and fruits and seeds. Forages in flocks of up to 20 or more individuals, moving rapidly through canopy and middle storey and gleaning insects from beneath bark and under leaves. Also joins mixed-species feeding flocks, especially those with Elegant Tit (*Periparus elegans*); one such flock joined by present species on Luzon consisted also of Philippine Woodpecker (*Dendrocopos maculatus*), several Philippine Orioles (*Oriolus steerii*), a number of Blackish Cuckoo-shrikes (*Coracina coerulescens*) and several small leaf-warblers (*Phylloscopus*). Will travel several hundred metres to a flowering or fruiting tree, arriving singly or in small groups; plucks seeds and fruits from outer branches by sallying out and hovering momentarily under those branches.

Breeding. On basis mainly of data on gonad condition of specimens, most breeding activity from Mar, or perhaps Feb, to Jun or early Jul; oviduct eggs in mid-Apr on Samar and end May on Leyte; recently fledged young 28th Apr to 9th Aug. Apparently nests in tree cavity. No other information.

Movements. Resident. Only local foraging movements documented.

Status and Conservation. Not globally threatened. Fairly common throughout range. Presence on Biliran known only from sight record. Forests below 1000 m are rapidly disappearing throughout Philippines, putting this lowland and middle-elevation species at possible risk; Negros population likely to be the first in danger, as almost all lower-elevation forests on that island have already been destroyed. Present but relatively rare in Rajah Sikatuna National Park, on Bohol.

Bibliography. Amadon & Jewett (1946), Brooks *et al.* (1996), Delacour & Mayr (1946), Dickinson *et al.* (1991), Gilliard (1950a), Goodman & Gonzales (1990), Kennedy *et al.* (2000), McGregor (1909, 1911), Meyer de Schauensee & duPont (1962), Ogilvie-Grant (1896b, 1897a, 1897b), Orenstein & Kennedy (1985), Parkes (1971, 1973), duPont (1971b), duPont & Rabor (1973b), Rand (1970), Rand & Rabor (1960), Salomonsen (1952), Whitehead (1899), Worcester & Bourns (1898), Zuccon *et al.* (2006).

2. Grand Rhabdornis

Rhabdornis grandis

French: Rhabdornis à long bec

Spanish: Rhabdornis Grande

German: Langschnabel-Trugbaumläufer

Other common names: Long-billed Rhabdornis/Creeper

Taxonomy. *Rhabdornis grandis* Salomonsen, 1953, Kainay, Abra Province, Luzon, Philippines. Originally described under the name *longirostris*, but that name invalid, as preoccupied. Forms a superspecies with *R. inornatus* and often considered conspecific, but differs somewhat in size and proportions; taxonomic review currently in progress. Monotypic.

Distribution. Cordillera Mts and Sierra Madre of N & NC Luzon, in N Philippines.

Descriptive notes. 16.3–18 cm; 45–46 g. Male has crown dark grey, feathers with darker grey to black tips; hindneck grey, leading to brown on back (with very faint shaft streaks), rump reddish-brown; lesser upperwing-coverts with conspicuous white shaft streaks and/or spots bordered by dark brown, primaries dark brown, secondaries reddish-brown; tail dark brown; blackish-brown mask from lores to nape, bordered above by white supraocular stripe and below by indistinct white malar stripe; black spots on side of neck behind mask; throat light grey; upper breast mottled grey and white, some black spots continuing from side of neck;

side and flank feathers greyish-white, reddish-brown margins forming streaks that fade into side of breast; belly dirty white, undertail-coverts as flanks; iris brown; bill black or dark horn; legs brownish-grey. Female is similar to male in plumage, but slightly smaller. Immature plumage undescribed; thought to be similar to adult. Voice. Calls described as quiet high-pitched “zip zip zeet zip”; some notes have short trill-like quality, “zrrrrt”.

Habitat. Middle-elevation and higher-elevation primary and secondary dipterocarp and hardwood forests, including logged forest. Not known from high-elevation pine (*Pinus*) forest, but likely to occur in mixed pine and hardwood forests.

Food and Feeding. Varied diet, including insects, seeds and fruits; green seeds and fleshy fruits found in stomachs. Found singly and in small groups, also in mixed-species flocks. Group of six individuals observed while foraging in crown of isolated tree along logging road at 700 m in Sierra Madre (in Cagayan Province); arrived at fruiting tree one or two at a time, flying across a valley from adjacent forests; same tree attracted several Philippine Hanging-parrots (*Loriculus philippensis*), Buzzing Flowerpecker (*Dicaeum hypoleucum*) and also *R. mystacalis*.

Breeding. Both male and female specimens had brood patches and enlarged gonads in early May. Two nest-holes were 10–15 m up in dead trees; bark strips seen being brought as nest material. No other information.

Movements. No movements known.

Status and Conservation. Not globally threatened. Restricted-range species: present in Luzon EBA. Generally uncommon and local; locally rather common in Sierra Madre, which is probably the species' only real stronghold. Main threat is large-scale deforestation, occurring throughout its range. Apparent ability to survive in secondary forest, however, suggests that it is moderately secure.

Bibliography. Dickinson *et al.* (1991), Kennedy *et al.* (2000), Mayr (1957), duPont (1971b), Poulsen (1995), Rand (1970), Rand & Rabor (1960), Salomonsen (1952, 1953a, 1973).

3. Stripe-breasted Rhabdornis

Rhabdornis inornatus

French: Rhabdornis à tête brune **Spanish:** Rabdornis Cabecipardo
German: Braunkopf-Trugbaumläufer
Other common names: Plain-headed/Stripe-breasted Creeper

Taxonomy. *Rhabdornis inornatus* Ogilvie-Grant, 1896, Samar, Philippines. Forms a superspecies with *R. grandis* and often considered conspecific, but differs somewhat in size and proportions; taxonomic review currently in progress. Proposed race *zamboanga*, described from Masawan, on Mt Malindang (E Zamboanga Peninsula), in W Mindanao, treated as synonym of *alaris*. Four subspecies currently recognized.

Subspecies and Distribution.

R. i. rabori Rand, 1950 – Panay and Negros, in WC Philippines.
R. i. leytenensis Parkes, 1973 – Biliran and Leyte, in EC Philippines.
R. i. inornatus Ogilvie-Grant, 1896 – Samar, in EC Philippines.
R. i. alaris Rand, 1948 – Mindanao, in S Philippines.

centres (contributing to necklace); throat mottled dirty white and grey; flank feathers white bor-

Descriptive notes. 15.2–18.8 cm; 35–40 g (excluding *rabori*). Male nominate race has crown brownish-grey with slightly darker feather edges, hindneck brown with prominent white shaft streaks (forming decorative necklace); back brown with faint shaft streaks, rump redder with very faint streaks; lesser upperwing-coverts with conspicuous white shaft streaks or spots, primaries dark brown, secondaries brown; tail dark brown; dark brown mask from lores to hindneck, bordered above by supra-ocular line of white feathers with dark brown margins and below by whitish malar, neck behind mask with dark brown feathers with white

dered by reddish-brown (giving striped appearance), pattern fading into breast, centre of breast and belly dirty white, undertail-coverts similar to flanks but with striping less clearly defined; iris dark brown; bill black; legs dark horn. Female is similar to male but lighter brown, including on mask. Immature is browner above than adult, underparts heavily streaked and washed with buff. Races differ mainly in presence or absence of decorative collar and white spots on lesser wing-coverts: *leytenensis* is very similar to nominate, but crown greyer; *alaris* lacks collar and lacks white shaft streaks/spots on lesser coverts; *rabori* is larger than others, with greyer crown, face mask and throat, and inconspicuous shaft streaks on hindneck. **Voice.** Calls described as a high-pitched "tzit", repeated often, sometimes in rapid series as "tzit tzit tzit tzit".

Habitat. Usually in submontane and montane forests above 800 m, up to 1750 m; on Samar, Leyte, Biliran and E Mindanao ranges lower, down to 500 m or below, lowest records two specimens at 230 m in foothills of Mt Lobi (Leyte). Apparently prefers canopy of tall dipterocarp trees and the transition zone between dipterocarp and mid-mountain forest types on Mt Malindang, in W Mindanao. Uses forest edge and second growth, and crosses clearings to reach isolated fruiting trees.

Food and Feeding. Opportunistic, eating a wide range of items including insects, and seeds and fruits, and once a small tree-frog; seen to eat small pea-sized (c. 5 mm) red berries on Mindanao. One individual attempted to eat contents of a cocoon, but without success. Tends to stay in upper and middle canopy of forest, and rarely seen near ground, but does not hesitate to perch openly on dead branches. Forages in small groups of up to ten individuals, and will join mixed-species flocks; will gather in large numbers at times when food concentrated and abundant, and aggregation of over 100 individuals reported at insect emergences. While foraging for insects, jumps and hops among branches and leaves, gleaning. Individual on Mindanao hopped among outer branches, reaching under, stretching up or sallying out to pluck berries; at one point it perched perpendicularly on a branch next to a cluster of berries, and picked off and ate six berries in 33 seconds; after feeding, it flew to exposed dead branch. Captures emerging termites (Isoptera) or similar flying insects by aerial flycatching.

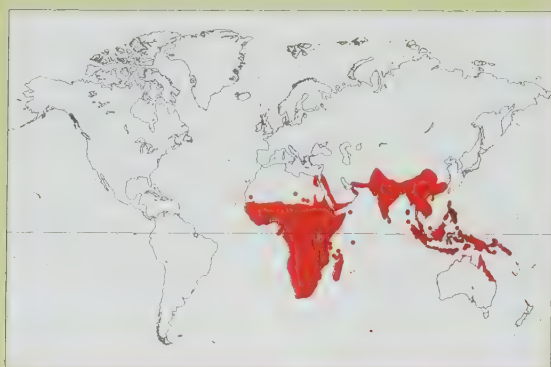

Breeding. Nest construction observed in early Apr on Biliran; birds with enlarged gonads in Apr and May and immatures in Feb and Apr–Jun. Nest in tree cavity; Biliran nest was being built c. 15 m above ground in hole of partially dead tree, provisionally identified as a binoloan (*Acmena acuminatissima*), two adults brought in small sticks 5–8 cm long, leaves c. 7 cm long and a piece of shredded bark, and time spent by birds inside nest-hole varied from 10 seconds to 6 minutes. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Relatively uncommon and local. Status on Panay not evaluated; only one sight record, of two individuals. Widespread habitat destruction is taking place throughout this species' range. On Negros, now confined to the few remaining forests: on Mt Kanla-on, around L Balinsasayao and on Cuernos de Negros.

Bibliography. Brooks & Dutton (1997), Delacour & Mayr (1946), Dickinson *et al.* (1991), Kennedy *et al.* (2000), Mayr (1957), McGregor (1909), Meyer de Schauensee & duPont (1962), Ogilvie-Grant (1896b, 1897a, 1897b), Orenstein & Kennedy (1985), Parkes (1973), duPont (1971b), Rand (1948, 1950a, 1970), Rand & Rabor (1957, 1960), Ripley & Rabor (1956, 1961, 1968), Salomonsen (1952, 1973), Whitehead (1899), Worcester & Bourns (1898), Zuccon *et al.* (2006).

Class AVES
Order PASSERIFORMES
Suborder OSCINES
Family NECTARINIIDAE (SUNBIRDS)

- Small, slender passerines with long, usually decurved bill, some with long tail; many brightly coloured, most with some iridescence, particularly in male.
- 8–23 cm.

- Old World.
- All vegetated habitats.
- 16 genera, 132 species, 396 taxa.
- 7 species threatened; none extinct since 1600.

Systematics

The sunbirds and spiderhunters comprise a well-characterized and fairly uniform family of 132 species, distributed over Africa and much of the southern part of Asia eastwards to the Australo-Papuan region. Species richness of the African nectariniids is highest in montane areas and upland savannas, centres of radiation in the recent past, although what are phylogenetically the oldest species in Africa are probably those inhabiting the Guineo-Congolese rainforest. For the family as a whole, R. C. K. Bowie's studies of nuclear and mitochondrial DNA have pointed to an Asian origin of the sunbirds, which is supported by recent analyses of vocalizations.

The syrinx is tracheobronchial, which is typical of oscine passerines, and is acromyoidian, meaning that the muscles are attached to the extremities.

Over the years, relationships between Nectariniidae and other avian groups, and the generic boundaries within the family, have been subject to varied and changing opinion. C. J. Sundevall, in his 1872 classification, placed the sunbirds in a "cohort Cinnyri-morphae", referred to also as the "Tubilingues", in which he also included four other families, consisting of some of the Neotropical honeycreepers (Thraupidae), the Hawaiian honeycreepers (Drepanididae), the Australian pardalotes (Pardalotidae) and the two sugarbirds (Promeropidae) of southern Africa, on the basis of tongue structure and a diet in which nectar figures prominently. He grouped the flowerpeckers (Dicaeidae) with the *Zosterops* white-eyes, some other Neotropical honeycreepers, the New World warblers (Parulidae) and the Australian pardalotes (*Pardalotus*) in another cohort, "Cichlomorphae", on the basis chiefly of their having nine, rather than ten, long primaries. Some ten years after Sundevall's publication, H. Gadow included the Malagasy false-sunbirds (*Neodrepanis*) in his family Nectariniidae.

Sixty years later, J. Delacour, considered the sunbirds to be close to the Dicaeidae, a view supported by E. Mayr and D. Amadon. Further, Amadon removed *Neodrepanis* from the Nectariniidae, placing it in the asity family Philepittidae, and he recognized *Hypogramma* as a separate genus. W. J. Beecher grouped the sunbirds with the flowerpeckers and white-eyes in the "sylvioid nectar feeders", which he considered to be derived from the bulbuls (Pycnonotidae), all of which he treated within an expanded family Sylviidae. In J. L. Peters's *Check-list of Birds of the World*, A. L. Rand presented the Nectariniidae as five genera, namely *Anthreptes*, *Hypogramma*, *Nectarinia*, *Aethopyga* and

Arachnothera. About a decade thereafter, W. S. Peckover and L. W. C. Filewood included in the Nectariniidae the two *Toxorhamphus* longbills, a genus traditionally classified as meliphagid but more recently found to be linked with the berrypeckers in the family Melanocharitidae. H. E. Wolters introduced a further three genera: *Deleornis*, for one of the *Anthreptes* species; *Paradeleornis*, for another of the *Anthreptes* and for one of the *Nectarinia* sunbirds; and *Haplocinnyris*, in which he placed one other of the *Nectarinia* species.

Towards the later part of the twentieth century, C. G. Sibley and J. E. Ahlquist, on the basis chiefly of evidence obtained from their studies involving DNA-DNA hybridization, presented a slightly different arrangement. Their classification included an enlarged Nectariniidae, which they split into two subfamilies. These were the Promeropinae, containing the two *Promerops* sugarbirds, and the Nectariniinae; the latter was further divided into two tribes, namely the Nectariniini, including the same genera as in Rand's Nectariniidae, and the Dicaeini, which housed the two flowerpecker genera *Prionochilus* and *Dicaeum*. M. P. S. Irwin then expanded the number of sunbird genera by splitting *Anthreptes* and *Nectarinia*; he added *Deleornis* and *Hedydipna*, formerly merged with *Anthreptes*, and *Anabathmis*, *Dreptes*, *Anthobaphes*, *Cyanomitra*, *Chalcomitra*, *Leptocoma* and *Cinnyris*, all of which had previously been subsumed in *Nectarinia*.

R. A. Cheke and C. F. Mann, in their 2001 monograph, added the genus *Chalcoparia*, which had previously been merged with *Anthreptes*, and *Drepanorhynchus*, hitherto treated within *Nectarinia*. Both of these resurrected genera are monotypic. It seems sensible, for the sake of convenience, to follow this latest arrangement for the time being, although it is worth noting that the genus *Hedydipna* has been replaced by *Anthodiaeta*, which has been shown to have precedence over the former name. Furthermore, it is very likely that future research will lead to additional changes in the coming years.

In the sequence presently followed, the first genus in the family is *Chalcoparia*. This contains a single species, the Ruby-checked Sunbird (*Chalcoparia singalensis*), found in South-east Asia and the Greater Sundas. This species has the bill shorter than the head, with a very slightly curved culmen, a straight lower mandible and, in contrast to other sunbirds, no serrations. The non-tubular tongue is similarly unique among the nectariniids, coming closer to that of some flowerpeckers, particularly the *Prionochilus* flowerpeckers. In terms of its habits, the Ruby-checked Sunbird

is reminiscent more of the white-eyes and of small babblers (Timaliidae). The argument that it is somewhat distant from other sunbirds is supported by Bowie and colleagues' study of nuclear and mitochondrial DNA of this avian group. This genus may merit separation in a monotypic family or subfamily.

The two species in *Deleornis*, the Scarlet-tufted (*Deleornis fraseri*) and Grey-headed Sunbirds (*Deleornis axillaris*), are of West and Central African distribution. In the past they were considered conspecific, but they are probably better treated as two members of a superspecies. The bill is short, stouter than that of *Anthreptes* and almost straight, with a completely straight lower mandible. The tapered tongue is slightly convex in cross-section, and the distal quarter forms two incomplete, much-fimbriated tubes. The tail is nearly square, with the outermost rectrices much shorter than the rest. *Deleornis* exhibits no iridescence in the plumage, and the only outward difference between the sexes is that the males possess brightly coloured pectoral tufts. These sunbirds are rather similar to the Old World warblers (Sylviidae) in appearance and behaviour.

Fourteen species, occurring in Africa, South-east Asia, the Greater Sundas, the Philippines and western Wallacea, make up the genus *Anthreptes*. Their habits are, again, reminiscent of those of Old World warblers. All are small, and have a rather short, slightly curved bill with the basal third straight. The tongue is long and narrow, forming a tube for four-fifths of its length, with the distal fifth bifurcate and creating two incomplete tubes, each with three points on the inner edge. The square-ended tail is of short or medium length, and never elongated. Some members of the genus display marked sexual dichromatism, and most, at least in the male, have some iridescence. Analyses of mitochondrial DNA have suggested the possibility that the genus as currently constituted is not monophyletic, as the African members represent a separate lineage and should, therefore, be placed in a separate genus. This is supported by the results of preliminary studies of the alimentary canal. The Plain-backed (*Anthreptes reichenowi*), Anchieta's (*Anthreptes anchietae*), Plain (*Anthreptes simplex*), Mouse-brown (*Anthreptes gabonicus*) and Little Green Sunbirds (*Anthreptes seimundi*) appear to be isolated, none hav-

ing any close relative. In contrast, the Brown-throated (*Anthreptes malacensis*) and Grey-throated Sunbirds (*Anthreptes griseigularis*) were for many years treated as conspecific, but they are now considered to be separate species forming a superspecies. They are distinct not only in plumage, but also in details of measurements, and they show no evidence of hybridization or introgression. Although the range of the Red-throated Sunbird (*Anthreptes rhodolaemus*) is contained entirely within that of the Brown-throated Sunbird, these Oriental species appear to be close relatives of each other and the Red-throated may be part of the same superspecies. J. C. Brown concluded that the Grey-throated Sunbird once inhabited much of the present area of distribution of the Brown-throated Sunbird in Indonesia and the Philippines, but that, during the last glaciation, it was replaced in the former region, and in much of the latter archipelago, by *malacensis*. The Grey-throated Sunbird is now found only in eastern parts of the Philippines, and the only island inhabited by both of these species is Mindanao, where the Grey-throated Sunbird is present only to the east of the Diuata range, whereas its relative is found only to the west of this range. There may have been two invasions of the Philippines by the Brown-throated Sunbird, first by representatives of the "chlogaster group" and latterly by the "nominate group".

The Western Violet-backed (*Anthreptes longuemarei*), Kenya Violet-backed (*Anthreptes orientalis*), Uluguru Violet-backed (*Anthreptes neglectus*) and Violet-tailed Sunbirds (*Anthreptes aurantius*) form a superspecies, their ranges exhibiting barely any geographical overlap. The first three are particularly closely related, as was indicated by the results of the molecular-genetic study undertaken by Bowie and co-workers. The Straight-billed Green Sunbird (*Anthreptes rectirostris*) and the geographically isolated Banded Sunbird (*Anthreptes rubritorques*), once considered to be conspecific, constitute a further superspecies.

Four species confined to Africa and Arabia are united in the genus *Anthodiaeta*. These are small sunbirds having a short, broad-based bill with only a slight curvature, which begins at the base. The proximal three-quarters of the long tongue are narrow and flat, with the edges rolled inwards to form two tubes, and the

The sunbirds are generally small, fairly slim birds, and males of many species, such as the **Ruby-cheeked Sunbird**, are brightly coloured. The English name of this species refers to the male's copper ear-coverts, which are framed by an iridescent blue-green crown and chestnut throat and upper breast. The Ruby-cheeked Sunbird occupies a monotypic genus and is unusual amongst the Nectariniidae in its bill and tongue structure. In all family members, the bill is narrow and pointed, but only the Ruby-cheeked lacks fine serrations near the tip. Unlike most sunbirds, its bill is shorter than its head, its lower mandible is straight rather than decurved, and the tongue is flattened rather than tubular. It has been suggested that it may merit treatment in a separate monospecific family.

Not surprisingly, in a sizeable family of 132 species shared among 16 genera, there is a considerable array of plumage patterns and coloration types. As well as differences between genera, there is also considerable variation within individual genera. At first glance, one could be forgiven for thinking that the birds in this pair of photographs were not closely related, but they are: both the **Brown-throated Sunbird** and the **Plain Sunbird** belong to the genus *Anthreptes*. Both these individuals are males, vividly representing opposite extremes in terms of plumage coloration. The Brown-throated shows strong sexual dichromatism, males being significantly brighter than females in all 16 races. These differ mainly in the male's plumage tone and the colour of the iridescence. The races fall into two plumage groups. This individual, a bird of the nominate race, is in the group of males that have iridescent violet upperparts and vivid yellow underparts, as opposed to the iridescent dark green upperparts and olive-green underparts of the other group. In contrast to this spectacular species, the aptly named Plain Sunbird is dull olive-green above and greyish-olive below in both sexes. There is, however, partial sexual dichromatism, as the female lacks the male's metallic blue or green forehead.

[Above: *Anthreptes malacensis malacensis*, Chinese Garden, Singapore. Photo: Jimmy Chew.

Below: *Anthreptes simplex*, Panti Forest, Peninsular Malaysia. Photo: Ong Kiem Sian]

distal quarter is bifurcated and forms two complete tubes, with the inner edges fimbriated. They are sexually dimorphic, and the males of two of the species, the Pygmy Sunbird (*Anthodiaeta platura*) and the Nile Valley Sunbird (*Anthodiaeta metallica*), have the central rectrices greatly elongated. Plumage iridescence is present only in the males of these two, but in both sexes of the two short-tailed species. Once considered to be conspecific, the Pygmy and Nile Valley Sunbirds constitute a well-defined superspecies, and a third species, the Collared Sunbird (*Anthodiaeta collaris*), is probably close to these two. The fourth member of this genus, the Amani Sunbird (*Anthodiaeta pallidigaster*), is somewhat different from the others, and it has been suggested that it may be close to the Oriental genus *Leptocoma*, although it has a much shorter bill than the latter and exhibits few similarities in plumage.

Hypogramma contains a single, medium-sized species, the Purple-naped Sunbird (*Hypogramma hypogrammicum*), found in South-east Asia, Sumatra and Borneo. It has a longish bill with a curved culmen and straight lower mandible. The tongue, unlike that of any other sunbird, is rolled at the edges to form two half-tubes for much of its length; the distal fifth is split centrally, the inner edges deeply fimbriated, and each half is split again for half of its length, thereby forming a four-pronged brush-like tip. The tail is rounded. The male differs from the female in having a metallic purplish nuchal patch and tufts of elongated metallic feathers at the base of the lower back, characters found in no other sunbird. The Purple-naped Sunbird is somewhat babbler-like in its behaviour. It possibly merits separation in its own subfamily.

The genus *Anabathmis* houses three small to medium-sized West African nectariniids. All have a strong bill, decurved from the base, and a graduated tail. The Principe (*Anabathmis hartlaubii*) and Newton's Sunbirds (*Anabathmis newtonii*) may form a superspecies, although the former is much the larger of the two, but the third member of the genus, Reichenbach's Sunbird (*Anabathmis reichenbachii*), is rather different in appearance. The first two species are superficially more similar to *Dreptes* than they are to Reichenbach's Sunbird. Bowie's work on the molecular genetics of sunbirds places *hartlaubii* and *reichenbachii* at some distance from each other, and each closer to some members of *Cinnyris* than those members are to other sunbirds currently placed in *Cinnyris*. However, Iddi's analyses of vocalizations place *hartlaubi*, *newtonii* and the Sao Tome Sunbird (*Dreptes thomensis*) closer to *reichenbachii* than to any other species, suggesting that *reichenbachii* invaded from the continent and radiated on the islands.

Placed in the monotypic *Dreptes*, the Sao Tome Sunbird is, like Newton's Sunbird, confined to the island of São Tomé, in the Gulf of Guinea, West Africa. The largest of all sunbirds, it has a long decurved bill, a long graduated tail, and only slight iridescence in the plumage. The sexes are similar. The genus is probably close to *Anabathmis*, showing certain resemblances to two of the three species. This view is supported by analyses of vocalizations, the results of which are as yet unpublished.

Another monotypic genus contains a South African species, the Orange-breasted Sunbird (*Anthobaphes violacea*). This has a medium-long, thin and curved bill. The edges of the long, narrow tongue are curled inwards to form two tubes; the distal quarter is bifurcate, forming two non-fimbriated tubes with helical walls. The tail is graduated, and that of the male has the central rectrices noticeably elongated. A recent DNA study suggests that the Orange-breasted Sunbird is closer to some *Cinnyris* species than some members of the latter genus are to each other.

The genus *Cyanomitra* contains eight species confined to Africa. These are medium-sized, with a long, heavy bill that is slightly but distinctly curved. The long, narrow tongue has rolled edges, forming a single complete tube, over three-quarters of its length; the distal quarter broadens, and is split to create two almost complete tubes, the inner edges of which are jagged. The males are larger than the females, and sexual dichromatism is apparent in five species. The Green-headed (*Cyanomitra verticalis*), Bannerman's (*Cyanomitra bannermani*), the Cameroon (*Cyanomitra oritis*) and the Blue-headed Sunbirds (*Cyanomitra alinae*) possibly form a group, and could perhaps be considered as a superspecies, the first two being particularly

There is substantial variation in tail length among nectariniids, and this characteristic also plays its part in sexual dimorphism. Males of 21 species of sunbird in six genera have elongated central tail feathers, a feature absent in their females. These protruding rectrices form roughly half the overall length of the **Pygmy Sunbird**. This species is one of four species that make up the genus *Anthodiaeta*, which occurs in Africa and Arabia. These small sunbirds have a short, slightly decurved bill with a broad base.

[*Anthodiaeta platura*, Lake Chad, Bornu, NE Nigeria.

closely related to each other. The relationship of *alinae*, *oritis* and *verticalis* is supported by Bowie's DNA results, which indicate that the Blue-throated Brown Sunbird (*Cyanomitra cyanolaema*) is a sister-taxon to this group. The Eastern Olive Sunbird (*Cyanomitra olivacea*) and the Western Olive Sunbird (*Cyanomitra obscura*) lack iridescence, and were for long considered to be conspecific. P. A. Clancey separated them, a taxonomic decision accepted both by Irwin, in volume VI of *The Birds of Africa*, and by Cheke and Mann, in their 2001 monograph, although Irwin, after reconsideration, expressed the view that the two should be recombined as a single species. Intriguingly, a molecular-genetic study, using mitochondrial DNA, appears to

The only member of its genus, the **Purple-naped Sunbird** differs sufficiently from other sunbirds in its tongue morphology and babbler-like behaviour to prompt suggestions that it merits its own subfamily. This large, stocky sunbird has a fairly long bill, the upper mandible of which is decurved and the lower straight. Both sexes are olive-green above, and broadly olive-yellow below. The male differs from the female in having an iridescent nuchal half-collar, lower back, rump and uppertail-coverts, the colour of which varies from blue to purple in the five races. The elongated feathers of the lower back are not found in any other sunbird.

[*Hypogramma hypogrammicum*, *hypogrammicum*, Tabin Reserve, Sabah, Borneo.

demonstrate that neither the Eastern Olive Sunbird nor the Western Olive Sunbird, as presently understood, is monophyletic. The Mouse-coloured Sunbird (*Cyanomitra veroxii*) and the Blue-throated Brown Sunbird are rather different from their congeners, and also from each other. The latter's female plumage resembles that of other *Cyanomitra* species, whereas the male's plumage is suggestive of *Chalcomitra*.

Seven African species are placed in the genus *Chalcomitra*, which seems to be close to *Cyanomitra*. These are medium-sized

to large, rather stocky sunbirds with a heavy, markedly decurved bill. The tongue structure is similar to that of *Cyanomitra*, but the tongue broadens at the tip and is less deeply bifurcated. The tail is square-ended. The males are generally larger than the females, and most of the seven species are also sexually dichromatic, some markedly so but others only slightly. Two have pectoral tufts, and the rest do not. The plumage is primarily brown, males having some iridescent brighter feathering on the head, at least. There is an exception to this general rule, the geographically isolated Socotra Sunbird (*Chalcomitra balfouri*) differing from all others in the genus in that it lacks iridescence, the male having female-like plumage. The Socotra Sunbird appears to have no close relative. The Carmelite (*Chalcomitra fuliginosa*), Amethyst (*Chalcomitra amethystina*) and Green-throated Sunbirds (*Chalcomitra rubescens*) constitute a well-marked group, perhaps forming a superspecies, although the Green-throated Sunbird has been linked to the Buff-throated Sunbird (*Chalcomitra adelberti*). The Scarlet-chested (*Chalcomitra senegalensis*) and Hunter's Sunbirds (*Chalcomitra hunteri*) have mostly discrete ranges and form a superspecies. The studies of nuclear and mitochondrial DNA by Bowie and others found that *amethystina*, *rubescens* and *adelberti* were linked, with *senegalensis* also close. Mitochondrial DNA studies undertaken by B. H. Warren and colleagues, however, associated the Buff-throated and Scarlet-chested Sunbirds with three species in other genera, namely the Long-billed Green (*Cinnyris notatus*) and Red-chested Sunbirds (*Cinnyris erythrocercus*) and the Bronze Sunbird (*Nectarinia kilimensis*).

In tropical Asia, five small species of sunbird, all possessing a curved, rather weak bill, make up the genus *Leptocoma*. The genus is characterized by having the nasal operculum feathered. The tongue has rolled edges forming a single tube proximally, this becoming a double tube with a common inner wall, and finally two separate tubes over the distal tenth of its length. The tail varies from being short and square to being rounded or graduated, and to being fairly long. There is much velvety feathering, but iridescence in the plumage is restricted. The Crimson-backed (*Leptocoma minima*) and Purple-throated Sunbirds (*Leptocoma sperata*) could be considered to form a superspecies, and the Black (*Leptocoma sericea*) and Copper-throated Sunbirds (*Leptocoma calcostetha*) could be regarded as forming another; it has been suggested also that, instead, the Purple-throated and Black

The three members of the West African genus *Anabathmis* are small to medium-sized sunbirds. All three share two key morphological features: a thickset, decurved bill; and a graduated tail.

Reichenbach's Sunbird differs from its congeners, however, in possessing pectoral tufts and being only very slightly sexually dichromatic. Both sexes have a dark metallic blue head and throat, with a violet and green sheen; a pale grey breast and upper belly; and yellow pectoral tufts, lower belly and undertail-coverts. The female only differs from the male in being slightly smaller and having duller pectoral tufts. Such male-type plumage is very unusual for sunbirds that lack sexual pronounced dichromatism.

[*Anabathmis reichenbachii*, Limbe Botanical Gardens, Cameroon.
Photo: Ketil Knudsen]

Current taxonomy treats *Anthobaphes* as a monotypic genus, comprising the **Orange-breasted Sunbird**. Recent DNA analysis, however, has introduced a modicum of doubt, the species emerging as genetically closer to some *Cinnyris* sunbirds than some members of this genus are to each other. Whatever its taxonomic relationships, the male Orange-breasted Sunbird is a striking bird, with its elongated central tail feathers and metallic green head, throat, upper breast and mantle. A subtle violet breastband separates the throat from otherwise orangish underparts. The female shows none of the male's finery.

[*Anthobaphes violacea*, South Africa.
Photo: Michael Gore]

The African genus *Cyanomitra* comprises eight medium-sized species with fairly long, hefty, decurved bills. The **Mouse-coloured Sunbird** is, as its name suggests, one of the duller species. The sexes are alike, being grey-brown above, with a metallic blue-green sheen in two races, and dull greyish-olive below. All *Cyanomitra* have pectoral tufts, but the **Mouse-coloured Sunbird** differs from all but one of its congeners in that both sexes have them, rather than just the male. The pectoral tufts are used to good effect in display, when birds will expose the tufts while fluttering the wings and raising the tail.

[*Cyanomitra veroxii*
veroxii,
Nkwale Valley,

South Africa.
Photo: Guy Upfold]

The genus *Chalcomitra* consists of seven African species. All are medium-sized and rather heavily-built, with a long, strong, markedly decurved bill. Members of this genus are predominantly dark brown, with iridescence generally restricted to the male's head, but the male **Hunter's Sunbird** is very attractively attired. It has a vivid scarlet lower throat and breast, a green moustachial stripe and purple gloss to the lesser wing-coverts and uppertail-coverts that feature prominently on an otherwise black plumage. As with all congeners bar one, **Hunter's Sunbird** shows strong sexual dichromatism.

Birds As Art]

Sunbirds form a superspecies. The Purple-rumped Sunbird (*Leptocoma zeylonica*) is probably close to the first pair. Below the species level, the rather uniform "brasilianna group" of subspecies of the Purple-throated Sunbird may perhaps warrant separation as a species, distinct from the rather varied "nominate group". As mentioned within the preceding paragraphs, it has been suggested that the Amani Sunbird, an Afrotropical species currently placed in *Anthodiaeta*, may, in fact, be closer to this Asiatic genus, but the Amani Sunbird not only has a different plumage from that of *Leptocoma* but also a much shorter bill than that of the latter genus.

The genus *Nectarinia* comprises six medium-sized, sleek African sunbirds with a rather straight or curved bill of medium to long length. The tongue is very long and narrow, with the edges rolled inwards to form a tube; the distal tenth is bifurcated, opening out to form two tubes of helical structure with somewhat jagged edges. Males in this genus exhibit much iridescence in the plumage, and have the tail square-ended or graduated, with the central rectrices elongated and protruding 45–130 mm beyond the next longest pair. Males of two of the species have pectoral tufts. The females have dull-coloured plumage, chiefly olive above and pale yellowish to greyish below, with an iridescent dark tail. Bocage's (*Nectarinia bocagii*), Purple-breasted (*Nectarinia purpureiventris*) and Tacazze Sunbirds (*Nectarinia tacazze*) possibly constitute a superspecies, and the Red-tufted (*Nectarinia johnstoni*) and Malachite Sunbirds (*Nectarinia famosa*) another. The Bronze Sunbird seems to be more isolated. Bowie's DNA-based research indicates a link between *famosa* and *johnstoni*, and suggests also a grouping of the Purple-breasted, Tacazze and Bronze Sunbirds, but, interestingly, it places the Golden-winged Sunbird (*Drepanorhynchus reichenowi*) within this latter group.

The Golden-winged Sunbird, an African highland species, is the sole member of the genus *Drepanorhynchus*. It is a rather large sunbird, with a markedly decurved bill. The male has a long tail, the central feathers of which are greatly elongated. Uniquely among sunbirds, both sexes have large golden patches on the wings and tail. Both also have a V-shaped unfeathered area extending from the bill base through the forehead to the forecrown; this groove accumulates pollen as the bird probes in flowers, and it increases in size with wear, becoming up to 9.5 mm long and up to 3.2 mm across at its widest point, near the bill.

Fifty species are contained in *Cinnyris*, making this by far the biggest genus in the family. Its range covers Africa, Madagascar, the Indian Ocean islands, the Middle East, tropical Asia, the New Guinea region and Australia. These are for the most part medium-sized sunbirds with a fine, slightly or strongly decurved, short or medium-length bill. The tongue is long and narrow, the sides curving inwards to form two tubes; the distal 15% or so is split to form two separate tubes, with no obvious fimbriations except at the very tip. The males have iridescent

plumage, especially on the upperside, and they usually possess pectoral tufts, whereas the females are plain and lack pectoral tufts. The males of four of the 50 species have markedly elongated central rectrices. The genus can be divided into six groups, as follows: 16 species of double-collared sunbird; twelve purple-banded species; four maroon species, based on the colour of the underparts of the Superb Sunbird (*Cinnyris superbus*) and its two close relatives, and with the somewhat arbitrary inclusion of the Rufous-winged Sunbird (*Cinnyris rufipennis*); four species of white-bellied sunbird; two olive species, namely Ursula's (*Cinnyris ursulae*) and Bates's Sunbirds (*Cinnyris batesi*); and twelve species in a miscellaneous group comprising the Copper Sunbird (*Cinnyris cupreus*) and species which do not occur on the African mainland.

The first of these groups contains three possible superspecies. The Miombo Double-collared (*Cinnyris manoensis*) and Southern Double-collared Sunbirds (*Cinnyris chalybeus*) form one of these, Stuhlmann's Double-collared (*Cinnyris stuhlmanni*), Prigogine's Double-collared (*Cinnyris prigoginei*), the Montane Double-collared (*Cinnyris ludovicensis*) and the Greater Double-collared Sunbirds (*Cinnyris afer*) perhaps form a second superspecies, and the Eastern Double-collared (*Cinnyris mediocris*), Moreau's (*Cinnyris moreaui*) and Loveridge's Sunbirds (*Cinnyris loveridgei*) constitute a third. Close relationships among this last trio are supported by Bowie's findings from nuclear and mitochondrial DNA analyses, which also link the Southern Double-collared and Northern Double-collared Sunbirds (*Cinnyris reichenowi*) to these three and, more distantly, to the Greater Double-collared and Regal Sunbirds (*Cinnyris regius*). Further studies of mitochondrial DNA, carried out by Bowie and colleagues, indicate that Moreau's Sunbird, rather than being a hybrid between Eastern Double-collared and Loveridge's Sunbirds as had been suggested, is indeed a valid taxon. They indicate also that the Eastern Double-collared Sunbird should be divided into three species, with the nominate race, *usambarica* and *fuelleborni* each accorded species status, although the position of the southernmost race, *bensoni*, is unclear. In this analysis, *moreaui*, *loveridgei* and *fuelleborni* were found to form a sister-clade to *mediocris* and *usambarica*. In 2005, Irwin treated the two subspecies of Shelley's Sunbird (*Cinnyris shelleyi*) as separate species, a decision taken on morphological grounds and

on the basis that their distributions possibly overlap in southern Tanzania. In addition, it has recently been suggested that the subspecies *pintoii* of the Miombo Double-collared Sunbird should be considered a separate species, as it and the nominate race overlap geographically but not ecologically in Zambia. Also, an undescribed taxon apparently closely related to the Greater Double-collared Sunbird, but probably closer to the Montane Double-collared of the subspecies *whytei* or to the Miombo Double-collared Sunbird, has recently been discovered in the Eastern Arc mountains of Tanzania and in north-east Zambia. In Tanzania, it seems to be fairly common at some localities in the Udzungwas and the Rubeho Mountains, occurring at forest edges and towards the rainshadow north-west of the mountains. Populations of this taxon in Zambia have been found nesting at Mutinondo and Kipiri Mposhi, building nests of grass and laying eggs that were pale and freckled. This contrasts with the Miombo Double-collared Sunbird, which, in Zambia, makes its nests from *Usnea* lichen and lays dark plain olive or chocolate-coloured eggs.

Finally, DNA analysis suggests a relationship between the Olive-bellied Sunbird (*Cinnyris chloropygius*) and the Tiny Sunbird (*Cinnyris minullus*), but also links them with two species from the "maroon group", namely the Superb and Rufous-winged Sunbirds.

The second group, the purple-banded species, contains four superspecies: the first consists of the Mariqua (*Cinnyris mariquensis*) and Shelley's Sunbirds; the second, the Congo (*Cinnyris congensis*) and Red-chested Sunbirds; the third, the Common Purple-banded (*Cinnyris bifasciatus*) and Tsavo Purple-banded Sunbirds (*Cinnyris tsavoensis*); and the fourth, the Violet-breasted (*Cinnyris chalcopelas*) and Pemba Sunbirds (*Cinnyris pembae*). A close relationship of *erythrocercus*, the Red-chested Sunbird, with *bifasciatus* and *mariquensis* is supported by Bowie's study of nuclear and mitochondrial DNA. This study further indicates a relationship between the Palestine (*Cinnyris osea*) and Orange-tufted Sunbirds (*Cinnyris bouvieri*). The "white-bellied group" contains one superspecies, comprising Oustalet's (*Cinnyris oustaleti*) and the White-breasted Sunbirds (*Cinnyris talatala*); interestingly, other DNA work suggests a relationship between these two and, from the "purple-banded group", the Palestine and Orange-tufted Sunbirds.

The five species of *Leptocoma* occur over a broad band stretching from India east to New Guinea. All have a relatively long, slight, decurved bill, but tail length and shape varies considerably among species. The males are very striking, their mainly black plumage providing the backdrop to patches of vivid colour and metallic sheen. All five species are sexually dichromatic, with the female considerably drabber. The male **Black Sunbird** is predominantly velvet-black, with a metallic gloss to the crown, upperwing-coverts, mantle, uppertail-coverts and throat, the colours of which vary according to race.

The **Golden-winged Sunbird** is the sole member of the genus *Drepanorhynchus*. It inhabits uplands in East Africa and eastern parts of West Africa. This large, striking nectariniid has a sharply decurved bill and substantial golden areas on the wing and tail. The tail in both sexes is long and graduated, particularly in the male, where the central rectrices extend 70 mm beyond the others and can form a third of the bird's overall length. Both sexes have a V-shaped, unfeathered groove between the bill and the forehead, which can measure nearly 1 cm. As the bird reaches inside flowers, pollen accumulates in this unusual feature.

[*Drepanorhynchus*
reichenowi *reichenowi*,

The genus *Nectarinia* has often been extended to include a large proportion of sunbird species, but nowadays it is normally defined much more narrowly.

As such, it comprises six African species, all medium-sized and slim. Bill shape varies among the species, being straight in some and decurved in others. Male tail shape also differs: it is square-ended in some species, but graduated in others, such as the **Tacazze Sunbird**. Males of all species have elongated central rectrices, those of the Tacazze Sunbird extending rather less than those of most of its congeners. All *Nectarinia* are sexually dichromatic, although the males of some, including the Tacazze Sunbird, assume a less gaudy plumage outside the breeding season.

In the "miscellaneous group" there are two apparent super-species. The first contains the Olive-backed (*Cinnyris jugularis*) and Apricot-breasted Sunbirds (*Cinnyris buettikoferi*), and could possibly include also the Flame-breasted Sunbird (*Cinnyris solaris*), although this and the Olive-backed Sunbird overlap considerably in range. These species are Asian in distribution, the first extending to Australia. The second superspecies contains the Souimanga (*Cinnyris sovimanga*), Humblot's (*Cinnyris*

humbloti) and Anjouan Sunbirds (*Cinnyris comorensis*) from the Malagasy Region. A close relationship among these three is suggested by Bowie's studies, and subsequent mitochondrial DNA studies by Warren and co-workers place the Seychelles Sunbird (*Cinnyris dussumieri*) in this clade, with the Orange-tufted, Variable (*Cinnyris venustus*) and the white-bellied species as a sister-group. Bowie's molecular-genetic investigations also indicate a close relationship between the Copper Sunbird and the Beautiful Sunbird (*Cinnyris pulchellus*), the latter belonging to the "double-banded group". Warren and colleagues found that the Long-billed Green Sunbird of the Malagasy Region was apparently closely related not only to the Red-chested Sunbird, but also to the Scarlet-chested and Buff-throated Sunbirds, both in the genus *Chalcomitra*, and the Bronze Sunbird, in *Nectarinia*. Further, and supported by geological evidence, the latter studies indicate two invasions of the Indian Ocean islands by sunbirds since about 3·9 million years ago. One, involving the "notatus clade", colonized first the Comoro Archipelago, and then Madagascar. The second, the "sovimanga clade", invaded the Comoros, and subsequently evolved several lineages, including four extant ones. The first of these four reached the Seychelles (*C. dussumieri*), the second (*C. coquerellii*) is found on Mayotte, and the third (*C. humbloti*) on Grand Comoro and Mohéli; finally, the fourth lineage evolved on the Comoro island of Anjouan (*C. comorensis*), and then invaded Madagascar (nominate race of *C. sovimanga*) and finally the Aldabra atoll (races *abbotti*, *aldabrensis* and *buchenorum* of *C. sovimanga*).

With 18 species in total, *Aethopyga* is the second largest genus in the family. It is restricted to tropical Asia, where eight of the species occur in the Philippines. Seven of these are, indeed, confined to that archipelago, which is where the genus exhibits its greatest radiation, and which is perhaps its area of origin. The bill of *Aethopyga* is slightly longer than the head, and is decurved, with a ridged culmen; the nostrils are bare, longitudinal and operculate. The long tongue is rolled inwards at the sides to form a tube, which towards the tip has two lateral splits forming two groove-like structures, and with a ventral plate which may be used to convert the two lateral grooves into two separate tubes. The tail is graduated, and the males of many species have the central rectrices projecting far beyond the others. The sexes differ in plumage. The male almost invariably has a contrasting yel-

Some 50 species, more than one-third of all sunbirds, are currently placed in the genus *Cinnyris*, making it far the largest genus in the family. It is also the most widespread, with a cumulative range extending from the Middle East, to Africa and from tropical Asia to Australia. Most of its members are medium-sized, and have a fine, decurved, short to medium-length bill. The genus can be split into six groups. The **Mariqua Sunbird** is one of twelve purple-banded species, so termed because of their violet-blue breastband. Within this group, as with many *Cinnyris*, males have bright iridescent plumage while the females are much duller.

low patch of variable size on the lower back and rump, and the female frequently has this feature. Four superspecies are recognized. The Apo (*Aethopyga boltoni*) and Lina's Sunbirds (*Aethopyga linaraborae*) form one, and this may possibly include also the Flaming Sunbird (*Aethopyga flagrans*). The Lovely (*Aethopyga shelleyi*) and Handsome Sunbirds (*Aethopyga bella*), previously considered conspecific, constitute another superspecies, and Vigors's Sunbird (*Aethopyga vigorsii*) and the Crimson Sunbird (*Aethopyga siparaja*), likewise previously considered conspecific, form a third. The fourth superspecies in this genus consists of the Javan (*Aethopyga mystacalis*) and Temminck's Sunbirds (*Aethopyga temminckii*), which were previously united under the name "Scarlet Sunbird".

Last in the current sequence of nectariniid genera is *Arachnothera*, containing the ten species of spiderhunter. All of these are inhabitants of tropical Asia. They are robust, and larger than almost all of the sunbirds. The sexes are similar and, unlike the majority of sunbirds, both sexes incubate. Most of the spiderhunters have greenish plumage, and all of them lack iridescence. The bill is long or very long, at least twice the length of the head, stout, strongly decurved, and with a ridge between the nostrils. The long tongue is rolled to form a complete tube for most of its length, but it has two lateral splits on its distal tenth, and these also are inwardly rolled to form two tubes, which are completed by the ventral section, as is the case with the *Aethopyga* sunbirds. The Grey-breasted (*Arachnothera modesta*) and Streaky-breasted Spiderhunters (*Arachnothera affinis*) are sometimes considered to form a superspecies. Although the nominate

race of the former and the subspecies *everetti* of the latter overlap in range in Borneo, *everetti* is generally found at higher altitudes than those frequented by the Grey-breasted Spiderhunter. These two species, incidentally, have in the past sometimes been treated as conspecific or, perhaps more often, *everetti* was considered a separate, monotypic species, and all other taxa combined under *A. affinis*.

As a final point, some suspicions have been expressed that an undescribed nectariniid species occurs in Djibouti, on the north-east African coast of the Red Sea. Cheke and Mann, in their 2001 monograph, put forward the view that the individual birds reported were probably of a known species, such as a Shining Sunbird (*Cinnyris habessinicus*) or a Mariqua Sunbird, the crown of which had become dusted with yellow pollen.

It is quite apparent that there remains much to be learnt about the relationships of the species within this family. Many of the newer approaches to the classification of these birds have been based almost entirely on molecular-genetic evidence, and continuation of such investigative research will no doubt throw up further reasons for modifying the existing taxonomy. It is worth bearing in mind, however, that evidence derived from anatomical and morphological studies, studies of vocal and breeding behaviour and other phenomena could prove of equal interest and scientific value.

Morphological Aspects

The members of this family are small to very small, the sunbirds generally ranging in length from 8 cm to 16 cm, with the exception of the Sao Tome Sunbird, which reaches 23 cm, and the very long-tailed male of the Fire-tailed Sunbird (*Aethopyga ignicauda*), which attains 20 cm. Recorded masses of sunbirds are from 4 g to 21.6 g. The spiderhunters range up to 22 cm in length, and to 49 g in mass.

Characteristically, the bill is narrow, sharply pointed and, except in the case of the Ruby-cheeked Sunbird, finely serrated near the tip. It is usually decurved, and it varies in length from being slightly shorter than the head, as with the Ruby-cheeked Sunbird, to being about three times the length of the head, as illustrated by the Long-billed Spiderhunter (*Arachnothera robusta*); in the sunbirds, there is a positive correlation between bill length and body mass. The upper mandible has a curvature varying from slight to pronounced; the lower mandible of the Ruby-cheeked Sunbird and the two species of *Deleornis* is straight, but in all other members of the family it is curved, at least distally. The nostrils are generally oval in shape, more rounded in some species and elongate in others, and are in a groove, protected from pollen by opercula. Rictal bristles are absent.

With the exception of the Ruby-cheeked Sunbird, which has a flattened tongue, the nectariniid tongue is tubular, and is bifurcate distally. It has fimbriated or frayed edges, allowing nectar to be taken into the bill by capillary action. Two grooves in the palate, coupled with the tubular structure of the tongue, facilitate the action of the tongue and bill as a pump during the process of nectar-drinking. In the Ruby-cheeked Sunbird, the tongue is a narrow rectangular plate, concave in transverse section, forming two fimbriated prongs distally, and with the distal edges of the plate also fimbriated. That of *Deleornis* is a long, narrow concave plate tapering distally, with the edges rolled to form two tubes; the distal end forms two prongs, which are rolled to form two complete tubes, fimbriated along their inner edges. Species in *Anthreptes* and *Leptocoma* have a tongue that is rolled for most of its length to form one complete tube, and split at the distal end to form semi-tubes, which are fimbriated on the inner edges. The tongue of *Anthodiaeta* is similar to that of *Deleornis*, but less broad-based, with a narrower unrolled central section, and the lateral tubes are more prominent. In *Hypogramma*, the tongue is a narrow flat plate for much of its length, with the sides rolled to form tubes, and the tip four-pronged, with the inner edges of the outer prongs fimbriated. In *Cyanomitra*, *Chalcomitra*, *Drepanorhynchus* and *Nectarinia*, it is a long narrow tube for much of its length, split towards the tip to form two spiral tubes that are fimbriated on their inner edges. *Anthobaphes* has a long, narrow

While the large majority of sunbirds of the genus *Cinnyris* are brightly coloured, some are rather less so. A good example of the latter is the **Dusky Sunbird**. As its English and scientific names suggest, it is dark brown to black over much of its plumage. While there is some bronze, purple, green and blue iridescence to various parts of the body, the sheen is much less eye-catching than on most of its congeners. It is one of a group of four white-bellied species within *Cinnyris*. At the same time, it is one of 16 species in the genus for which the male has a distinct non-breeding or eclipse plumage. In this species, the iridescence all but disappears and the black feathering is much reduced. The female is dull brown above, darker on the tail and uppertail-coverts, and pale below.

[*Cinnyris fuscus fuscus*, South Africa.
Photo: Roland Seitre]

Just under one-third of the 50 members of the genus *Cinnyris* are grouped together as "double-collared sunbirds", the name referring to the narrow blue and broad red breastbands exhibited by males of the species.

As can be seen here, double-collared sunbirds appear strikingly similar.

The males of the four species shown here all have a decurved bill and follow the same plumage pattern: iridescent green head, throat, upper breast, mantle and wing-coverts; brown remiges; blue and red breastbands; and greyish belly and undertail-coverts.

The **Miombo Double-collared Sunbird** (above left) occurs in three races from Angola east to Mozambique. The **Eastern Double-collared Sunbird** (above right) is restricted to East Africa between Kenya and Mozambique.

The **Greater Double-collared Sunbird** (below left) occurs in southern Africa and may form a superspecies with the **Northern Double-collared Sunbird** (below right) of West and East Africa.

Racial variation in plumage occurs in many sunbirds. The **Variable Sunbird** is a good example of this, as, of course, its name suggests. Its five subspecies occupy a combined range extending from Senegal in the west to Mozambique in the south-east. Adult males differ notably in plumage coloration among races, as demonstrated by the three subspecies seen here. The lower breast, belly and vent vary from white through two shades of yellow to scarlet, while the male of one race has a metallic green throat, rather than the purple-blue of the other four. In addition to the racial differences, male Variable Sunbirds also go through immature and seasonal plumages. Both of these are similar to the duller plumages of the females, although the eclipse-plumaged male may retain some metallic feathers. Interestingly, some populations of at least two subspecies may lack an eclipse plumage.

tongue that is rolled along the sides to form two tubes, bifurcated towards the tip, which consists of two spiral non-fimbriated tubes. In *Cinnyris*, the edges are rolled inwards for most of the length, creating two tubes that separate towards the tip and end in short spikes. In *Aethopyga*, the rolled lateral tubes diverge towards the tip, leaving a narrow central area, which is split to form two spikes, and the lateral tubes end as points, with slightly fimbriated inner edges, producing an overall impression of a narrower *Hypogramma*-like tongue. The tongue of *Arachnothera*, the spiderhunters, forms a perfect tube for most of its length, being bifurcate towards the tip, which consists of two incomplete tubes with much-fimbriated inner edges.

The long bills and tubular tongues possessed by both the hummingbirds (Trochilidae) and the sunbirds may have co-evolved with tubular flowers, whereas the brush tongues of the honeyeaters, which allow them to gather nectar and honeydew over large surfaces, placed no such constraint on plants. The hyoid arms are long and elastic, arising close to the glottis, and they pass up the occiput and, as with woodpeckers (Picidae), are inserted at the base of the upper mandible, above an imaginary line drawn between the eyes.

The oesophagus is narrow and non-distensible, and there is no crop, and thus, unlike the condition in hummingbirds, no place for storage of nectar. The glandular proventriculus is rather variable in its form. In *Chalcomitra* it is a thin-walled sac, only slightly broader than the oesophagus, and hardly distinguishable from it. In the Western Violet-backed and Golden-winged Sunbirds, of the respective genera *Anthreptes* and *Drepanorhynchus*, it is also thin-walled but has a very much larger lumen, and is much broader than the oesophagus. The proventriculus of *Leptocoma*, *Nectarinia* and *Arachnothera* is slightly broader and slightly thicker-walled than the oesophagus. In another *Anthreptes* species, the Brown-throated Sunbird, the lumen is obviously larger, and the walls much thicker than the oesophagus; this condition is found also in species in the genera *Chalcoparia*, *Deleornis*, *Anthodiaeta*, *Hypogramma*, *Anthobaphes*, *Cyanomitra*, *Cinnyris* and *Aethopyga*. Thickened proventricular walls, which may be more muscular, perhaps indicate a diet less dependent on nectar and more dependent on arthropods and/or fruit. The difference in the structure of the proventriculus between the two species of

Anthreptes may indicate that the Asian and African members of this genus represent separate lineages.

Nectariniids have short, sturdy, scutellate tarsi that terminate in short, strong toes with sharp nails. The wing is rounded, and has ten primaries, the outermost of which is much reduced. The tail, with twelve rectrices, may be square, rounded or graduated, and the males of some species have the central rectrices elongated.

Sexual dimorphism is fairly well marked in the Nectariniidae. The males are larger than the females, and their plumage generally exhibits much iridescence, which is absent or greatly reduced in the plumage of females. In species which display little or no sexual dichromatism, both sexes tend towards a female-type plumage with very small areas of iridescence or none at all, as illustrated by the Little Green, Eastern Olive and Grey-hooded Sunbirds (*Aethopyga primigenia*) and the spiderhunters. Four species which lack sexual dichromatism or in which this is reduced have plumage that is not of female type. These four are Reichenbach's, Sao Tome, Cameroon and Blue-headed Sunbirds.

Pectoral tufts may be possessed by males alone, by both sexes or by neither sex. They are found in about 54% of the sunbirds and spiderhunters, but in less than 5% do they occur in both sexes. Among the species in which both sexes have tufts, those of the female are usually less bright than the male's and are reduced in size. Pectoral tufts range in colour from white or grey to yellow, orange or some shade of red, or are a mixture of two or even three colours. They are absent in the monotypic genera *Chalcoparia*, *Hypogramma*, *Dreptes* and *Drepanorhynchus*. In both species of *Deleornis* they are present only on the males. Ten of the 14 species of *Anthreptes* have tufts, but in the male plumage only, except in the case of the Violet-tailed Sunbird, both sexes of which possess them. Two of the four species of *Anthodiaeta*, namely the Collared and Amani Sunbirds, also have tufts, once again confined to the males. Only one of the three *Anabathmis* species has them, and likewise only in the male plumage, and the monotypic genus *Anthobaphes* similarly has pectoral tufts in males alone. All eight species in *Cyanomitra* have pectoral tufts, but only in two, the Eastern Olive and the Mouse-coloured Sunbirds, are they present in both sexes. One species of *Chalcomitra*, the Carmelite Sunbird, carries such adornments;

Sunbird moult patterns are complex, with variation between and within species. The males of some species have an intermediate immature plumage, into which they moult after the juvenile stage but before assuming definitive adult dress.

The males of some species have a distinct eclipse plumage outside the breeding season, in which they lose their more spectacular colours and assume female-type coloration. The male **Southern Double-collared Sunbird** has such a plumage, being mainly grey-olive but retaining a metallic sheen to the lesser wing-coverts and upperparts, plus isolated metallic feathers on the head and remnants of a red breastband.

[*Cinnyris chalybeus*
chalybeus,
Kirstenbosch, Cape Town,
South Africa.
Photo: Peter Ryan]

The second most speciose genus in the Nectariniidae is *Aethopyga*, with all of its 18 species residing in tropical Asia. These are rather svelte sunbirds with a relatively long, decurved bill and a long, graduated tail. The effect of the tail is augmented in the males of most species, because they have elongated central rectrices. Members of this genus are sexually dichromatic, with the female less resplendent in plumage than the male. While there is substantial variation in plumage coloration across the genus, males of all species are united in having a bright yellow area in the region of the lower back and rump. The genus contains four superspecies, one being formed by the **Crimson Sunbird** and Vigors's Sunbird (*Aethopyga vigorsii*), which until recently were considered conspecific. The male **Crimson Sunbird** is a striking bird, mainly crimson with a purple-blue or purple-green forehead, lores, moustachial stripe and central tail feathers. The male **Green-tailed Sunbird** displays a greater variety in colour than the **Crimson Sunbird**. It shares a yellow-chestnut breast, belly and undertail-coverts with several congeners, and has maroon neck sides and upper mantle, with a green or blue-green head, darkest on the throat.

Photo: Kanit Khanikul]

The ten species of spiderhunter are all placed in the genus *Arachnothera*. Unlike the more widespread sunbirds, spiderhunters occur only in tropical Asia. Morphologically, the genus is rather homogeneous. All species are rather stocky and most are considerably larger than most sunbirds: the heaviest spiderhunter weighs as much as twelve times the lightest sunbird on record. The bill of the spiderhunters is long or very long, as in the case of the **Little Spiderhunter**, and is at least twice the head length. It is decurved and rather deep-based, narrowing only gradually towards the tip; there is a basal ridge between the two nostrils. The Little Spiderhunter is one of four members of its genus to have pectoral tufts.

[*Arachnothera longirostris*
cinireicollis,
Fraser's Hill, Malaysia.
Photo: John & Jemi
Holmes]

its congener the Amethyst Sunbird occasionally does so, but in this case the tufts are restricted to males. Males of two of the five species of *Leptocoma*, the Crimson-backed and Copper-throated Sunbirds, have tufts, but these are not possessed by the females in this genus. Of the six *Nectarinia* species, males of the Malachite and Red-tufted Sunbirds, and the female of the latter species, are so adorned. Although 36 species of *Cinnyris* have pectoral tufts, they are present in the females of only three. Fifteen *Aethopyga* species are without tufts and, of the three species that do possess them, namely the Apo Sunbird, Lina's Sunbird and the White-flanked Sunbird (*Aethopyga eximia*), only the last has them in both sexes. Finally, in the genus *Arachnothera*, males of the Little (*Arachnothera longirostris*), Thick-billed (*Arachnothera crassirostris*), Long-billed and Yellow-eared Spiderhunters (*Arachnothera chrysogenys*) have pectoral tufts; the remaining six spiderhunter species lack them completely.

Another character in which the sexes may differ is that of tail length. In 21 species of sunbird divided among the genera *Anthodiaeta*, *Anthobaphes*, *Nectarinia*, *Drepanorhynchus*, *Cinnyris* and *Aethopyga*, the males have the central tail feathers elongated, whereas the females do not. Examples are the Pygmy, Orange-breasted, Tacazze, Golden-winged, Beautiful and Gould's Sunbirds (*Aethopyga gouldiae*). In the case of the Crimson Sunbird, the males of some subspecies have elongated central tail feathers, but those of other races do not. The male Fork-tailed Sunbird (*Aethopyga christinae*) has two prongs that project some way beyond the end of the tail, this feature being absent in the female. In three other *Aethopyga* species, the Lovely, Handsome and Vigors's Sunbirds, the tail of the male is somewhat longer and is much more graduated than that of the female.

An immature plumage has been described for the majority of the members of the family, and in all cases this differs from the adult plumage. When the adults exhibit sexual dichromatism, the immatures tend to resemble females. The differences may be very slight, as with the Grey-headed, Pygmy and Moreau's Sunbirds

and the Little Spiderhunter, or they may be more obvious, as with Anchieta's, Carmelite and Fork-tailed Sunbirds. In 24 species, among them the Violet-breasted, Regal and Green-headed Sunbirds, the young bird is markedly different in plumage from the adults of both sexes.

Moult regimes of the Nectariniidae are varied, and not fully known. The males of some species do not have an intermediate immature plumage but, instead, moult directly from juvenile to breeding plumage. They do, however, have a non-breeding plumage, which they acquire between periods of breeding. Examples of such species include, among others, the Crimson-backed Sunbird, the nominate race but not the subspecies *dartmouthi* of the Red-tufted Sunbird, the Golden-winged Sunbird, 16 species of *Cinnyris*, including the Black-bellied (*Cinnyris nectarinioides*), Dusky (*Cinnyris fuscus*) and Purple Sunbirds (*Cinnyris asiaticus*), and, in the genus *Anthodiaeta*, the Pygmy and Nile Valley Sunbirds. The males of other species have a juvenile or immature plumage, but no special non-breeding dress. This situation is illustrated by, for example, the Angolan population of Bocage's Sunbird but not the Congolese one, by Moreau's Sunbird and its congeners the Splendid (*Cinnyris coccinigastrus*), Shining, Pemba and Regal Sunbirds, by four *Chalcomitra* species, namely the Amethyst, Green-throated, Scarlet-chested and Hunter's Sunbirds, and by the Fire-tailed Sunbird.

In yet other species, the males have no intermediate immature plumage and no distinct non-breeding plumage. This is a characteristic of, for example, the Ruby-cheeked Sunbird, both species of *Deleornis*, the Purple-naped Sunbird, the Bronze Sunbird, the Golden-winged Sunbird, 22 *Cinnyris* species, including Neergaard's (*Cinnyris neergaardi*), Rockefeller's (*Cinnyris rockefelleri*) and Johanna's Sunbirds (*Cinnyris johannae*), probably all species of *Cyanomitra* except perhaps the Mouse-coloured Sunbird, the Socotra Sunbird in the genus *Chalcomitra*, the Collared and Amani Sunbirds in *Anthodiaeta*, all species of *Anthreptes* except perhaps the Straight-billed Green Sunbird, all species of *Leptocoma*, probably all *Aethopyga* ex-

cept the Fire-tailed, Crimson and Vigors's Sunbirds, and all of the spiderhunters.

The males of some nectariniids have an immature plumage and also a non-breeding plumage. Examples are, in the genus *Nectarinia*, the Congolese population of Bocage's Sunbird, and the Purple-breasted, Malachite and Tacaze Sunbirds, and, in *Cinnyris*, the Beautiful, White-breasted and Variable Sunbirds. Vigors's Sunbird and the Crimson Sunbird have an intermediate plumage that could be interpreted as being a transitional stage, rather than being a discrete plumage, but they both lack a distinct non-breeding plumage.

It is not known to which group the Principe and Newton's Sunbirds belong. In general, those species associated with ever-green forest and having less seasonally affected nesting periods tend not to have a recognizable non-breeding plumage. The groups are not clear-cut, however, and it is difficult to assign most species of *Chalcomitra* to any particular category.

Habitat

The Nectariniidae as a whole are generalists in terms of their habitat requirements. Members of this family can be found from sea-level up to at least 4900 m. Some, such as the Greater Double-collared Sunbird, are recorded from both lowlands and highlands, and many inhabit a considerable range of altitudes. The Palestine Sunbird, for example, is recorded from sea-level to 3200 m. The elevational range of a species can vary depending on geographical distribution. This is demonstrated by the Malachite Sunbird, the known range of which is from sea-level to 3000 m, but this sunbird is usually found above 2000 m, and only in South Africa does it descend to sea-level. The Western Violet-backed Sunbird normally occurs below 1000 m, but in southern Africa it is usually found above 1000 m. The altitudinal levels occupied by nectariniids in the Himalayan ranges may depend on season. As examples, Gould's Sunbird is generally

present at 1200–4300 m, but is found at 330–2700 m during the winter months, and the Fire-tailed Sunbird lives at 3000–4900 m, but in winter occurs at 610–2900 m. Another species of wide altitudinal range is the Green-tailed Sunbird (*Aethopyga nipalensis*), occurring at 300–3700 m for much of the year, but in winter leaving the higher parts of the mountains for the less harsh conditions at lower levels.

Twelve species, including the Red-throated, Buff-throated, Apricot-breasted and Flame-breasted Sunbirds, have not been recorded above 1000 m, and some species are confined to islands of low elevation. Fifteen sunbird species, including the Socotra, Hunter's, Black and Metallic-winged Sunbirds (*Aethopyga pulcherrima*), and two spiderhunters, the Thick-billed and Grey-breasted Spiderhunters, range from sea-level to between 1200 m and 1500 m, depending on species. A further 13 species of sunbird and four of spiderhunter are recorded from "lowlands" to various altitudes up to a maximum of 2000 m, some of them not unequivocally stated as reaching sea-level; examples are the Scarlet-tufted, Newton's, Shining and Temminck's Sunbirds and the Streaky-breasted Spiderhunter. Ten sunbirds and two spiderhunters are found from the lowlands up to between 2100 m and 2400 m, these including the Long-billed Green, Loten's (*Cinnyris lotenius*) and Crimson-backed Sunbirds and the Little Spiderhunter.

Several nectariniids are described as "montane" species, but with no precise altitudinal ranges recorded. These are the Sao Tome, Montane Double-collared, Eastern Double-collared and Rufous-winged Sunbirds. Seven sunbirds, including the Orange-tufted, Ursula's, Apo and Javan Sunbirds, and Whitehead's Spiderhunter (*Arachnothera juliae*) have a minimum recorded altitude of between 700 m and 950 m. A further seven, among them the Bronze and White-flanked Sunbirds, are not known to occur below 1000 m, and two others, the Black-throated (*Aethopyga saturata*) and Gould's Sunbirds, occur below this level only in winter. Moreau's Sunbird lives at 1300–1850 m and the Regal Sunbird at 1500–3100 m, whereas Bocage's Sunbird is

Whereas many species of sunbird are brightly coloured, spiderhunters have predominantly fairly dim olive-green plumage. Five spiderhunter species have relatively unmarked plumage, with patterning restricted to orbital rings or other areas of the head. The other five have streaked plumage, the intensity and extent of which varies between species. The **Streaked Spiderhunter** has heavy black shaft streaks on both upperparts and underparts. This species has five races, but these are poorly differentiated, with variation restricted to subtle plumage tones and clarity of streaking. The race *pagodarum*, seen here, is of questionable validity, as it may not be sufficiently diagnosable.

[*Arachnothera magna pagodarum*, Fraser's Hill, Peninsular Malaysia. Photo: Ong Kiem Sian]

The nectariniids exhibit substantial sexual dimorphism, males being larger than females. The majority of sunbirds, but not spiderhunters (Arachnothera), are also sexually dichromatic. In such sunbirds, males are more brightly coloured than females and usually exhibit areas of feathering with a distinct metallic sheen or iridescence. In some species, the female also has some iridescent plumage, but usually over a smaller area.

A good example is the **Green-headed Sunbird**, which occurs from Senegal east to Malawi. Both sexes have olive-coloured upperparts and grey underparts, but they differ in the extent of iridescence. The male (left) has the entire head, nape, throat and upper breast metallic blue-green.

The female (right), in contrast, has the throat and upper breast more or less concolorous with the remainder of the underparts.

[*Cyanomitra verticalis viridisplendens*, Semliki NP, Uganda. Photos: G. & Y. Dean/World Wildlife Images]

found mainly around 1500 m. A minimum altitude of 1800–1900 m is noted for four African species, these being the Blue-headed, Tacazze, Purple-breasted and Prigogine's Double-collared Sunbirds, and neither Rockefeller's Sunbird nor Stuhlmann's Double-collared Sunbird has been observed below 2000 m.

Seventeen sunbirds, including the Copper, Souimanga and Purple Sunbirds, and three spiderhunters, including Whitehead's, reach their maximum altitude somewhere between 2100 m and 2400 m. The Collared, Cameroon, Variable and Northern Double-collared Sunbirds do not ascend above 2600–2800 m. At higher elevations, seven species reach between 3000 m and 3300 m, examples being the White-flanked, Palestine and Rockefeller's Sunbirds. Only six members of the family have been found at 3700 m or above. The Green-tailed and Stuhlmann's Double-collared Sunbirds reach that altitude, and the Tacazze Sunbird ascends to 4200 m, Gould's Sunbird to 4300 m, the Red-tufted Sunbird to 4500 m and the Fire-tailed Sunbird to 4900 m.

With regard to habitat choice, the majority of the species are very catholic in their preferences and are opportunistic. If flowering plants providing nectar and invertebrate prey are present within the family's altitudinal and geographical ranges, then sunbirds and spiderhunters are likely also to be present. A few species are generally found only in association with forests, this being typical of, for instance, the Grey-headed, Blue-headed, Purple-breasted, Rufous-winged, Grey-hooded and Apo Sunbirds, as well as Whitehead's Spiderhunter. Some nectariniids, such as Anchieta's Sunbird, are restricted to more open forms of wooded country. Certain species are normally found only in more open habitats such as savanna or scrub, examples of these being the Nile Valley, Hunter's, Greater Double-collared, Beautiful and Black-bellied Sunbirds, or, in a few cases, in association with water, as illustrated by the Violet-tailed, Reichenbach's and Congo Sunbirds.

Most members of the family occupy a variety of habitats. The preferred habitat of those having extensive continental ranges or occurring over large archipelagos may vary geographically. For example, the Western Violet-backed Sunbird in West and

East Africa occurs in acacia (*Acacia*) woodland, in gallery forest running through savanna, and in mangroves and gardens, but in Zambia it is normally found only in miombo woodland, and in Angola, Malawi and Zimbabwe in miombo and *Uapaca* woodland. Similarly, the Northern Double-collared Sunbird occurs in heathland on Mount Cameroon and Bioko, whereas in East Africa it prefers forest, plantations and gardens. Most nectariniids are tolerant of man-made or man-influenced habitats, and many appear to thrive in such situations, as demonstrated by, for example, the Ruby-cheeked, Brown-throated, Olive-backed and Seychelles Sunbirds. For a few, such as the Rufous-winged Sunbird, there is no documented evidence for the usage of habitats created by human activities, but this is usually due to the fact that the distribution of these species is extremely restricted and the opportunity has not yet presented itself. The Socotra and Pemba Sunbirds occupy all habitats within their respective single-island ranges, and the Black Sunbird is similarly catholic in its habitat selection on the south Moluccan island of Buru, although it avoids the interior of forests.

Ninety-five species have been recorded in primary forest, and 26–30 of these do not occur in secondary forest. Only five of the 60 or so species known from secondary forest have not been seen in primary forest. Twelve species are restricted, or almost restricted, to forest-edge habitats and are absent from the interior.

Members of the Nectariniidae exploit all available forest types, at all elevations, within the distributional area of the family. Lowland dipterocarp forest is utilized by nine Asian species, including the Ruby-cheeked and Temminck's Sunbirds and the Thick-billed Spiderhunter. The same number can be found in hill dipterocarp forest, and there is some overlap in species, but three of them, the Javan Sunbird and the Streaky-breasted and Whitehead's Spiderhunters, are known from this higher-elevation forest but not from lowland dipterocarp. Lower montane or submontane forest holds 15 species in each of the Afrotropical and the Oriental Regions, and in Asia includes some species also occurring in hill dipterocarp. African species living in forest at this altitude include the Uluguru Violet-backed, Sao Tome and Montane

Although foraging and parental duties take up the bulk of their time, all birds set aside time each day for preening. During the day's work, feather barbs that normally interlock may become disengaged or tangled. Preening is essential for repairing damage to feathers and for ensuring that they are in optimal condition for flying. This **Purple-throated Sunbird** is rectifying a problem with the underside of its secondaries, to which it gains access by raising its wing. It is a female, as evidenced by its largely olive and yellow plumage. The male of the race shown here (*brasiliensis*) differs from the nominate by dint of its black mantle; metallic purple-blue rump and shoulder patch; and maroon breast and upper belly.

Eriksen]

Double-collared Sunbirds. No fewer than 26 nectariniids inhabit montane forest, examples including the Cameroon and Apo Sunbirds and the Streaked Spiderhunter (*Arachnothera magna*), but some, such as the Bronze and Golden-winged Sunbirds, occur only at the edge and do not penetrate the interior. A few, such as the Green-tailed and Fire-tailed Sunbirds, also reach upper montane forest. In Asia, alluvial forest has much the same selection of species as lowland dipterocarp, although one species found in the former, the Copper-throated Sunbird, is not present in lowland dipterocarp. In the Oriental Region, peat-swamp-forest, harbouring twelve species, overlaps in its species content with lowland dipterocarp forest, but species such as the Purple-throated and Crimson Sunbirds are more likely to be found in peat-swamp than in lowland dipterocarp.

Seventeen species of sunbird are found in African gallery forest. Four of these, the Western Violet-backed, Blue-throated Brown, Green-throated and Scarlet-chested Sunbirds, occur where such forest runs through savanna. Riverine or riparian forests may be utilized by Plain-backed, Uluguru Violet-backed, Violet-tailed, Bannerman's, Mouse-coloured, Western Olive, Amethyst, Mariqua, Congo, Common Purple-banded and White-breasted Sunbirds in Africa, and in the highlands by the Blue-headed Sunbird. Such forests in Asia are home to the Brown-throated, Purple-naped, Purple-throated, Olive-backed and Crimson Sunbirds.

Twenty-four species of sunbird and two of spiderhunter make regular use of mangroves, particularly *Avicennia* and *Rhizophora* stands, and a third spiderhunter has been recorded once in this habitat. Only the Mouse-brown Sunbird, however, seems to favour mangroves over other habitats where a choice is available. Other species commonly associated with this habitat include the Plain-throated, Violet-tailed, Copper-throated and Olive-backed Sunbirds. It is frequently the case that the species found in mangroves also favour disturbed and degraded habitats and secondary growth.

Kerangas forest, often referred to as "heath forest" although it contains no heathers (Ericaceae), is a well-drained forest type growing on coarse, sandy, podzolic soils in South-east Asia, and the very similar kerapah forests, which have impeded drainage, are characterized by a few species of dipterocarp tree and, sometimes, the large conifer *Agathis*. These forests are known to har-

bour five species of sunbird, including the Purple-naped and Copper-throated Sunbirds, and the Little Spiderhunter. Another habitat in this region, *Melaleuca* forest, is utilized, at least at times, by the Ruby-cheeked, Plain-throated, Purple-throated and Crimson Sunbirds. Asian coniferous forests are used only by Gould's and Fire-tailed Sunbirds and Long-billed Spiderhunters. Coastal forest or strand forest is frequented by the Ruby-cheeked, Brown-throated and Plain Sunbirds and the Grey-breasted Spiderhunter in Asia, and by the Collared, Blue-throated Brown, Mouse-coloured and Southern Double-collared Sunbirds in Africa. Asian deciduous forests form part of the known habitat of Purple, Gould's, and Green-tailed Sunbirds, as well as that of the Little and Streaked Spiderhunters.

In Africa, Violet-tailed and Prigogine's Double-collared Sunbirds occur in alluvial forest and Bannerman's and Common Purple-banded Sunbirds in moist evergreen forest, while the Streaked Spiderhunter is known from the latter habitat in Asia. African freshwater swamp-forests are utilized by Violet-tailed and Straight-billed Green Sunbirds, and the Mariqua Sunbird is found at the edges; the Purple-naped Sunbird exploits this habitat in Asia. The Eastern Olive Sunbird in Africa may be found in dune-forests, and in the same continent *Hagenia-Hypericum* forest may hold Red-tufted and Stuhlmann's Double-collared Sunbirds and *Cryptosepalum* forest the Miombo Double-collared Sunbird. Dry forests are home to the Common Purple-banded Sunbird in Africa, the Long-billed Green Sunbird in Madagascar and the Purple Sunbird in Asia.

Secondary forest and other secondary growth form part of the habitat of at least 60 members of the family. The Long-billed Spiderhunter is only occasionally found in such habitat, whereas some species, such as the Straight-billed Green Sunbird, select it in preference to primary forest. The disturbed nature of such areas results in a greater abundance and more constant supply of plants in flower, particularly herbs and bushes, than would be found within primary forest, hence making secondary growth more attractive to nectariniids. Similarly, forest edge and clearings are often more productive for this family than the forest interior, where flowering herbaceous plants are far less common, while tree flowers are high in the canopy, and epiphytes are much less reliable sources of nectar or invertebrates. More than 70 species of sunbird and spiderhunter are found at edges or in clearings.

This **Yellow-eared Spiderhunter** has found a suitable perch on which to rest and preen. Preening is the most basic form of feather care. Birds use their bill to restore feather structure, clean their plumage, apply oil from the uropygial gland above the rump, or simply realign displaced feathers. This spiderhunter is attending to feathers on its breast sides and flanks. Its long bill means that it has to go through various contortions to reach the desired spots. Depending on the type of maintenance needed, the bird will use its bill in one of two ways: it will either "nibble" the feather gently; or wipe the bill across its surface. Nibbling seeks to restore the placement of barbs and barbules, remove foreign bodies or stale oil, or apply fresh oil. Wiping serves to rearrange or dry feathers, or to coat them with uropygial oil.

[*Arachnothera chrysogenys*
chrysogenys,
Mandai, Singapore.
Photo: Teo Nam Siang]

Throughout the range of the family, various types of woodland are utilized by a wide variety of sunbirds, as well as by the Little Spiderhunter. In the Afrotropics, Newton's Sunbird is found in woodland, but only on steep hillsides; Neergaard's Sunbird occupies dry woodland, whereas the Greater Double-collared

Sunbird prefers damper conditions such as are found in coastal woodland, where the Carmelite Sunbird may also be found, and the Mariqua Sunbird inhabits acacia-mopane woodland. The last-mentioned is home also to seven other species, although the Tsavo Purple-banded Sunbird occurs in such habitat only along rivers. *Uapaca* woodland is recorded as a habitat for the Western Violet-backed and Collared Sunbirds. *Brachystegia-Isoberlinia*-miombo woodland is exploited by about 15 African nectariniids, including the Banded, Bannerman's, Scarlet-chested, Bocage's, Miombo Double-collared, Shelley's and Oustalet's Sunbirds, and *Baikiaea* woodland provides a habitat for the Amethyst, Bocage's and Shelley's Sunbirds. Riverine woodland is occupied by the Kenya Violet-backed, Bannerman's, Miombo Double-collared, Southern Double-collared and Copper Sunbirds in Africa, but in Asia evidently only by the Little Spiderhunter. Asian deciduous woodlands are exploited by Purple-rumped and Vigors's Sunbirds, and the latter can be found also in evergreen woodland. In the African continent, highland acacia woodland claims the Tacazze Sunbird as a denizen, whereas highland *Leucospermum* woodland harbours the Miombo Double-collared Sunbird. Juniper (*Juniperus*) woodland may attract the Palestine Sunbird, which sometimes enters *Cupressus* groves, and casuarina (*Casuarina*) groves in Asia occasionally host the Brown-throated Sunbird. Several species occur in natural coconut (*Cocos nucifera*) groves, three in Africa and nine in Asia, and ten have been recorded in coconut plantations, among them the Crimson Sunbird and the Spectacled Spiderhunter (*Arachnothera flavigaster*), both of which are found also in natural coconut groves. Nine species have been observed in bamboo in Africa, namely the Tacazze, Malachite, Red-tufted, Golden-winged, Stuhlmann's Double-collared, Regal, Rockefeller's, Eastern Double-collared and Loveridge's Sunbirds, and two in Asia, the Elegant Sunbird (*Aethopyga duyvenbodei*) and the Little Spiderhunter.

Thick bush and various types of scrub, including scrub-jungle and thorn-scrub, attract 25 species of sunbird in Africa, where such habitats are more widespread, and ten sunbirds and two spiderhunters in Asia. In the former continent, the list includes the Nile Valley, Green-headed, Shining, Oustalet's, Humblot's

Scratching is a common form of comfort behaviour among birds. It is a natural response to a minor irritation, such as an itch. Scratching also assists with preening, enabling a bird to realign feathers. Headscratching, as demonstrated by this **Red-chested Sunbird**, may also be important during moult, serving to dislodge and remove old feathers. Arboreal birds, such as nectariniids, tend to scratch their heads by the "indirect method", which involves extending the leg over the wing. In contrast, terrestrial birds tend to headscratch using the "direct method", reaching to the head from under the wing. Ornithologists once thought that each species used only one of the two methods, which could thus serve as a taxonomic tool, a suggestion that was undermined when many species were found to deploy both methods.

[*Cinnyris erythrocerus*,
Queen Elizabeth
National Park, Uganda.

World Wildlife Images]

Nectariniids are rather vocal birds, frequently calling to announce their arrival at a new foraging spot, or to communicate among social groups. While not effusive songsters, sunbirds and spiderhunters do sing to attract mates and defend territories. The rather complex song of the **Amethyst Sunbird** comprises rapid twittering that ascends and descends. While singing tends to be the prerogative of the male nectariniid, females of some species also sing. Indeed, members of an Amethyst Sunbird pair will duet, the female warbling in response to the male's more forthright vocal outpouring. The bird seen here can be sexed as a male on account of its black plumage with small iridescent areas.

[*Chalcomitra amethystina amethystina*, Modimolle, Limpopo, South Africa. Photo: Warwick Tarboton]

and Dusky Sunbirds, and in Asia the Apricot-breasted and Flame-breasted Sunbirds and the Naked-faced (*Arachnothera clarae*) and Streaked Spiderhunters.

Low beach or coastal vegetation, as distinct from woodland or forest, is a recorded habitat of the Ruby-cheeked Sunbird, three *Anthreptes* species, two of *Leptocoma*, one *Cinnyris* sunbird and the Grey-breasted Spiderhunter in Asia, and of ten African species, although one of the latter, the Dusky Sunbird, is found in such habitat only in arid areas. The Southern Double-collared Sunbird is known to use dune-thickets in Africa.

High-altitude montane thickets and scrub attract Western Olive, Bronze, Olive-bellied, Greater Double-collared, Regal and Montane Double-collared Sunbirds in Africa, whereas similar habitats in Asia are utilized by four members of the genus *Aethopyga*, namely the White-flanked, Green-tailed, Black-throated and Fire-tailed Sunbirds. The Montane Double-collared Sunbird can be found also in high-altitude bracken-briar. Highland scrub, including *Hypericum*, is colonized by the Red-tufted, Stuhlmann's Double-collared, Olive-bellied, Greater Double-collared and Regal Sunbirds in Africa, and in the same continent Afro-alpine grassland, moorland and heaths are home to nine nectariniids, including the Green-throated, Tacazze, Malachite and Red-tufted Sunbirds, and, where there are bushes, the Golden-winged and Bronze Sunbirds also may occur. In southern Africa, protea (*Protea*) moorland is a habitat of the Malachite, Red-tufted and Southern Double-collared Sunbirds, and Red-tufted Sunbirds can be found also in protea grassland. The Kenya Violet-backed Sunbird occurs in juniper at highland forest edge.

A variety of more open habitats is favoured by a host of sunbirds and a few spiderhunters. "Open country" in general is recorded as a habitat of the Greater Double-collared, Olive-backed, Mayotte (*Cinnyris coquerellii*) and Crimson Sunbirds. Various forms of savanna are inhabited by some 23 members of the family in Africa, one of these being found in similar surroundings also in the Middle East. The list includes the Mouse-brown, Collared, Carmelite, Amethyst, Scarlet-chested, Greater Double-collared, Kenya Violet-breasted, Palestine, Splendid and Copper Sunbirds. Gallery forest running through savanna may be utilized by the Western Violet-backed Sunbird. Wooded savanna

attracts the Violet-tailed, Pygmy, Newton's, Green-headed, Orange-tufted, Olive-bellied and Superb Sunbirds, whereas the Miombo Double-collared Sunbird prefers more open savanna. The Red-chested Sunbird can be found in savanna near water, whereas the Black-bellied Sunbird prefers acacia savanna, and the Tsavo Purple-banded Sunbird savanna with acacia and

Whereas the songs of many sunbirds are relatively simple, those of the genus *Cinnyris* are frequently more complex and last longer. The song of the **White-breasted Sunbird** fits this mould, comprising a melodic warble and a trill framed on either side by a variety of abrupt notes. This sunbird is also one of just a handful that have the ability to mimic other birds. Species that feature in the White-breasted Sunbird's versatile repertoire include the Common Bulbul (*Pycnonotus barbatus*), the Chestnut-vented Warbler (*Sylvia subcaerulea*), two species of *cisticola* (*Cisticola*) and the Bronze Mannikin (*Lonchura cucullata*), all of which inhabit the White-breasted Sunbird's domain in the woodlands, gardens and parks of the southern half of sub-Saharan Africa.

[*Cinnyris talatala*, Kruger National Park, South Africa. Photo: Alejandro Torés]

Cinnyris sunbirds often have relatively complex songs. In comparison, the song of **Stuhlmann's Double-collared Sunbird** is perhaps rather uninspired. It comprises a warble that rises in tone shortly before the end prior to descending. Singing from an exposed perch provides the bird with the opportunity to display its spectacular plumage and, in this case, its vivid yellow pectoral tufts, which are otherwise usually concealed. Stuhlmann's Double-collared Sunbird is one of 16 species of double-collared sunbird and forms a superspecies with Prigogine's Double-collared Sunbird (*Cinnyris prigoginei*) and the Montane Double-collared Sunbird (*C. ludovicensis*).

Commiphora. The Variable Sunbird is found in a variety of savanna types, including montane, and forest-grassland mosaic attracts several species, among them the Little Green, Green-headed and Tiny Sunbirds.

Dry and semi-arid bush country is favoured by the Kenya Violet-backed, Pygmy, Nile Valley, Scarlet-chested, Socotra, Southern Double-collared, Neergaard's, Mariqua, Palestine, Variable and Dusky Sunbirds, and the Beautiful Sunbird may sometimes be seen near water in such habitat. Only three species, the Dusky, Nile Valley and Souimanga Sunbirds, can be found in semi-desert. The Common Purple-banded and Orange-tufted Sunbirds occur in grassland with moderate rainfall, but in drier semi-arid grassland Hunter's and Variable Sunbirds can be seen. In southern Africa, fynbos holds very few nectariniids, one of which, the Orange-breasted Sunbird, is almost restricted to this habitat. Also in southern Africa, karoo vegetation is used by the Malachite Sunbird, while the Greater Double-collared Sunbird may be found in areas of succulents, and the Orange-breasted Sunbird occasionally wanders into such places. Low riverine vegetation may be host to 15 or so sunbird species, including the Sao Tome, Black, Prigogine's and Black-throated Sunbirds, and the Little Spiderhunter. In dry country, the Black-bellied and Dusky Sunbirds also occur in such habitat.

Marshes and open swamps can provide habitats for Brown-throated, Collared, Purple-naped, Red-chested, Carmelite and Copper Sunbirds, and in places where such habitats are mixed with grassland the Red-chested Sunbird may occur. In marshes with bushy edges Bocage's and Bronze Sunbirds can be found, and coastal swamps are utilized by the Mouse-brown Sunbird.

Cultivations and gardens attract at least 75 nectariniid species, although one of these, Johanna's Sunbird, is only rarely recorded in such habitats, and another, the Fork-tailed Sunbird, is said to be only an occasional visitor to them. The abundance of flowering plants provides a cornucopia of nectar and invertebrate prey, and it is probable that any member of the family will eventually be found to take advantage of such food sources as humans encroach more upon their natural habitats.

Fifty species of sunbird and spiderhunter are known to occur in plantations, the majority probably attracted to the same

food sources as they would otherwise find in secondary or primary forests. In many, if not most, cases, the other forms of secondary growth associated with the plantation, rather than the crop plants themselves, are probably the chief attraction. Rubber, particularly older, abandoned plots, hosts ten species. As this crop is grown more widely in Asia than in Africa, the majority of these ten are Asian, such as the Plain and Purple-naped Sunbirds and the Spectacled Spiderhunter. Similarly, *Albizia* is a plantation species in Asia, where six sunbirds and five spiderhunters, including the Ruby-cheeked Sunbird and the Thick-billed and Long-billed Spiderhunters, have been recorded as utilizing it. Cocoa plantations are exploited by eleven species of sunbird, only three being Asian, reflecting the greater presence of cocoa in Africa than in Asia. Seven African species, including the Cameroon and Tacaze Sunbirds, and the Long-billed Green Sunbird of Madagascar, can be found in exotic eucalypt (*Eucalyptus*) stands, which in Asia are visited also by three species of spiderhunter, including the Yellow-eared. Shade trees in tea plantations attract the Uluguru Violet-backed Sunbird in Africa and the Crimson-backed Sunbird in the Western Ghats of India. Coffee plantations are a recorded habitat of ten African species, including Newton's and Carmelite Sunbirds, whereas the aforementioned Indian species again utilizes shade trees in such plantations. Five species of sunbird and four of spiderhunter occur in banana plantations, reflecting the fondness of spiderhunters in general for wild plantains (*Musa*). Other types of plantation, such as oil palm (*Elaeis guineensis*), coconut, clove (*Syzygium*), acacia, *Trema orientalis*, casuarina, *Gmelina*, maize (*Zea*), nutmeg (*Myristica fragrans*), ginger (*Zingiberaceae*), cardamom (*Elettaria cardamomum*), tobacco (*Nicotiana tabacum*) and abaca (*Musa textilis*), as well as various fruit trees, mixed plantations and tree nurseries, each support one or two members of the family.

Throughout most of the range of the family, any particular habitat is likely to be utilized simultaneously by more than one species of sunbird or spiderhunter, but there is little evidence of resource-partitioning among the species. Interspecific competition has, however, been recorded on Siau, north of Sulawesi, and on Bacan, in the Moluccas, the Black Sunbird being replaced by

Flowers are the most important source of food for sunbirds and spiderhunters, so an open flower in a sunlit area quickly attracts the attentions of this male **Purple-throated Sunbird**. Sunbirds commonly visit flowers to extract nectar, as is recalled in the family's scientific name. To facilitate access to its chosen flower, the Purple-throated Sunbird may hover, perch on a branch, or even hang from the flower itself. Once in a suitable position, the sunbird inserts its bill into the flower and sucks the nectar, in contrast to hummingbirds (*Trochilidae*), which lick it. Nectariniids' internal morphology is such that, unlike hummingbirds, they are unable to store nectar, and thus must feed frequently.

[*Leptocoma sperata*

Eriksen]

the Olive-backed Sunbird at lower altitudes. Although height preferences in forests have been determined for some species, such as the Straight-billed Green Sunbird, seldom recorded below 20 m, the Banded Sunbird, living in the subcanopy and canopy, and the Purple-naped, Principe and Eastern Olive Sunbirds, all usually found low down, a considerable number of forest-dwelling nectariniids utilize all storeys; nevertheless, there is a general tendency to favour the lower levels, the higher strata being exploited only when food there becomes more abundant. The Purple-naped Sunbird, incidentally, is often more numerous in recently logged forest than in pristine forest, as the former habitat is likely to be richer in flowering herbs and shrubs. The Brown-throated Sunbird is less common than its congener the Red-throated Sunbird in plantations in South-east Asia and the Greater Sundas, where the two species are sympatric. In Africa, the Superb Sunbird is found in secondary forest more often than is Johanna's Sunbird in areas of sympatry.

In the mountains of east-central Africa, the Blue-headed and Green-headed Sunbirds are found at similar altitudes on Lendu Plateau, in north-east DR Congo, but elsewhere in its range the Blue-headed Sunbird ascends to higher elevations. The two species overlap in elevational range in the Itombwe Mountains and in the mountains west of Lake Kivu, but there appears to be no overlap at all between them on the Virungas and in Rugege Forest.

General Habits

Sunbirds and spiderhunters are diurnal nectarivores and insectivores and occasional frugivores. Members of this family are generally encountered as singletons or in pairs, or, shortly after breeding, as family groups. Their membership of bird waves, however, is also commonplace. The Grey-headed Sunbird joins such groups in forest canopies. Other interspecific socializers include the Scarlet-tufted Sunbird, at least eight species of *Anthreptes*, the Collared Sunbird, the Orange-breasted Sunbird, Newton's and Reichenbach's Sunbirds in the genus *Anabathmis*, the Green-headed, Blue-throated Brown, Western Olive and

Mouse-coloured Sunbirds in *Cyanomitra*, the Amethyst and Scarlet-chested Sunbirds in *Chalcomitra*, at least seven species of *Cinnyris* and, in the genus *Aethopyga*, the Fire-tailed Sunbird. Sunbirds also join other birds to mob potential predators, and Variable Sunbirds have been seen to mob a chameleon (*Chamaeleonidae*) in the company of babblers, bulbuls, sparrows (*Passer*), an apalis (*Apalis*), weavers (*Ploceidae*) and white-eyes.

Occasionally, sunbirds will congregate in a particular place. A tree with plentiful blossoms will attract sunbirds, as will a zone of flowering proteas or aloes (*Aloe*). Groups of White-breasted Sunbirds and Amethyst Sunbirds have been seen while migrating together, and some forest-dwelling species associate at leks (see Breeding). Sunbirds tend to fly on an undulating flightpath, often calling as they do so. Many of the forest species and the spiderhunters can be difficult to observe when they are feeding on flowers in the canopy.

Groups of conspecifics may be small, not exceeding six individuals, as is the case with, for example, the Grey-headed, Collared, Western Olive, Green-throated and Olive-bellied Sunbirds. With some other species, however, much larger groups have been recorded. Examples include flocks of 40–50 Purple Sunbirds at times when gnats (*Diptera*) are abundant; up to 60 Banded Sunbirds; up to 70 Nile Valley Sunbirds in the non-breeding season at flowering *Bombax* trees; 50–100 Orange-breasted Sunbirds outside the breeding season; up to 100 Violet-breasted Sunbirds at acacia flowers; up to 75 Shining Sunbirds together; "large congregations" of Tacazze Sunbirds at nectar sources outside the breeding season; and, somewhat astoundingly, as many as 1350 Malachite Sunbirds per hectare in areas of wild dagga (*Leonotis leonurus*), a plant known also as "lion's tail" or "lion's ear". Comparable groups have been documented for nine other species of sunbird, but no such aggregations are recorded for spiderhunters.

Apart from the period immediately after breeding, when fledglings return to their nests to roost, nectariniids do not roost communally. Those sunbird species that live at high altitudes or in places where temperatures may drop to below freezing point have evolved thermoregulatory systems enabling them to cope with cold nights. The Tacazze Sunbird, Malachite Sunbird, Eastern Double-collared Sunbird, Collared Sunbird and Orange-breasted

While flowers that have already opened evidently provide easier access to the nectar within, sunbirds are not deterred by closed flowers. They use the bill to prise apart petals, and then deploy its length and curvature to advantage in order to reach the sugar source, as this **Beautiful Sunbird** is doing.

At times, the sunbird may appear to be putting its whole head inside the flower. The **Beautiful Sunbird** has been observed visiting flowers of more than 20 plant genera, including those as varied as Jacaranda (Bignoniaceae), Acacia (Leguminosae), Aloe (Liliaceae) and Lantana (Verbenaceae). Such relatively catholic taste seems to be common amongst the Nectariniidae.

[*Cinnyris pulchellus melanogastrus*, Kenya.

Photo: Arthur Morris/ Birds As Art]

Sunbird are known to lower the body temperature by up to 17°C under field conditions. In one study of Malachite Sunbirds fitted with surgically implanted transmitters, such nocturnal hypothermia was described as torpor, a state of inactivity and reduced responsiveness. Laboratory studies have shown that, in addition, the Kenya Violet-backed, Bronze, Mouse-coloured, Buff-throated, Amethyst, Scarlet-chested, Southern Double-collared, Common Purple-banded, Variable, Bates's, Fork-tailed and Crimson Sunbirds are thermolabile, meaning that their temperature varies with that of the ambient. At ambient temperatures of 10–25°C, ten species of sunbird studied in Uganda maintained their body temperatures, and no differences in basal metabolic rate were found between forest-dwelling species and those frequenting open habitats. For the five smallest species in the study, however, thermal conductance did vary with ambient temperature. Furthermore, thermal conductance, which is a measure of how easily heat can be exchanged with the environment, being the converse of insulation, was habitat-dependent. The minimal thermal conductance of open-habitat species was significantly less than that of forest species, meaning that, at low ambient temperatures, open-habitat species need less energy than forest species to maintain constant body temperatures.

Other aspects of the behaviour of the Nectariniidae are not particularly well known, but a few details are available. After feeding, sunbirds often wipe the bill on branches or twigs. They regularly preen, and they sometimes bathe in birdbaths provided for the purpose. A Malachite Sunbird took advantage of a garden hose in order to douse itself. Anting has been recorded for a few species, including the Bronze Sunbird and the Collared Sunbird.

Voice

The arrival of a sunbird at a particular spot is usually heralded by characteristic “chip”, “tseep” or “tsk” calls, and such sounds often accompany movements of sunbirds from one foodplant to another. Other calls are uttered for contact among socially cohesive groups, by and to chicks, and in alarm. While not renowned for having melodious songs, sunbirds and spiderhunters do pro-

duce a variety of vocalizations associated with territorial defence and sexual advertisement. Songs range from short trills and whistles and frequently repeated simple notes, usually high and metallic ones, to complex melodious utterances lasting for several minutes, these latter songs being common among *Cinnyris* species. Different dialects have been identified within the standard song repertoire of certain species, such as the Splendid Sunbird, while some, including the White-breasted Sunbird, are known mimics of the songs of other birds. Among *Cyanomitra* species, social singing, with choruses by groups of assembled males in leks, is performed by, for example, the Blue-throated Brown Sunbird. Males of all sunbirds and spiderhunters sing songs, and a few also utter subsongs. In some cases, females, too, are known to sing, and duetting is a feature of the Amethyst Sunbird.

Recent research has shown that the vocalizations of flowerpeckers, sunbirds and spiderhunters carry taxonomic signals that, in general, concur with the view that the flowerpeckers are the most primitive and that the sunbirds originated in the Indian Subcontinent, rather than in Africa. This is in line with phylogenies based on mitochondrial DNA.

The song of the Ruby-cheeked Sunbird is a trill, while those of the two *Deleornis* species consist of elaborations of these birds' “tseep” or “tserr” calls. *Anthreptes* species utter high-pitched “seep” calls, and they deliver simple songs involving repetitions of notes strung together in a sequence, usually ascending and descending in pitch during the performance. One of the more vocal members of this genus is Anchieta's Sunbird, the usual song of which consists of “tseu-werr, tsoo-wit, tser-wit-tsui-tsi, chip-choo-chip, witchoo-witchoo, chip-chip, chip-up-chip-up, chipyoo-chipyoo” and variations, repeated up to 40 times. Songs of *Anthodiaeta* sunbirds are slightly more complex, involving whistles and trills.

Placed in a monotypic genus, *Hypogramma*, the Purple-naped Sunbird makes typical high-pitched “schewp” calls and repetitions of “sweet” and “tsit-tsit” notes, but its vocalizations are poorly documented. The three *Anabathmis* species produce lengthy complicated songs involving high-pitched jangling, trills, slurs and whistles. The song of the Sao Tome Sunbird, in another monotypic genus, consists of repetitions of a three-note sequence,

Giant lobelias reaching three metres in height are a characteristic sight on the slopes of Mount Kenya. Equally characteristic is the sight of a **Red-tufted Sunbird** scampering up the inflorescences of the endemic *Lobelia teleki* and *L. keniensis*, for this sunbird exploits the array of food resources offered by the lobelias. It derives nutrition directly from the plant by extracting nectar and pollen. But it also searches for spiders (*Araneae*) and insects such as bibionid flies that lurk in the plant's crevices. It even has a taste for chironomid larvae that inhabit the small water pools trapped in the rosettes of *L. keniensis*. The Red-tufted Sunbird does visit plants other than lobelias in its Afro-alpine moorland habitat at altitudes of 1900–4400 m. Other particular favourites include red-hot pokers (*Kniphofia*), aloes (*Aloe*), proteas (*Protea*), groundsels (*Senecio*) and heaths (*Erica*). The Red-tufted Sunbird derives its English name from the male's scarlet pectoral tufts, which are normally concealed beneath otherwise principally metallic dark green and black plumage. The female also has pectoral tufts, but these are much smaller than the male's, and are generally orange rather than red.

[*Nectarinia johnstoni*
johnstoni,
 Mount Kenya
 National Park, Kenya.

Feeding in flight provides an additional mechanism for sunbirds to access food resources when there is no convenient perch nearby. Some 40 nectariniids across ten genera have been observed hovering in order to feed. Many sunbirds do so to reach the nectar within flowers.

Others hover while searching for insects.

Either objective is possible for this male

Souimanga Sunbird, as the species' diet contains not only nectar but also a variety of insects, such as beetles (Coleoptera), bugs (Hemiptera) and wasps or bees (Hymenoptera). In addition to flowers, the Souimanga Sunbird hovers at spider webs, from which it steals trapped insects. It feeds in pairs, small groups and as a part of mixed-species flocks.

[*Cinnyris sovimanga* sovimanga,

Perinet Special Reserve, Madagascar.

sometimes followed by a chuckling "chut, chut, chit chit". This large island species, moreover, is one of the few sunbirds for which lekking behaviour is known; gatherings of males utter harsh "tic-tic-tic-tic-tic" sequences, followed by series of "tsi-tsu-huee, tsi-tsiu-tsiu" or "huit-huit-rruit-rruit". Males of the Orange-breasted Sunbird, in the monotypic genus *Anthobaphes*, chase each other while uttering a bell-like tinkle; they also produce a characteristic "sskrring-sskrring-sskrring" call, the females calling "sshraynk". The male's song consists of a complicated high-pitched chatter with melodious sections, whistling "piou" notes, and a descending "tzzurr" or "jeeeu" interspersed at irregular intervals. Males also have a shy subsong mixed with "sshraynk" calls. In addition, females of this species occasionally sing.

The calls of *Cyanomitra* species are "tsk" or "chuk" notes, and their songs are mostly repetitions of these notes with others, such as "tse", wheezes, trills and melodious sections. The song of the Eastern Olive Sunbird is, perhaps, the most complicated of the genus, being a protracted warble of repeated whistles, rising and falling in pitch, interspersed with melodic renditions of "tsee-tsee-tsee, tseedlee, eedlee-id-id-id-seedle, eedle-ee-ee-ee". This is another species known to indulge in lekking, the competing males singing simultaneously in a "choir" while gathered in a tree, producing a chorus of rising and falling phrases, including "sweetie weety".

Songs of species of *Chalcomitra* include many trills, and they are among the most complex of those of all sunbirds outside the genus *Cinnyris*. As an example, the song of the Green-throated Sunbird can last for as long as 4 minutes. It opens with a series of "chip" notes at a rate of six per second, these preceding a musical twittering, a 4-second series of "chi" notes at a rate of twelve per second, further twitters, bursts of "chip, chip, chip" series, then a gradually waning trill, yet more twitters, and then repeated sequences of 20 or more "chip" notes, these sometimes speeding up, and the later "chip" sequences preceded by up to nine "chouee" notes.

The vocalizations of *Leptocoma* species are generally weak, high-pitched squeaks and chirps, although the Copper-throated

Sunbird produces a deep trill. Those of *Nectarinia* are bursts of wheezy splutterings, whistles and twitters, with some trills and squeaks. The calls of the Golden-winged Sunbird, in the monotypic genus *Drepanorhynchus*, include a sharp "jwee" and rapid bursts of "cha-cha-cha-cha", and its song is a twittering and chattering mixed with high-pitched "chi-chi-chi" sounds.

Species of *Cinnyris* include some of the best songsters among the sunbirds. For instance, the song of the Southern Double-collared Sunbird starts and finishes with up to twelve hissing "ssssweee" notes or series of "siz, siz, siz", sandwiching a melodic warble of rising and falling "tsee" notes and sequences of rising "weeta witta witta-weeta, witta witta, witta witta wit". Males may sing to one another from perches for 15 minutes or more, sometimes exposing their pectoral tufts as they do so. This is one of the species in which the females, as well as the males, sing. Similarly, the song of the Black-bellied Sunbird begins with up to 20 "tsk", "chip" or "che" notes at rates of six per second, followed by a warble of ascending and descending "tsi" notes speeding up into a final flourish. The sequence is repeated again and again between pauses of up to 12 seconds, in songs lasting for 3 minutes or more. Other members of the genus, such as the Common Purple-banded and Violet-breasted Sunbirds, include more trills in their repertoires. The best-studied sunbird songs are those of the Splendid Sunbird, competing males of which at any one place may sing the same dialect to each other, while at dialect boundaries different dialects are sung at spots as little as 40 m apart. Such variation may be related to habitat patchiness and differences between open habitats and closed habitats in the distances over which vocalizations carry.

The most versatile of the known mimics among the sunbirds is another *Cinnyris* species, the White-breasted Sunbird. This imitates the Common Bulbul (*Pycnonotus barbatus*), Chestnut-vented Warbler (*Sylvia subcaerulea*), Neddicky (*Cisticola fulvicapilla*), Rattling Cisticola (*Cisticola chiniana*), Black-chested Prinia (*Prinia flavicans*), Bronze Mannikin (*Lonchura cucullata*) and Streaky-headed Seedeater (*Serinus gularis*), and perhaps a number of other species. Other mimics include another *Cinnyris* species, namely the Palestine Sunbird, and one species

As nectar-feeders, sunbirds play an important part in plant reproductive processes. In South Africa, for example, some 2% of all flowering plants are pollinated by sunbirds, which is a particularly impressive feat given the country's remarkable plant diversity. As sunbirds insert the bill into the corolla to reach the nectar within, the forehead, lores or bill base touches the anthers and becomes dusted with pollen. When the bird moves to another flowering plant of the same species, it deposits the pollen grains, which contain the male gametes, on the recipient plant's stigma, which leads to the ovules that house the female gametes in the ovary. As this male **White-breasted Sunbird** demonstrates, the build-up of pollen can be quite substantial, powdering a large area of the head.

[*Cinnyris talatala*, Kruger National Park, South Africa. Photos: David Stowe]

in each of the genera *Cyanomitra* and *Chalcomitra*, respectively the Green-headed Sunbird and the Socotra Sunbird.

Calls given by *Aethopyga* species, the final sunbird genus, tend to be high-pitched, metallic "tink" notes or weak "seep" notes, the songs being drawn-out trills. The trilling song of the Elegant Sunbird has been likened to the sound produced by certain insects.

Spiderhunters have simple calls consisting of metallic "chip" or similar short notes. Their songs are repetitions of such notes or, as in the case of the Little Spiderhunter, incessant squeaky whistles. The Naked-faced Spiderhunter utters a high-pitched insect-like "see", a low croaking "crrr", and a variety of rising and falling fast trills. Typically, spiderhunters' songs are monotonous more than melodious.

Food and Feeding

Probably all members of the family eat both animal and plant material. The genus *Deleornis* is mostly insectivorous, although one of its two species, the Grey-headed Sunbird, takes small fruits. Likewise, three *Anthreptes* species, the Mouse-brown, Plain-backed and Western Violet-backed Sunbirds, and one in *Anthodiaeta*, the Collared Sunbird, are to a large extent insectivorous. As the English vernacular name implies, sunbirds like sunny conditions, and a preference for feeding in sunlit places has been shown for the Palestine Sunbird.

Known foodplants of the Nectariniidae include more than 450 species of flowering plant of at least 345 genera, spread across 100 families. Of these, more than 400 species in at least 320 genera of 93 families are known to be exploited in Africa and more than 100 species in over 70 genera across 39 families in Asia. At least seven genera of Acanthaceae, six in Africa and two in Asia, are utilized, with up to three sunbird species recorded per genus. Six genera of Apocyanaceae are known foodplants, eight sunbird species utilizing the African genus *Thevetia*. Seven genera of the African family Asclepiadaceae are

recorded as being used, with up to six sunbird species per genus. Eleven African species of sunbird are known to feed upon at least three species of the balsam *Impatiens* (Balsaminaceae). Eleven genera of the plant family Bignoniaceae are recorded as food sources in Africa, with two of these genera also exploited in Asia, the most utilized being *Jacaranda* and *Kigelia*, visited each by eleven species of sunbird, *Spathodea*, visited by twelve species, and *Tecoma*, attracting as many as 27 nectariniid species. Up to nine species in each of the four genera of Bombaceae are recorded as food sources in Africa and Asia. The pawpaw or papaya plant (*Carica papaya*), in the family Caricaceae, is a known food source for twelve African and two Asian sunbirds. Over 13 species of sunbird utilize more than five species of *Lobelia* in the African family Campanulaceae, nine African sunbirds are known to utilize at least three species of *Combretum* (Combretaceae), and, in the same continent, nine genera of the Compositae are each a source of food for up to five species of sunbird. At least 66 species of *Erica* (Ericaceae) provide food materials for seven species of sunbird. Twelve genera in the Euphorbiaceae are utilized, most importantly: *Euphorbia*, used by eight nectariniids; *Macaranga*, visited by eleven; and *Manihot*, exploited by ten species. In Africa, two genera of the Guttiferae, *Hypericum* and *Symphonia*, are food sources for seven and 13 species, respectively, and up to five sunbird species are recorded for five African genera of the Iridaceae. At least six species of *Leonotis* are used by 28 sunbird species in Africa and one in Asia, and *Salvia*, another member of the Lamiaceae, provides food for ten African nectariniids.

Plants of the family Leguminosae are extremely important food sources for sunbirds. Well over 60 plant species in more than 42 genera are recorded as being used by members of this avian family, with nine genera frequented by eight or more species of sunbird. The five or more species of *Erythrina* recorded provide food to 34 African and nine Asian sunbirds, and the numerous species of *Acacia* are used by 20 species in Africa and nine in Asia. Other leguminous genera popular with sunbirds are *Acrocarpus*, *Bauhinia*, *Caesalpinia*, *Delonix*, *Schotia*, *Crotalaria*

and *Albizia*; indeed, 14 species of sunbird have been recorded as visitors to the last-mentioned genus in Africa.

Nine genera of the plant family Liliaceae are known food sources in Africa, most prominently *Aloe*, with more than eleven species frequented by 26 species of sunbird, and at least four species of *Kniphofia* used by 15 species of sunbird. The mistletoe family Loranthaceae, including *Viscum*, which is sometimes separated as the family Viscaceae, is a very important food resource for sunbirds. Particularly favoured genera are *Agelanthus*, *Englerina*, *Dendrophthoe*, *Tapinanthus* and *Phragmanthera*. Some sunbirds, such as the Variable Sunbird, are known to open closed flowers of *Tapinanthus* in order to reach the nectar. The genera of mistletoes utilized by 45 sunbird species, 36 African and nine Asian, have not been identified.

Seven genera of the Malvaceae are recorded as used by the Nectariniidae, mostly in Africa, with 28 species of sunbirds known to utilize at least three species of *Hibiscus*. Three genera of the Moraceae are documented as food sources, most prominent among them being the fig genus *Ficus*, recorded for ten species of sunbird. Three genera of the family Musaceae are exploited, including plantains and bananas (*Musa*), by 28 species, and *Strelitzia*, by eight species. Five genera of the Myrtaceae are noted as food sources for sunbirds, of which *Callistemon* is used by ten species, *Syzygium* by 15, and the numerous species of *Eucalyptus* by eleven species. Seven sunbirds in Africa use members of the genus *Fuchsia* (Onagraceae) for feeding. At least eight species of palm (Arecaceae), in seven genera, are utilized. The coconut palm (*Cocos*), with six African and four Asian species of sunbird as clients, is the most popular. In Africa, the family Proteaceae is important, with nine sunbird species recorded for the genus *Faurea*, twelve for *Grevillea*, and 15 nectariniids for over twelve species of *Protea*. Five genera of the Rosaceae are utilized, particularly *Prunus*, which is used by nine sunbird species. Over 24 genera of the Rubiaceae, each attracting up to five sunbird species, are recorded as food sources, principally in Africa. Thirteen African species of sunbird are recorded as feeding on *Halleria*, and at least five other genera in the family Scrophulariaceae are

used, as are eight African genera of the Solanaceae. More than nine genera of the Verbenaceae are known food sources, prominent among them being *Lantana*, recorded for ten species of sunbird. The gingers (Zingiberaceae), with more than five genera involved, are particularly important in Asia.

Of the non-flowering plants, the gymnosperm *Juniperus*, the juniper, is known to be utilized for food by one species in Africa. The lichen *Usnea* attracts three African species of sunbird, but these probably exploit it as a source of invertebrate prey or nest-building material.

Nectar is the most important plant product in the diet of sunbirds, being recorded for 93 species, with a further 21 species suspected of nectarivory. When more information becomes available, it will quite possibly be found that all of these species feed to some extent on nectar. A perceived problem of nectarivory is the ingestion of large amounts of water as part of dilute nectar. Experimental work on the Palestine Sunbird revealed that, with increased water ingestion, there was decreased water absorption in the intestinal tract, allowing the birds to take in large amounts of watery nectar or sugar solutions without an increase in glomerular filtration rate in the kidneys, as the rate of filtration is not sensitive to water-loading. The entire glucose filtered load was recovered by the kidneys, and water reabsorption by the kidneys decreased with increased water intake. This contrasts with the circumstances among the hummingbirds, which produce extremely dilute urine. In experimental studies of the Southern Double-collared Sunbird, it was found that this species can digest and absorb the sugars sucrose, glucose and fructose, but that xylose is excreted. Another study on the Palestine Sunbird showed that, as with hummingbirds and honeyeaters, this nectariniid has rather low nitrogen requirements and loses one third of the allometrically predicted value of nitrogen per day, attributable to its low-protein and high-sugar diet. The Southern Double-collared Sunbird manages to obtain its nitrogen requirements from pollen alone.

Sunbirds extract nectar by sucking, as do the sugarbirds, whereas hummingbirds, in contrast, lick nectar. As the sunbird tongue is extruded and retracted, it pushes against the upper man-

Short-billed sunbirds are at a disadvantage compared to long-billed species when seeking nectar from a flower with long corollas. But many such nectariniids circumvent this potential problem by piercing the corolla at its base and then extracting the nectar. This practice is known as nectar-robbing, as the bird gains the benefit of the nectar without being dusted with pollen from the anthers, thereby avoiding contributing to the plant's pollination process. Accordingly, the species that adopt this practice, such as the **Fork-tailed Sunbird**, are termed "nectar-thieves". Some 18 species in six sunbird genera, plus the spiderhunters (Arachnothera), are known nectar-thieves. Plant genera susceptible to nectar-robbing include *Hibiscus* and *Gardenia*.

Although nectariniids are best known for feeding on nectar, all species are thought likely also to consume invertebrates. Nectariniids have been recorded preying on a fair variety of insects, the commonest targets being bugs (Hemiptera), aphids (Aphidoidea), leafhoppers (Homoptera), termites (Isoptera), ants (Formicidae) and beetles (Coleoptera). This male **Palestine Sunbird** is waiting with intent, poised for the best moment to grab the tiny caterpillar crawling beneath it. Sunbirds prefer the larvae of Lepidoptera to the adults.

[*Cinnyris osea osea*, Tawi Atayr, Dhofar, Oman. Photo: Hanne & Jens Eriksen]

dible. Air is expelled from the large cavity in the fleshy part of the tongue as it is pushed forwards and upwards against the palate. The cavity is opened when the muscles pull downwards and backwards as the tongue is retracted. A slight vacuum is created, causing nectar to be drawn up the tongue into the posterior cavity. When the tongue is pushed forwards again, the nectar is forced over the back edge of the tongue and the tubercles, passing along the two grooves in the palate. As the groove in the tongue extends over its entire length, a continuous stream of nectar is pumped through the bill. There is no crop, and the oesophagus is non-distensible, so nectar passes directly in to the proventriculus

and on to the ventriculus (see Morphological Aspects). Thus, nectar cannot be stored, and sunbirds must feed frequently. In contrast, the relatively large crop of the hummingbirds allows for the storing of nectar. In most species of sunbird, however, the proventriculus is rather broader than the oesophagus and has thicker muscular walls (see Morphological Aspects), perhaps an indication of the greater importance of arthropods over nectar in the diet. The amount of sucrose in nectar varies, even within one species of plant. As examples, the nectar of *Banksia marginata*, a member of the Proteaceae, contains an average of 22% sucrose, but the content ranges from 3% to 55%, equivalent to 0.09–2.11 molar (gram molecular mass/dm³ of solution), and in the lamiaceous *Leonotis leonurus* it varies from 16% to 25%, the average being 23%.

In laboratory conditions, and with artificial nectar-feeders used as flower substitutes, Malachite Sunbirds drink larger volumes if the sugar solution is more dilute. In addition, the rate of sugar-solution uptake by Bronze Sunbirds is less if the feeders have longer "corollas", as the amount obtained per "suck" is lower. In captivity, the White-breasted Sunbird, in order to receive a constant intake of sucrose, was found to adjust the intake volume of solution when the concentration varied from 0.25 to 2.5 molar; at concentrations of 0.07–0.1 molar, however, the birds lost mass, as they were unable to ingest sufficient for their energy requirements. Free-water consumption varies, increasing as sucrose concentration in the diet increases, and effectively diluting the most concentrated solutions to an average of 1.05 molar, which is presumably the preferred concentration.

At Zaria, in Nigeria, nectar from 37 species in 34 plant genera was taken by seven species of sunbird. The two principal sunbird species involved, the Pygmy and Scarlet-chested Sunbirds, exploited mainly different species of plant, the shorter-billed Pygmy Sunbird foraging at smaller flowers than those utilized by the longer-billed Scarlet-chested, although there was some overlap, as the Pygmy Sunbird could "nectar-rob" the larger flowers. It was also noted that high night-time temperatures and low humidity could cause the nectar to become "toffee-like", so that it was then available to birds only if they ingested parts of the flowers as well.

Fruits are less important for nectariniids, having been recorded as food for 33 species of sunbird, and seeds have been documented as taken by 21 species. Only ten members of the family

More than 70 species of nectariniid feed on spiders (Araneae), and this prey type is enshrined in the English and scientific names of the spiderhunter genus, *Arachnothera*.

This male **Olive-bellied Sunbird** has gleaned a white spider from the outer foliage of a tree. Leaf-gleaning is a commonly used foraging technique in this family. Sunbirds often defend feeding territories to ensure that they and their kin have access to adequate food resources. Some Olive-bellied Sunbirds fit into this category, defending territories against other sunbirds and even against sphingid moths (*Sphingidae*).

[*Cinnyris chloropygius orphogaster*, Katwe Crater Lake, Uganda. Photo: A. P. Leventis]

are known to feed on pollen, and one more is suspected of so doing, but many more will unwittingly carry pollen on the head and, to some extent, on other parts, such as the feet, and hence act as pollinators. Other vegetable items, such as leaves and flower parts, are of minor importance.

Plant exudates from fig-wasps (*Elisabethiella*) are recorded as a food item for three African species, including the Greater Double-collared Sunbird. The Miombo Double-collared, White-breasted and Common Purple-banded Sunbirds feed on an exudate from beans of the *Cassia singuena* tree that have previously been opened by Common Bulbuls or Black-collared Barbets (*Lybius torquatus*). In this situation, the Miombo Double-collared Sunbird is dominant over the two other sunbirds. The Amethyst Sunbird is known to take oozing coconut sap. Latex balls, particularly from the euphorbiaceous genus *Manihot*, have been found in the stomachs of ten species of sunbird in Africa. In one specimen of the Splendid Sunbird the ball almost filled the stomach, and in a specimen of the Copper Sunbird such a ball was found at least four months after *Manihot glaziovii* had ceased flowering. These observations suggest that the latex is indigestible, and that it was probably accidentally ingested when the bird pierced vascular tissues of the plant while nectar-robbing. Such balls, especially if of substantial size, could be only detrimental to the bird. In Asia, the Purple Sunbird is attracted to toddy palms (*Caryota urens*) when these are being tapped.

Vertebrate prey has been documented for only one member of the family, the Malachite Sunbird, which has been recorded as taking small lizards in Africa. In contrast, it is very likely that all sunbird and spiderhunter species take invertebrate prey, particularly arthropods. Twelve orders of insect are represented in the

nectariniid diet, six of these being prominent. Termites (Isoptera) are known to be eaten by 16 species, and bugs (Hemiptera), particularly cicadas (Cicadoidea), aphids (Aphidoidea) and leafhoppers (Homoptera), are taken by 27 species. Small beetles (Coleoptera) are known prey items of 31 sunbird species, although only one of these is known to take beetle larvae, probably because the majority of such larvae are concealed and would have to be prised from wood or other plant material, or dug from soil. Members of the insect order Hymenoptera are an important food resource, this being particularly so of ants (Formicidae), which are taken by 27 species of sunbird. A variety of true flies (Diptera), including gnats (Culicidae), midges (Chironomidae) and hoverflies (Syrphidae), is eaten by this family. Although a number of nectariniids take moths and butterflies (Lepidoptera), it is the larvae of these insects, the caterpillars, that are particularly favoured, being consumed by 35 species of sunbird. A further 35–43 sunbird species are recorded as taking insects, but with no details of the orders to which the prey belong.

Spiders (Araneae) are popular prey, forming part of the diet for more than 70 species of sunbird and spiderhunter. Other invertebrates taken by small numbers of species include mites (Acari), snails (Gastropoda) and nematodes (Nematoda). Odd items are occasionally noted, such as sand in the stomach of Uluguru Violet-backed Sunbirds, and small shells, quartz, sand and grit in the stomach of Olive-bellied Sunbirds.

Sunbirds pollinate many plants, and it has been calculated that up to 2% of South African flowering plants are pollinated by them. Although some species have preferences for particular plants, there seems to be little evidence of co-evolution of bill length and corolla-tube length that would lead to a particular spe-

Like other birds, nectariniids need to drink if their diet does not provide sufficient water to balance losses through excretion or pulmonary evaporation. This male **Mariqua Sunbird** is drinking by reaching down into the water below, and sucking it upwards into its bill. This technique requires a degree of balance not needed in the drinking technique most commonly deployed by birds, that of taking a sip then tilting the head backwards so that the water trickles down the throat by gravity. Water may be a scarce resource for populations of the Mariqua Sunbird that inhabit dry acacia (*Acacia*) savanna, but a more abundant one for other populations in riverine and swamp-fringing forests. Sunbirds also ingest water when feeding on nectar. Indeed, it is thought that nectarivory may have the undesirable side-effect of taking in too much water in the form of dilute nectar. The Mariqua Sunbird has a varied diet, and consumes nectar, spiders (Araneae) and insects as varied as flies (Diptera) and termites (Isoptera), which it takes by leaf-gleaning, hovering or hawking.

Like all its congeners, the **Grey-breasted Spiderhunter** has a mixed diet. Inserting its long bill into the corollas of flowering plants, it sucks up nectar. It also feeds on spiders (Araneae) and on insects, such as crickets (Orthoptera) and ants (Formicidae). This individual appears to be searching for arthropods skulking amidst the petals of the inflorescence on which it is perched. Spiderhunters are generally less gregarious than sunbirds, and the Grey-breasted Spiderhunter tends to forage alone or in pairs. It exploits food sources at all levels of the forest, and is often encountered in the lower and middle storeys.

cies of sunbird being closely adapted for the pollination of a certain species of plant. At flowers with deep corollas, longer-billed sunbirds are obviously at an advantage over shorter-billed ones, but the latter may surmount this problem by nectar-robbing, whereby they pierce the base of the corolla and extract the nectar without any pollination occurring. Eighteen species from the genera *Anthreptes*, *Anthodiaeta*, *Cyanomitra*, *Chalcomitra*, *Leptocoma* and *Cinnyris*, and the spiderhunters in *Arachnothera*, are known to be nectar-thieves. The victims, usually large or long flowers such as those of *Hibiscus*, robbed by Purple-rumped, Olive-bellied, Miombo Double-collared, Southern Double-collared, Red-chested, Palestine and Seychelles Sunbirds, and those of *Gardenia*, robbed by Eastern Olive, Southern Double-collared and Variable Sunbirds, have the corolla pierced at the base by the sunbird's bill; the bird thus withdraws the nectar without necessarily touching the anthers and being dusted with pollen. The Souimanga Sunbird pierces unopened flower buds to reach the nectar. Other nectar-thieves include the Brown-throated, Stuhlmann's Double-collared, Montane Double-collared and Loten's Sunbirds. One suggestion of co-evolution in Africa is that between the Golden-winged Sunbird and the lion's claw (*Crotalaria agatiflora*), the bird frequently having a coating of this plant's pollen on the crown and, in particular, in the medial groove between the feathers of the crown. Another example of co-evolution between plants and sunbirds is the specialized bird perch, in the form of a vertical protrusion resembling the tail of a rat, of the appropriately named rat's-tail plant (*Babiana ringens*). The Malachite Sunbird perches on this in order to reach down to probe the inflorescences of this South African Cape endemic member of the Iridaceae, thereby picking up pollen on its breast for later transfer to other plants of the species.

The role of this family in pollinating flowers is important, and sometimes the forehead of the sunbird is heavily encrusted with pollen. When feeding on nectar, many sunbirds will probe into the corolla from the top, and may thus effect pollination, but there is not much evidence of specific relationships between particular sunbirds and plants, although the Brown-throated Sunbird is a known pollinator of the spice plant *Nicolaia elatior*. The Purple Sunbird is an important pollinator of various mistletoes such as *Loranthus longiflorus*, which it does by gentle squeezing of the bud tip to open it, and then it probes for nectar. The Purple-

rumped Sunbird inserts its bill into the deep slits of the corolla of *L. longiflorus*, which triggers the separation of the fused elements, thereby exposing the pollen. The Orange-breasted Sunbird is recorded as feeding on 66 species of *Erica*, the florets of which it probes while clinging to the stems. It is suggested that it may have co-evolved with *Erica*, because the ornithophilous (bird-pollinated) species are thicker-stemmed than both the entomophilous (insect-pollinated) and anemophilous (wind-pollinated) species, and the stem girth of the ornithophilous species is greater

Spiderhunters have longer bills than sunbirds and deploy them to good effect when foraging. The longer the spiderhunter's bill, the deeper it can penetrate into the corollas of flowering plants to access the nectar lying within. The **Streaked Spiderhunter** is particularly fond of the nectar of the inflorescences of banana (*Musa*) trees. Like most of its congeners, this species usually forages singly or in pairs, but also joins mixed-species flocks. It inhabits various types of forest, displaying a preference for feeding in the canopy but also willing to descend to lower levels. As well as nectar, the Streaked Spiderhunter forages for insects and spiders (Araneae), even extracting the latter from their webs, a feat that requires considerable dexterity.

[*Arachnothera magna pagodarum*,
Kaeng Krachan NP,
Phetchburi, Thailand.
Photo: Kaniit Khanikul]

For most of its length, the long tongue of the spider-hunters forms a perfect tube, but towards the tip it splits off into two incomplete tubes with fimbriated inner edges. While distinctive in its own way, this structure does not differ greatly from that found in most of the sunbird genera, and this sort of tongue serves as a very good tool for extracting nectar. Effectively, as the tongue is moved in and out, it is pushed against the upper mandible to create a vacuum, which sucks the nectar up off the flower. The

Grey-breasted Spiderhunter feeds on a variety of arthropods as well as nectar. It forages singly or in pairs in all storeys of the forest. It is the lowland counterpart of the **Streaky-breasted Spiderhunter** (*Arachnothera affinis*), and these two may form a superspecies.

than would be required merely for flower support or for nectar production.

Pollinia, packets of pollen with mechanical clips for attachment, are produced by orchids and milkweeds (Asclepiadaceae) and are vehicles for pollination by specific insects. Pollinia of the milkweed *Microloma sagittatum* have been found on the tongue of the Southern Double-collared Sunbird, and the pollinia of an unidentified milkweed or orchid were discovered on the tongue of an Orange-breasted Sunbird. Both of these occurrences

Most sunbirds are territorial during the breeding season. Males defend their territories by singing from exposed locations. Such positions serve a dual purpose: they enable the territory-holder to survey his domain for intruders; and permit any potential rivals or mates to see that the territory already has an owner. Should a sunbird stray into the territory of a conspecific, it is likely to be the recipient of aggressive behaviour from the incumbent. Territorial male **Collared Sunbirds** chase each other while clicking their wings.

were in South Africa. The first case was attributed to the presence of a specialized groove on the tongue (see Morphological Aspects), and the pollinia were detached mechanically on arrival at the next plant; the second example, however, appeared to be accidental, as the tongue was being prevented from curling properly into a tube by the presence of the pollinia, which almost certainly had a detrimental effect on the sunbird's feeding. The orchids *Disa chrysostachya* and *Disa satyriopsis*, however, are also pollinated by sunbirds. In South Africa, the first of those two is pollinated by Malachite Sunbirds, and probably also by Amethyst, White-breasted and Greater Double-collared Sunbirds; and in Malawi, *Disa satyriopsis* is visited, and probably pollinated, by Malachite Sunbirds and Montane Double-Collared Sunbirds. Pollinaria of these orchids become attached firmly to the bird's toes when it perches on the tall narrow inflorescences in order to probe flowers on them. Sunbirds perching on flowers of *Strelitzia* may also pollinate with their feet.

In addition to breeding territories (see Breeding), many sunbirds defend feeding territories. The tree-like plant *Balthasaria schliebenii*, a member of the Theaceae family, is defended by Blue-headed Sunbirds in Africa. *Leonotis leonurus*, the wild dagga, is defended by the Eastern Olive Sunbird against conspecifics and other sunbirds, whereas, in places where this plant grows in abundance, up to 1350 Malachite Sunbirds can be found in an area of just 1 ha; the Bronze Sunbird often has members of the plant genus *Leonotis* within its breeding territory. The Western Olive Sunbird defends feeding territories around both *Symphonia globulifera* and *Syzygium congolense* trees, and both sexes of the Purple-breasted Sunbird hold territories against conspecifics around the former, although up to twelve individuals of this species may feed together. Mistletoes are associated with a number of sunbird species. The Rufous-winged Sunbird holds a feeding territory around these plants, and may defend several clumps of mistletoe at once against other species of sunbird, and the Kenya Violet-backed Sunbird is said to depend on mistletoes, dominating Black-bellied Sunbirds at the flowers. Beautiful, Gould's and Brown-throated Sunbirds, too, feed on mistletoes, the last being known to nectar-rob them. The Purple Sunbird is usually found close to mistletoes and is an important pollinator, and the Purple-rumped Sunbird is also known to propagate them.

The division of nectariniid parental responsibilities is such that females take sole charge of nest construction. This female **Purple Sunbird** has collected some fibres, possibly animal hair, which she will use to build the basic structure of her nest. From start to finish, nest preparation may take as few as five days or as many as 15. In addition to fibres, the female Purple Sunbird collects soft grass, leaves and spider webs as core building materials. When applying the finishing touches, the female seeks out bark, caterpillar frass and other such objects to provide decoration. Finally, she lines the nest with seed-down, to provide eggs and nestlings with comfort and insulation.

[*Cinnyris asiaticus brevirostris*, Muscat, Oman. Photo: Hanne & Jens Eriksen]

Flowering rhododendrons (*Rhododendron*) in the Himalayan ranges attract Gould's and Fire-tailed Sunbirds, and perhaps other congeners. In equatorial regions of Africa the Bronze Sunbird is closely associated with *Erythrina abyssinica*. The Souimanga Sunbird guards aloe flowers and is aggressive towards the Long-billed Green Sunbird, but only the female of the former is regarded as disputing flowers of *Bakerella* species. The Green-headed Sunbird is known to gather in groups of up to 30 males in *Xylopia aethiopica* trees, each male defending an area of 2–4 m in diameter. Experimental work has shown that the Eastern Olive Sunbird expends 5.4 kJ of energy per day in defending clumps of *Leonotis leonurus* against both intraspecific and interspecific competitors, and that it gains 57 kJ per day from the nectar. Male Crimson-backed Sunbirds defend flowering trees against conspecifics and flowerpeckers.

Protea is important to both Orange-breasted and Bronze Sunbirds, and the latter has increased in the highlands of Zimbabwe following the commercial growing of this plant. The Red-tufted, Malachite and Tacaze Sunbirds defend territories that contain *Protea* inflorescences. It has been calculated that the Golden-winged Sunbird, which defends extensive patches of *Leonotis nepetifolia*, can obtain 76% of its energy requirements from such territories. Male Olive-bellied Sunbirds, which prefer pink *Hibiscus rosa-sinensis* flowers to red ones, probably because the latter are nectar-depleted by butterflies, sometimes hold feeding territories which they defend against other sunbirds and against sphingid moths. So far as the defending of feeding territories is concerned, the Tiny Sunbird is erratic, its behaviour being dependent on flower availability. The Mariqua Sunbird defends such territories throughout the year, and there is some evidence of territoriality among Superb Sunbirds. Miombo Double-collared Sunbirds defend feeding territories against each other. In Madagascar, male Long-billed Green Sunbirds are territorial at flowering trees.

Less seems to be known about the territorial behaviour of foraging spiderhunters. An apparent pair of Yellow-eared Spiderhunters has been noted as defending a flowering patch of canopy lianes against other spiderhunters.

Wild gingers attract Thick-billed, Grey-breasted and Streaked Spiderhunters, whereas banana flowers are favoured by the Superb Sunbird in Africa and, in Asia, by the Little, Thick-billed,

Yellow-eared, Naked-faced, Streaky-breasted, Grey-breasted and Streaked Spiderhunters. Whitehead's Spiderhunter is known to frequent orchids (Orchidaceae). For well-studied nectariniid species the total number of foodplants can be quite large. The Souimanga Sunbird, for example, is associated with at least 26 species.

Thirty-eight species of sunbird and two species of spiderhunter have been observed to hover while foraging. Among the sunbirds, this habit is recorded for members of the genera *Chalcoparia*,

As with other sunbirds, it is the female **Olive-backed Sunbird** that takes control of building the nest in which to raise her brood. This species' nest is a hanging oval purse that is normally 30–60 cm in length, the variation usually depending on the length of the dangling "beard" that can be seen in this photograph. Principal building materials include grass, moss, cotton, lichen, vegetable fibres and spider webs. This female is putting the finishing touches to the nest, returning with a feather to provide a snug, soft inner lining. The nest is normally suspended 1 m or so above ground, hanging from a plant or man-made object.

[*Cinnyris jugularis ornatus*, Mandai Orchid Garden, Singapore. Photo: Jimmy Chew]

In a family where nest-construction is almost entirely the prerogative of the female, the **Purple-rumped Sunbird** stands out as an exception. In this species, the male (seen here) assists the female with collecting suitable nest material and weaving it together. The nest is not dissimilar in shape to that of other sunbirds, being an oval or pear-shaped purse, often with a porch or hood above the entrance hole. The exact building materials of course depend on what is available locally in the Purple-rumped Sunbird's habitat. Grass and fibres form the basis of most nests, which are subsequently lined with soft plant down. External decoration is provided by materials such as lichen, bark, moss and caterpillar frass. The nest is usually suspended from the tip of a branch, some 2–15 m above the ground, but some nests hang from artificial constructs such as buildings and even, in one recorded instance, a light bulb. Nectariniids nesting outside the tropics tend to time their breeding to coincide with the wet season. Within the tropics, particularly near the Equator, sunbirds are more likely to breed in any month. Resident in India, Bangladesh and Sri Lanka, the Purple-rumped Sunbird has been recorded egg-laying in all months, with breeding peaks varying according to region and the exact timing of the monsoon.

[*Leptocoma zeylonica flaviventris*,

Eriksen]

Anthreptes, *Anthodiaeta*, *Dreptes*, *Cyanomitra*, *Chalcomitra*, *Leptocoma*, *Nectarinia* and *Cinnyris*. Many sunbirds hover at flowers while taking nectar, and some use hovering as a method of obtaining insects, as with the hover-gleaning practised by the Olive-backed, Humblot's and Purple-rumped Sunbirds. Others, such as the Ruby-cheeked and Bronze Sunbirds and the Little Spiderhunter, hover at spider webs, when spiders may also be the intended prey. Hovering at ant nests has also been recorded, and the Little Green Sunbird hovers while probing figs.

Hawking and sallying for insects are techniques noted for 38 species from the sunbird genera *Anthreptes*, *Anthodiaeta*,

Anabathmis, *Anthobaphes*, *Cyanomitra*, *Chalcomitra*, *Nectarinia*, *Drepanorhynchus*, *Cinnyris* and *Aethopyga*. Reichenbach's Sunbird is one such example. This species sits for long periods on the same perch, to which it returns repeatedly after hawking for insects.

Leaf-gleaning, sometimes carried out during hovering, is a common and widespread method of gathering insects and spiders. It has been recorded for all nectariniid genera except *Hypogramma*, *Anthobaphes* and *Arachnothera*, and it is probable that members of these genera also use it.

Less usual methods of feeding have been recorded. The Orange-breasted Sunbird has been observed to stand on the ground and probe in grass in a manner reminiscent of a wader or shorebird (Charadriiformes). The Kenya Violet-backed, Sao Tome, Eastern Olive, Scarlet-chested, Splendid and Seychelles Sunbirds and the Yellow-eared Spiderhunter are known to probe bark. This behaviour, believed to be undertaken in search of insects, has been likened to that of a tree creeper (Certhiidae), for example in the Sao Tome Sunbird, and the Splendid Sunbird has been recorded as probing for oozing sap on the trunks of oil palms. The Red-tufted Sunbird runs up the inflorescences of giant lobelias (*Lobelia teleki* and *L. keniensis*), taking not only nectar but also small insects. When feeding at *Lobelia keniensis*, this species seeks out chironomid larvae in water pools formed in the rosettes of this plant, and also seizes bibionid flies. Both of these food items are important in its diet, the latter recorded as constituting up to 90% of the stomach contents of Red-tufted Sunbirds in Kenya.

Some members of the family often visit houses and other buildings for the purpose of foraging, tending to feed particularly on insects at window panes or on spiders taken from their webs. Remarkably, an individual Bronze Sunbird was once observed taking spiders from a web within an occupied school classroom.

There are other interesting details in the foraging behaviour of the Nectariniidae. For example, Reichenbach's Sunbird probes the corollas of the mistletoe *Globimetula braunii*, the flower petals of which have specialized edges; these respond to probing by causing the corolla tube to split open and the stamens to coil inwards explosively, thus enhancing pollination chances. The Orange-breasted Sunbird clings to the side of the flower of *Protea lepidocarpodendron* and probes, with its bill at right angles, into the bracts to reach the nectar. In fynbos, this species competes with the Cape Sugarbird (*Promerops cafer*) for the nectar of protea species. The Western Olive Sunbird competes at flowers of the yellow trumpetbush (*Tecoma stans*) with the honeybee (*Apis mellifera*), the insect attempting to deter the sunbird by flying at

Nectariniids often place their nests in rather exposed positions, such as at the tip of a branch a few metres above ground level. Such prominent sites risk attracting the attention of predators and brood parasites such as cuckoos (Cuculidae). Nest disguise is thus an important consideration, so the outer layer of the nest is often designed to meet such requirements. Dead leaves make up much of the construction material for the nest of the **Western Violet-backed Sunbird** and provide fairly effective concealment. The remainder of the nest comprises bark, grass and spider webs.

[*Anthreptes longuemarei* angolensis, Mutinondo Wilderness Area, Zambia. Photo: Warwick Tarboton]

Whereas sunbird nests are frequently located in highly visible locations, those of spiderhunters tend to be more concealed. This **Long billed Spiderhunter** has placed its nest on the underside of a large banana (*Musa*) leaf. The bird uses spider webs to attach the nest to the leaf or, alternatively, sews together the leaf edges to form a tube. The nest tends to be bottle-shaped with a cup at one end and can be more than 40 cm long; a wide entrance hole leads via a lengthy tunnel to the nest chamber. Such concealment has advantages, but one of the costs is that if a parent wants to alight alongside its nest, it is obliged to do so upside-down.

[*Arachnothera robusta* robusta, Taman Negara, Peninsular Malaysia. Photo: Ong Kiem Sian]

Sunbird nests commonly have a porch over the entrance, offering shade from the sun and shelter from the rain, as in this nest of **Loten's Sunbird**.

This species' nest is a rather ragged, pendulous pouch that hangs from a twig or branch up to 3 m above the ground. Nests, as in this instance, are frequently surrounded by spider webs. The nest is constructed from plant matter such as lichens, leaves, grass, moss and rootlets; wool or plant down provides a suitably soft and warm lining for the eggs and, subsequently, nestlings. In India, Loten's Sunbird has been recorded breeding in all months of the year, but with a peak between March and May (January to May in Kerala). In Sri Lanka, it appears to vary its breeding season in accordance with location and climate. In the damp highlands, it breeds between August and December, whereas in the dry lowlands, the breeding season is from February to May. Average clutch size is 2–3 eggs, but, rather surprisingly for a fairly common species, nothing is known about the incubation or nestling periods, or even parental responsibilities.

[*Cinnyris lotenius lotenius*,
Sri Lanka .

its face. This nectariniid, incidentally, has been known to become fatally entangled in spider webs. In contrast, a pair of Amethyst Sunbirds has been observed to take over an active spider nest for its own use, the birds feeding on the numerous spiderlings crawling over the nest.

The Purple-rumped and Purple Sunbirds include grapes in their diets. They pierce these fruits and suck out the juices. In the Hyderabad area of peninsular India, their depredations, particularly on the peripheries of vineyards, are such that they are considered pests (see Relationship with Man).

Breeding

Outside equatorial regions, the majority of sunbird species breed during wet seasons, when there are sufficient insects available to feed their young. Some, however, nest in the dry season, and yet others breed throughout the year. One dry-season nester, the Pygmy Sunbird, migrates south to do so. In East Africa this species breeds from October to December, and in West Africa it lays eggs from December to April. The reasons why such species nest in dry periods are unclear, but they are probably linked with the flowering of favoured foodplants, such as *Bombax* species, *Ceiba pentandra* and *Erythrina senegalensis*, and the associated flush of insects that permits so many insectivorous migrants from the Palearctic to survive the harsh conditions (Moreau's Paradox). The Pygmy Sunbird breeds in the savanna, but some forest-dwelling species also nest in the dry season, as does the Buff-throated Sunbird in Nigeria.

Many bird species inhabiting equatorial zones may breed at any time of the year, examples among the Nectariniidae being the Purple-breasted Sunbird and the Golden-winged Sunbird.

Typical wet-season breeders include the Copper Sunbird and the Splendid Sunbird. Those species breeding in all months tend to have peaks of activity at some period during the year. For instance, although the Orange-breasted Sunbird may nest during any month, it does so more commonly during May to August. Such species can exploit the conditions and be double-brooded or even triple-brooded.

The majority of sunbirds are territorial in the breeding season. The extent of the area defended varies with species and habitat, singing males of the Palestine Sunbird occurring at densities of 6.4 per hectare but those of the Splendid Sunbird being spaced at 0.16 males per hectare. Territories are defended by males, which sing from vantage points such as treetops and demonstrate aggressive behaviour towards conspecific intruders. Males of the Scarlet-tufted Sunbird display aggressively to other males by uttering shrill calls, projecting the head and tail forwards, spreading the tail, drooping the wings, thereby exposing the pectoral tufts, and opening the bill to expose a red-orange mouth. The Purple-rumped Sunbird defends an area with a radius of up to 250 m, using a similar display. Territories of the Red-tufted Sunbird vary in size from 1700 m² to 3300 m² according to altitude and available resources. Interspecific encounters also occur among territorial sunbirds, the last-mentioned species chasing away Montane Double-collared Sunbirds. In this respect the Copper Sunbird is notorious, having been seen to drive out of its territory many different species, among them the African Masked Weaver (*Ploceus velatus*), the Village Weaver (*Ploceus cucullatus*), the House Sparrow (*Passer domesticus*), the Common Bulbul, the Scarlet-chested Sunbird, the Common Fiscal (*Lanius collaris*), the Kurrichane Thrush (*Turdus libonyanus*) and the Diederik Cuckoo (*Chrysococcyx caprius*). Defence is most intense during periods when eggs are being incubated.

For those species for which the information is available, the mating system is normally a monogamous one, involving simple pairs. Co-operative behaviour has been recorded for a few species, and it may prove to be commonplace. The Straight-billed Green Sunbird is suspected of being a co-operative breeder, as helpers have been seen to attend the young of this species. Helpers have been reported also among Seychelles and Violet-tailed Sunbirds, and co-operative feeding of the young by more than two adults has been noted for the Purple-rumped Sunbird. Extra-pair copulations have been witnessed in the case of the Purple-rumped Sunbird, the Palestine Sunbird and the Malachite Sunbird.

Copulation usually follows some elaborate displays by males. Those possessing pectoral tufts, such as the Malachite Sunbird, will expose these tufts while raising the tail and fluttering the wings. Courtship by the Plain-backed Sunbird involves the male in chasing a female until the latter perches; the male then lands above her, flicks his wings, exposes the pectoral tufts and sings while the female quivers her wings. In the case of the Collared Sunbird, courting males lean forwards and jump from side to side while flapping their wings and calling "chi-chi". A male may display simultaneously to more than one female. With the Nile Valley Sunbird, display-dances and display-flights are involved in courtship rituals. The Purple-rumped Sunbird copulates in trees, bushes or creepers. One pair was seen to mate three times within a four-hour period.

What appears to be lekking behaviour is known to be practised by Sao Tome Sunbirds, Blue-throated Brown Sunbirds, Eastern Olive Sunbirds and Western Olive Sunbirds. Blue-throated Brown Sunbirds gather in groups of normally 4–7 individuals, but up to 45 singing males have been observed together at the beginning of the rains in Gabon. In this case, the birds perched on dead branches or in fruiting or blooming *Xylopia* trees, where they hopped from branch to branch, and faced each other with the pectoral tufts exposed and the chest inflated; during this display they sang, holding the head thrown back, the bill wide open, the wings drooping, and the lowered tail spread. Female Blue-throated Brown Sunbirds were present, but merely as observers, and they did not take part in the displays or indulge in copulation.

Nest-building is a task delegated to the female. Nests of spiderhunters are distinctive in being quite unlike those of sunbirds. The Little Spiderhunter and the Streaked Spiderhunter

Unlike most nectariniids, the male **Malachite Sunbird** plays a role in nest construction—albeit not a particularly active one. The male simply accompanies his partner as she searches for suitable building material such as grass, fibres, twigs and rootlets for the basic form; lichen for external decoration; and feathers, down and wool for the lining. Nest construction usually takes 7–30 days, although a particularly diligent female may complete the task within just three days. The nest is a relatively neat oval, some having a porch, a straggling "beard", or both. Many sunbirds suspend the nest from a branch or twig, but the Malachite Sunbird often sites its nest within a bush, frequently above water. The male has a rather elaborate courtship display, during which he makes good use of his elongated central tail feathers.

[*Nectarinia famosa famosa*,
Hermanus, South Africa.
Photo: J. A. Bailey/Ardea]

This incubating female **Collared Sunbird** is likely to be sitting on anything up to four eggs. This species is unusual among the Nectariniidae in that the male sometimes helps with incubation duties.

Once the eggs have hatched, after 17–19 days, both parents provision the chicks for around two weeks, and the brooding female may receive food from the male. The female,

however, takes sole responsibility for building the nest in which to raise the brood. Construction may take as few as one-and-a-half days or as many as seven. The nest is pear-shaped, with a side entrance hole, porch and, sometimes, a dangling "beard" comprising dead leaves and spider webs.

This female has chosen to suspend her nest from a spiny Euphorbia. The spines may provide natural protection against mammalian predators, and certainly monkeys are known to predate Collared Sunbird nestlings.

This species ranges over most of sub-Saharan Africa. Such a wide distribution, covering varied topography and habitat, provides the backdrop for considerable taxonomic uncertainty.

Nine subspecies are currently recognized, but one or more further species actually may be involved.

[*Anthodiaeta collaris zuluensis*,
Mkuzi Game Reserve,
KwaZulu-Natal,
South Africa.
Photo: Alan Weaving/
Ardea]

Spiderhunter nests tend to be rather neat constructions. That of the **Spectacled Spiderhunter** is a compact, circular cup, sometimes with a spout, and is made from compacted plant fibre. In common with congeners, and in contrast to most sunbirds, the Spectacled Spiderhunter conceals its nest by attaching it to the underside of large leaves, for example those of palms or rubber. As this species normally forages in the middle or upper storeys, it is not surprising that it places its nest at least 5 m above ground—higher than most nectariniids. Like most spiderhunters for which data exist, the Spectacled Spiderhunter lays two eggs.

[*Arachnothera flavigaster*, Panti Forest, Peninsular Malaysia. Photo: Jimmy Chew]

construct a cup which they attach to the underside of a banana leaf or palm frond. The Yellow-eared Spiderhunter places its nest similarly, but the nest itself is an elongated tube attached to the leaf by sewing with cobweb, and that of the Long-billed Spiderhunter is bottle-shaped and made of grass stems. Most sunbird nests, in contrast, are purse-shaped or flask-shaped ovals woven from grass, and are suspended; all are enclosed. Some have a porch over the entrance, and a “beard” trailing below the nest is a frequent feature. Exceptions to this general pattern include the nests of the Orange-breasted Sunbird, which are placed in protea bushes, and those of the Pygmy Sunbird, which are usually attached to branches within the body of a thornbush such as acacia, *Bougainvillea*, *Balanites aegyptiaca* or *Dichrostachys cinerea*. Some sunbird nests, such as those of the Collared, Scarlet-chested and Mariqua Sunbirds, are sometimes protected by their placement, being built near nests of stinging wasps.

Some members of the family associate with human habitations, nesting on houses, on verandahs or even inside huts. The Palestine Sunbird has been found to nest in houses, and one pair chose to build its nest inside the trouser leg of a pair of shorts left hanging to dry. Other species found nest-building inside houses include the Mouse-coloured Sunbird, the Eastern Olive Sunbird and Hunter’s Sunbird. Nectariniids which often nest on or close to houses include the Copper Sunbird and the Miombo Double-collared Sunbird.

An unusual Purple Sunbird nest was discovered in 2005 in India. This was suspended from hanging wire in a corridor of the Department of Zoology at the University of Jodhpur, in Rajasthan. The exterior of the nest was constructed from spider webs, grass pieces, leaves and thin strips of polythene, the last applied solidly in a crisscross pattern. Once the sunbirds had completed the breeding attempt, successfully, the nest was dismantled, when it was found to consist of 60% spider webs, 20% white polythene strips and 15% grass leaves, the remaining 5% being made up of small pieces of paper and the down feathers of birds. The lining consisted of small strips of polythene, paper and down. Although it is not uncommon for birds of many species to make use of artificial materials for nest-building, the utilization of polythene by Purple Sunbirds does seem somewhat extraordinary.

Many sunbird nests are concealed by decorations consisting of a variety of materials, including dead leaves, lichen, mosses, insect frass and cobwebs. The most remarkable of such nests is

that of the Blue-throated Brown Sunbird, which may be up to 1 m in height and has the appearance of a tangle of dead vegetation. The nest itself is in the middle, and the whole structure built of stems, twigs, dead leaves, *Marasmius* fungus, spider webs, fibres and moss. The deep cup is lined with bark fibres and sometimes with mammal hairs, including those of gorilla (*Gorilla gorilla*), and the entrance is protected by a short porch made from bark. The nests of approximately 15% of sunbird species have apparently not yet been described.

Sunbird eggs are generally shaped like miniature hen’s eggs. Some, however, are elongated, as is so with the largest of the sunbirds, the Sao Tome Sunbird, the eggs of which are 21.5 mm long and 15 mm wide, and white, with small red spots. The eggs of spiderhunters are also large, with a maximum size of 22 ×

Female nectariniids tend to take most of the responsibility for feeding the offspring. However, males also play a role, particularly once the young have fledged. This male **Olive-backed Sunbird**—sexed by its iridescent throat and upper breast—is taking a spider (Araneae) to provision its growing offspring. In Australia, the Olive-backed Sunbird nests in all months, but with a peak in the drier period between October and March. The breeding season is more concentrated elsewhere in the species’ range.

[*Cinnyris jugularis frenatus*, Townsville, Queensland, Australia. Photo: Clifford & Dawn Frith]

With two growing nestlings to feed, this female **Malachite Sunbird** has plenty to keep her busy. Like other sunbirds, the female does most of the provisioning for the 2–3 week nestling period, sometimes assisted by the male. The labour is shared more evenly once the chicks have fledged. The fledglings gradually become independent, roosting in the nest for the first fortnight after leaving it. Once the fledglings have departed, their parents may be able to set about raising another family: the Malachite Sunbird is double- or triple-brooded. The male cannot always be certain that he has fathered the brood he raises, for extra-pair copulations have been observed, as has cloaca-pecking.

[*Nectarinia famosa*.

Photo Access]

16 mm recorded for eggs of the Long-billed Spiderhunter. The smallest eggs are those of the Crimson Sunbird, with dimensions of 12.2–17.3 × 10.2–12.7 mm, and those of the Handsome Sunbird, measuring 12.7–13.5 × 9.7–9.9 mm. Eggs vary in colour, from white to almost black; the ground colour is often decorated with a variety of spots, stripes, striations, blotches and other markings, the patterning frequently concentrated at the larger pole. The eggs of about 20% of nectariniids have not been described.

Whereas incubation of the eggs is carried out by both sexes of the spiderhunters, the eggs of sunbirds are nearly always incubated by the female alone, although there are reports of males of the Collared Sunbird and the Copper Sunbird sitting on eggs. Incubation usually lasts for about two weeks. The nestlings are naked, often black, or covered with short grey down, the interior

of the mouth being yellow, orange or red, without dark spots. Collared Sunbird nestlings have black down, sometimes with iridescent green on the head and mantle, and the nestling of Reichenbach's Sunbird is olive above and yellow below, with a grey throat. Those of the Southern Double-collared Sunbird are dark pink with a white gape and a dark-tipped dark horn bill. Females do the bulk of the work in the provisioning of the young, but the males often help, particularly after the offspring have fledged. Often, the fledglings return to roost in the nest for up to two weeks after their first flights.

Fledging success of the Seychelles Sunbird is 44.4–75.8%. The breeding biology of the Palestine Sunbird has been well studied. This species achieves a hatching rate of 67%, and in one study 47% of eggs laid produced fledglings. Clutches of three eggs were the most successful, returning an average of 1.5 young. Losses of eggs were due to infertility, desertion, breakage and embryonic deaths, and chicks were lost to predation, disturbance, infanticide and starvation.

A common cause of nest failure is parasitism by cuckoos, honeyguides (Indicatoridae) or honeybirds. In Africa, the Diederik Cuckoo has been recorded as parasitizing the Bronze Sunbird, the Mariqua Sunbird and the Copper Sunbird. Klaas's Cuckoo (*Chrysococcyx klaas*) is a brood parasite of the Collared, Orange-breasted, Green-headed, Cameroon, Western Olive, Amethyst, Scarlet-chested, Tacazze, Bronze, Malachite, Southern Double-collared, Greater Double-collared, Mariqua, Variable, Dusky and Copper Sunbirds. The African Emerald Cuckoo (*Chrysococcyx cupreus*) lays its eggs in nests of Newton's, Eastern Olive, Western Olive, Scarlet-chested, Amethyst and Copper Sunbirds, and the Red-chested Cuckoo (*Cuculus solitarius*) is known to parasitize the Malachite Sunbird and the Olive-bellied Sunbird. The Eastern Green-backed Honeyguide (*Prodotiscus zambesiae*) lays in nests of the Amethyst Sunbird, and the closely related Western Green-backed Honeyguide (*Prodotiscus insignis*) similarly parasitizes the Olive-bellied Sunbird. Greater Honeyguides (*Indicator indicator*) parasitize the Scarlet-chested Sunbird, a pair of which was seen also to chase away a Brown-backed Honeyguide (*Prodotiscus regulus*), but nest parasitism of sunbirds by this latter species remains unproven. In addition, the young of an unidentified honeyguide has been found in the nest of a Western Olive Sunbird.

In Asia, the Plaintive Cuckoo (*Cacomantis merulinus*) parasitizes the Purple-rumped Sunbird and the Purple Sunbird.

Compared to most nectariniids, which raise one or two broods per year, the **Bronze Sunbird** is a prolific breeder. Near the Equator, it may raise four or five broods in a twelve-month period. Given that each breeding cycle takes 40–50 days, a particularly fecund pair may devote two-thirds of their adult life to the business of procreation. As with other sunbirds, the female Bronze Sunbird has the main responsibility for raising the young, but, as we see here, the male also assists with provisioning duties.

[*Nectarinia kilimensis arturi*,
Vumba, E Zimbabwe.
Photo: Geoff McIlhlon]

The Asian Emerald Cuckoo (*Chrysococcyx maculatus*) lays in nests of Gould's, Green-tailed and Crimson Sunbirds, and the Violet Cuckoo (*Chrysococcyx xanthorhynchus*) is a brood parasite of the Ruby-cheeked Sunbird and Brown-throated Sunbird. The Little Spiderhunter is parasitized by the Violet Cuckoo, the Asian Emerald Cuckoo, the Common Cuckoo (*Cuculus canorus*), the Large Hawk-cuckoo (*Cuculus sparveroides*) and Hodgson's Hawk-cuckoo (*Cuculus fugax*); adults of this spiderhunter were

seen to feed a semi-dependent fledgling Violet Cuckoo in Peninsular Malaysia in late June. The Streaked Spiderhunter is likewise exploited by the Large Hawk-cuckoo, the Indian Cuckoo (*Cuculus micropterus*), the Common Cuckoo and the Asian Lesser Cuckoo (*Cuculus poliocephalus*).

Finally, there is one nectariniid species in Australia, the Olive-backed Sunbird. This, too, is host to several parasitic cuckoos, in this case the Shining (*Chrysococcyx lucidus*) and Horsfield's Bronze-cuckoos (*Chrysococcyx basalis*) and the race *russatus* of the Little Bronze-cuckoo (*Chrysococcyx minutillus*).

Movements

For a little under half of all species in this family, there is no certain record of movements. Whether such species are truly sedentary or whether the impression given is due merely to a lack of knowledge will be revealed only by further research. In those instances where nectariniids are known to undertake movements, these are often complex and little understood, and they vary within a species from one area to another.

Altitudinal shifts in response to seasonal changes in weather conditions are reported for species breeding at higher elevations. This phenomenon is particularly noticeable in the Himalayan region, where five species of *Aethopyga*, including Gould's, Green-tailed and Fire-tailed Sunbirds, make such movements, as does the Streaked Spiderhunter. Similar elevational displacements are recorded also in the Nilgiris of southern India, involving the Crimson-backed Sunbird and the Little Spiderhunter. The latter has been found to move altitudinally on Mount Mulu, in northern Borneo.

In Africa, the Collared Sunbird is recorded as making vertical movements in the Drakensbergs of South Africa, although not over the rest of its large range in that continent. Still in South Africa, the Orange-breasted Sunbird moves at least 320 m upwards during the austral summer in response to flower availability, and in the same country the Greater Double-collared Sunbird

The nestling period of the **Olive-backed Sunbird** lasts 13–16 days; judging from its largely olive and yellow juvenile plumage, this chick is probably only a few days short of fledging. There may be only one nestling in this brood, which could be because the female laid only a single egg or because one or two other chicks have perished. In Borneo, the normal clutch size is two, but only one chick usually fledges. Predation is a common cause of the other chick's demise: predators include monitor lizards (*Varanus*) and possibly ground squirrels (*Sciuridae*) and rats (*Rattus*).

[*Cinnyris jugularis frenatus*, Coquette Point, estuary of Johnstone River, NE Queensland, Australia. Photo: Stanley Breeden/Lochman Transparencies]

Rather surprisingly for a species distributed across much of sub-Saharan Africa, there is no solid information regarding the duration of the incubation or nestling periods of the **Common Purple-banded Sunbird**. What is known, however, is that both parents feed the nestlings. These photos offer a striking example of the contrast in plumage between the drab female (left) and the resplendent male (right). This pair's nest is fairly typical of the species: an oval construction, usually suspended from a branch, extensively decorated and camouflaged with leaves and lichen.

[*Cinnyris bifasciatus microrhynchus*, Nkwaleni Valley, KwaZulu-Natal, South Africa. Photos: Guy Upfold]

In common with most passerines, nectariniid nestlings excrete their alimentary waste encased in gelatinous white faecal sacs. In order to avoid contaminating the interior of the nest and attracting the attention of predators, adult sunbirds must extract and remove each sac as soon as the nestling produces it. This male **Black-throated Sunbird** is deftly removing the faecal sac prior to disposing of it at a safe distance from the nest. Such nest sanitation activity is particularly common in species with open nests that are especially vulnerable to predation.

[*Aethopyga saturata wrayi*,
Fraser's Hill,
Peninsular Malaysia.
Photo: Jimmy Chew]

wanders into and out of mountains in search of food. On Mount Cameroon, in West Africa, the Cameroon Sunbird moves altitudinally with the seasons. On the same mountain, the Northern Double-collared Sunbird moves down from its breeding area during the wet season in July to September, and it is absent also from Mount Elgon, in Kenya, at certain times. The Tacazze Sunbird shifts altitude on Mount Elgon and leaves mountains in southern Sudan when its main foodplant, *Lobelia*, is not in flower. Similarly, the Malachite, Red-tufted and Golden-winged Sunbirds have been demonstrated to make such movements in connection with the flowering of their favoured plants. In the Middle East, the nominate race of the Palestine Sunbird is an altitudinal migrant in Jordan, Saudi Arabia and Oman, and in Sudan the subspecies *decorsei* moves to higher levels in September–January to breed on Jebel Marra.

Movements associated with rains are common in Africa. One example is that of the Pygmy Sunbird, which in West Africa migrates during the dry season southwards from the Sahel to the savannas of Ghana, Togo and Nigeria, where it breeds in October–April or, in Ghana, sometimes as early as August. The pattern of movements, however, is not straightforward, as the species is present in north-west Nigeria only in the rains, presumably as a visitor from south-west Niger. It may also move from Sudan to the grasslands of Uelle, in DR Congo, during late December to March, and is a breeding visitor to north-west Uganda in October–March. This sunbird is known to gather in loose premigratory flocks of 20–30 individuals. It is also somewhat nomadic, moving in response to food supply. Another example is provided by the Scarlet-chested Sunbird, which exhibits a variety of movement patterns in different parts of its range, being recorded as sedentary, nomadic and migratory, both laterally and altitudinally. In West Africa it apparently moves north with the rains, occurring in Mauritania mostly during the wet season. It is known to move into both Kenya and Zimbabwe during dry periods, and in Namibia it is present during November–April. In the far northern parts of West Africa the Beautiful Sunbird arrives with the rains and proceeds to breed, and the Splendid Sunbird is similarly only

a wet-season visitor to the savannas of that region. The Southern Double-collared Sunbird is absent from the arid western region of South Africa during July–December, and is found in Eastern Cape Province during May–November. Likewise, the Mariqua Sunbird leaves the arid Kalahari during droughts. The White-breasted Sunbird exhibits a rather complex pattern of movements, in part associated with the rainfall regime. It moves during the dry period from the more arid southerly areas of southern Africa,

In most nectariniids for which data are available, young birds become independent a few weeks after fledging. During this period, the parents will continue to feed their offspring, as seen with these **Eastern Olive Sunbirds**. The link of sunbird fledglings with their natal patch remains strong; this individual is perched atop the nest in which it hatched and it will probably roost there until it feels sufficiently confident to leave its parents' territory. The Eastern Olive Sunbird is one of four nectariniids known to exhibit lekking behaviour. Leks contain 10–20 singing males that perform fluttering display flights and compete for the highest perches. Unusually for a lekking species, the male Eastern Olive Sunbird does not entirely neglect his parental responsibilities, for he joins in feeding the nestlings.

[*Cyanomitra olivacea*
olivacea,
Eshowe, KwaZulu-Natal,
South Africa.
Photo: Guy Upfold]

Once young nectariniids have fledged, the focus of the parental role shifts from provisioning their offspring towards preparing them for an independent life. Adults continue to feed fledglings for a couple of weeks, during which time they will gradually venture further from the nest. This female **Ruby-cheeked Sunbird** is feeding the well-grown fledgling away from the nest, familiarizing it with its wider surroundings.

[*Chalcoparia singalensis singalensis*,

Photo: Ong Kiem Sian]

where it breeds in the austral summer, to the wetter eastern and northern parts of its range. If there is further rainfall in the summer, it may spend the non-breeding season in areas farther west. Passage has been recorded in north Botswana, where White-breasted Sunbirds have been observed to be moving north-eastwards in April. In some areas, this species seems to be nomadic. The Dusky Sunbird is known to irrupt into Western Cape Province of South Africa in response to droughts.

Patterns of movement made by the Variable Sunbird are similarly complex, and the species is regarded as being variously resident, nomadic and a partial intra-African migrant in different areas. In Nigeria, it is resident in coastal savanna in the south, but elsewhere in southern Nigeria it is absent during the April–October rains, when it is present in the north of the country. Passage is recorded in northern Nigeria in April–July, with a return in September. The Copper Sunbird is another species that moves into the northerly savannas of West Africa to breed in the wet season in April–October, and occurs in Mauritania only in the wet from August to October. In Madagascar, the Long-billed Green Sunbird is absent from the dry forest in the south-west of the island for long periods. Finally, in Australia, the Olive-backed Sunbird is more abundant around Townsville, in northern Queensland, in the wet summer months than it is in the dry winter months.

Movements that are directly linked with flowering patterns of certain plants have been observed. In Mauritania, the Pygmy Sunbird moves from one area to another in relation to the abundance of mistletoes that parasitize acacia trees. The Beautiful Sunbird and the Shining Sunbird make similar displacements in relation to the supply of mistletoes, and in south Sudan the Tacazze Sunbird is absent from mountains when the *Lobelia* plants are not in flower. The Souimanga Sunbird of Madagascar is abundant when certain plants, such as *Aloe* and *Kalanchoe*, are in flower. At least eleven other nectariniid species are recorded as moving in relation to flowering events, but without specific plants being mentioned.

Few details are available of the recorded distances covered by dispersing or migrating sunbirds. The Olive-backed Sunbird has reached Booby Island, in the Torres Strait, a distance of 24 km from the nearest point in its known range, and the Seychelles Sunbird has colonized Aride Island from Cousin Island, 20 km distant. Some Gould's Sunbirds move from east Nagaland, in

north-east India, and southern China south to Manipur, north Cachar and Myanmar in the non-breeding season, and others travel between mountains in north Thailand. The Fire-tailed Sunbird has been recorded once as a migrant in Thailand, well south of its known breeding range. In addition, a total of 3300 Fire-tailed Sunbirds and 250 Gould's Sunbirds were recorded moving north along a ridge in western Yunnan, China, in November. At least 22 Streaked Spiderhunters were seen moving along another ridge in the same region, also in November.

In the African region, there are influxes of the Nile Valley Sunbird into Egypt in October–March. This species also arrives

Brood parasitism is a frequent problem for breeding nectariniids. Depending on location, the parasites include various species of cuckoo (*Cuculidae*) and honeyguides (*Indicatoridae*). This male **Cameroon Sunbird** has been duped into raising a Klaas's Cuckoo (*Chrysococcyx klaas*), a species that has been recorded parasitizing 15 other sunbird species. Parasitism results in partial or complete nest failure as the female parasite usually ejects one of the host species' eggs as she lays her own and the nestling parasite often dispatches any host species chick in similar fashion.

[*Cyanomitra oritis banoensis*,
Belegete, Obudu District,
Cross River State,
SE Nigeria.

Many nectariniids visit gardens to investigate the wide range of additional, often exotic, foodstuffs that are available. Such close contact enables human observers to become familiar with such vividly coloured species as the spectacular **Temminck's Sunbird**. Some sunbird species take their relationship with man one or two steps further, drinking at birdbaths, foraging for insects at windows, or locating their nests on buildings. Some nectariniids are lauded for pollinating commercially important plants; others are treated as pests for assisting the spread of parasitic plants.

in Saudi Arabia, north of the Tropic of Cancer, from mid-October, and it is present in Oman from November to February. Non-breeding individuals, including perhaps some from Arabia, are present in Somalia and eastern Ethiopia from September to May. South of the equator in Africa, the Amethyst Sunbird has been recorded as moving distances of up to 120 km. In southern Africa, there are documented movements by the Scarlet-chested Sunbird of as much as 360 km, whereas the Malachite Sunbird in the same region has been recorded as migrating up to 500 km. In Malawi, the Red-tufted Sunbird is absent from the Nyika Plateau in May–June, and in north Tanzania it is recorded as a vagrant on the North Pare Mountains, 60 km from the nearest part of its known range, namely Kilimanjaro. Other confirmed movements involve the Golden-winged Sunbird, recorded as migrating up to 101 km in Kenya, this also including an altitudinal shift; the Miombo Double-collared Sunbird, which has moved up to 29 km in Zimbabwe; and the Copper Sunbird, for which displacements of up to 43 km have been documented in South Africa.

Relationship with Man

Sunbirds are common visitors to gardens, where their grace and charm, and the beauty of those species with iridescent plumage, are much appreciated. Common garden flowers, such as *Hibiscus* and *Strelitzia*, are often planted in order to attract them, but only a few species, such as the Collared, Mariqua, Variable and White-breasted Sunbirds, come to drink at birdbaths. The Palestine Sunbird is known in Arabic as *Sultan el-Zahar*, the “King of the flowers”, a name which could be applied to the majority of the members of the family.

Some members of the Nectariniidae associate with human habitations, where they take advantage of the opportunities for nesting provided by houses and other buildings (see Breeding). Others often visit dwellings in order to exploit foraging opportunities, such as insects at window panes (see Food and Feeding). In these circumstances, they are again often welcomed by their human hosts.

The visits of both sunbirds and spiderhunters to the flowers of plants of economic importance contribute to the pollination of these, and this can be significant. This same habit, however, also

assists the spread of parasitic mistletoes. As a consequence, the Scarlet-chested Sunbird is treated as a pest in West African cocoa plantations, where the mistletoe *Tapinanthus bangwensis* reduces yields. The Purple Sunbird is similarly implicated in the spread of mistletoes in commercial *Gmelina*, *Shorea* and teak plantations in India. The Purple Sunbird and the Purple-rumped Sunbird are also pests in vineyards, where they damage the fruit. Other direct damage is caused by the Scarlet-chested Sunbird, in this case to commercially grown protea flowers. On the other hand, the sunbirds and spiderhunters consume large quantities of insects, a fact which renders them beneficial to man, since many of these insects are likely to be pests or human-biters and some of them are conveyors of disease.

In Borneo, spiderhunters are considered by the Dusun people of Merimbun, in Brunei, to be a good omen in all situations when they are seen flying from right to left. One calling from the left-hand side of a person, however, can in certain circumstances be a bad omen, but a spiderhunter heard to call from the right is an encouraging augury to a hunter.

Status and Conservation

On the whole, sunbirds and spiderhunters are adaptable to habitat changes if these are not too severe. Although many of the species are attractively plumaged, they are not regarded as being desirable as cagebirds. This is perhaps because they are not known as songsters pleasing to the human ear, in addition to which they may be difficult to keep in captivity, and they have therefore been saved from the depredations of the cagebird trade. Provided that flowering plants are available to provide nectar and other plant products, and as a habitat for their invertebrate prey, the members of this family will tolerate variable degrees of degradation of their primary habitat. As a consequence, many species spread into plantations, orchards, other agricultural areas, gardens and a variety of secondary habitat types as humans encroach upon their natural habitats. With so little known about the requirements of the Nectariniidae for optimal breeding and survival, it is very difficult to quantify the effects of the habitat degradation that result in a species shifting into man-made habitats for part or even all of its life.

A fair number of nectariniids qualify as restricted-range species, the extent of their range being less than 50,000 km². The **Regal Sunbird** and **Stuhlmann's Double-collared Sunbird** are two of the four sunbird species that occur only within the Albertine Rift Mountains Endemic Bird Area, which spans Burundi, Rwanda, Tanzania, Uganda and DR Congo. The Regal Sunbird is locally common throughout much of its small range, while Stuhlmann's Double-collared Sunbird is abundant at certain sites, particularly at altitudes above 2750 m. Habitats frequented by both species include montane forest, bamboo and clearings; the first two of these are among the key habitat types in the Albertine Rift mountains. In addition to the four sunbirds, some 32 other restricted-range species occur in this EBA. It contains several important protected areas, including parks well known for the conservation of the mountain gorilla (*Gorilla gorilla berengii*) but the remaining habitat continues to be threatened by deforestation, prompted by the price of timber and the need for agricultural land.

The stunning **Crimson-backed Sunbird** is a restricted-range species, occurring only in the Western Ghats Endemic Bird Area of western India.

Reports of this species occurring, and even breeding, in Sri Lanka in the early twentieth century are considered to be erroneous. The Crimson-backed Sunbird is locally common and inhabits evergreen forest, shaded plantations, secondary growth and gardens, particularly in the foothills. The species' ability to utilize habitats that have been modified by man reassures conservationists about its status, so that its future is currently considered secure.

[*Leptocoma minima*, Backwoods Camp, Goa, India.

Photo: Greg & Yvonne Dean/World Wildlife Images]

The common occurrence or, indeed, even the mere presence of a species in areas of modified habitat may give the appearance that a secure, stable, adaptable population of that species is involved. The population concerned may, however, be living in sub-optimal conditions for breeding or overall survival, and only through long-term studies can the true situation be elucidated. Preservation of the species' perceived natural habitat must be a top priority if there is to be some degree of confidence in its continued existence.

Of the 132 species of sunbird and spiderhunter currently recognized, only seven, or 5.3%, are considered by BirdLife International to be globally threatened. Three of these are classified as Endangered and four as Vulnerable, although one presently placed in the latter conservation category may require an uplisting to the category of Endangered. A further eight nectariniids, 6.1%, are listed as Near-threatened. Thus, there is some concern for 15 species, equivalent to about 11.4% of the members of the family. One of the Endangered species is from Kenya and Tanzania, another from east Tanzania and the third from Indonesia. Of the Vulnerable species, one is from the DRCongo, one is confined to the Gulf of Guinea republic of São Tomé and Príncipe, and two are restricted to Tanzania. Four of the eight Near-threatened species hail from the Afrotropical Region, one of these from Cameroon and Bioko, another from Tanzania, a third from South Africa and Mozambique, and the fourth from Kenya, Tanzania, Mozambique and perhaps Zimbabwe. The remaining four are Asian, one from the Sunda region and three from the south Philippine island of Mindanao.

The Amani Sunbird is regarded as Endangered on account of its very small and fragmented range. It occurs only in the Arabuko-Sokoke Forest of Kenya and, in Tanzania, in four areas in the East Usambara Mountains and two areas in the Udzungwa Mountains. This species' global population, which is decreasing, is estimated to lie in the range 10,000–19,999 individuals, and its total geographical range is estimated at 870 km². Although forest-dependent, it has been recorded in very degraded forest, clearings and gardens. Destruction of forest, often carried out illegally, appears to be the principal threat to this sunbird, although competition with a congener, the Collared Sunbird, may also be a factor. Long-term forest conservation through sustainable management and community participation is underway in Arabuko-Sokoke. In Tanzania, there are three active conservation and

development projects in the East Usambaras, together covering at least 121 km²; the Amani Sunbird's known locations in the Udzungwas are relatively well protected by their isolation.

Not too far away, in east Tanzania, another Endangered sunbird survives in the Uluguru Mountains. This is Loveridge's Sunbird, which is restricted to threatened habitats within an elevational range of 1200–2580 m. Its global population, estimated at probably 37,000 individuals, is found entirely within three forest reserves covering a total surface area of some 260 km². There is a need for field research on this species, with the aim of determining the extent to which it is capable of tolerating further degradation of its habitat.

In Asia, the last of the three Endangered nectariniids, the Elegant Sunbird, is confined to the very small island of Sangihe, north of Sulawesi. One specimen was apparently taken on nearby Siau in 1866. Its population, estimated at 2500–9999 individuals, is severely fragmented, and is continuing to decline as a result of habitat loss and degradation. This sunbird's total range is estimated to be 560 km², within which it has been recorded from Talawid Atas, Kedang, Mount Awu, Petta, Manganitu, Mount Sahendaruman, Mount Sahengbalira, Mount Palenti, Kentuhang, Ulung Peliang, Tabukan and Tahuna. In 1998–1999, it was the most commonly encountered forest bird species at Mount Sahendaruman, suggesting locally high population densities, but its absence from large areas of Sangihe indicates that, overall, its numbers are relatively small. The Elegant Sunbird is an inhabitant of primary forest, forest edge, adjacent low scrub and plantations, but is present in the last-mentioned habitat only if hardwoods persist in the vicinity and a scrubby understorey is available; it is found at elevations from 75 m to 1000 m. The tiny remnant of primary forest that exists on Sangihe receives inadequate protection and continues to suffer from agricultural encroachment at its lower fringes. The forest on Mount Sahendaruman is nominally conserved. Since 1995, fieldwork and conservation-awareness programmes have been conducted, and ideas developed for future land use, through agreements between interested parties. There are plans to reclassify the 4 km² of "protection forest" on Mount Sahengbalira as a wildlife reserve, and some forest in the Kentuhang valley is protected as the watershed for a hydro-electric scheme. It has been proposed that a permanent presence of forestry staff be established on the island.

Rockefeller's Sunbird is poorly known and is thought to have a very small population. It is thus classified as Vulnerable, but its conservation category may need to be upgraded to that of Endangered. It has a stable population of 250–999 individuals, and its

Small islands are often replete with endemic birds, and Sumba, in the Lesser Sundas of Indonesia, is no exception.

The **Apricot-breasted Sunbird** is a restricted-range species that occurs only in the Endemic Bird Area formed by this 11,000 km² island. This species is very common at the forest edge, and in secondary forest, cultivation and scrub, particularly in the lowlands. Its abundance and adaptable habitat tastes mean that it is not currently considered to be at risk of extinction.

[*Cinnyris buettikoferi*, Sumba, Lesser Sundas. Photo: Roland Seitre]

The island of Socotra, situated off the north-east coast of Somalia, holds several endemic bird species and thus forms an Endemic Bird Area.

The endemic forms include the **Socotra Sunbird**, seen here perching on *Trichocalyx obovatus* (Acanthaceae), a plant classed as Data-deficient. This restricted-range nectariniid is relatively common, with a population of around 11,000 pairs occurring at a density of 6–12 birds/km². It is present pretty well wherever there is vegetation. Although it is not currently considered to be globally threatened, it could in the future face a considerable threat from the results of overgrazing by goats and cattle.

[*Chalcomitra balfouri*, Wadi Ayhaft, Socotra. Photo: Hanne & Jens Eriksen]

estimated range is 9800 km². It occurs in the northern Itombwe Mountains and mountains to the north and west of Lake Kivu, in the eastern DR Congo, and there are single unconfirmed records from Rwegura, in Burundi, and Nyungwe, in Rwanda. This sunbird inhabits bamboo forest at higher altitudes, especially streamside thickets, and it is found also in montane forest down to 2050 m and in Afro-alpine moorland. Within the Kahuzi-Biéga National Park, west of Lake Kivu, its habitat is protected, although armed militias carried out illegal hunting, logging and mining there in 2001. The Itombwe Mountains receive no protection.

The Banded Sunbird is considered Vulnerable, having a decreasing population estimated at 10,000–19,999 individuals, and a range estimate of 6700 km². It is endemic in Tanzania, being found in five areas of forest in the east of the country: the mountains of Usambara, Nguu, Nguru, Uluguru and Udzungwa, the last including the Ndundulu Mountains. It is common in parts of the Usambaras, but elsewhere is uncommon to rare. It occurs in rainforest at middle altitudes, and more frequently in large glades, disturbed or secondary forest with some surviving large trees, gardens and exotic plantations, but is probably dependent on adjacent primary forest. This nectariniid is threatened over most of its range by forest loss and degradation, resulting from clearance for agriculture, replacement of natural forest with plantations, and tree-cutting for timber and firewood. In the Usambaras and the Ulugurus, the large human population is placing ever greater pressure on land and the forests are fragmented. In the Ulugurus the inaccessible nature of the terrain effectively protects the main block of montane forest, although this covers no more than about 120 km²; conservation projects here are aimed at assisting local initiatives and increasing involvement of local communities in forest management. Forests in the Nguru Mountains, because of their precipitous terrain and the comparatively small human population, are believed not to be currently threatened. In the Usambaras, the East Usambara Catchment Forest Project and the existence of other reserves, such as Mount Nilo Forest Reserve, afford protection to a significant area of middle-altitude forest. In the Udzungwas, the Banded Sunbird is found in the Udzungwa Mountains National Park and the West Kilombero Scarp Forest Reserve.

In terms of its conservation status, the Sao Tome Sunbird is regarded as Vulnerable because it appears to have a small, though stable, population in the range 250–999 individuals, and a limited area of suitable primary-forest habitat estimated at 340 km² in extent. It is confined to the island of São Tomé, in the Gulf of Guinea, where it occurs on the central massif, north towards Ponta Figo, south-west to the area around the rivers São Miguel, Xufexufe and Quija, and east to Formoso Grande and the Formoso Pequeno and the valley of the Ana Chaves river. Although locally common, its total population is probably small as the island contains only a relatively small area of available habitat. The Sao Tome Sunbird occurs in both lowland and montane primary forest up to at least 2000 m, and is occasionally observed in for-

The **Seychelles Sunbird** is the only nectariniid that is to be found in the Seychelles. This restricted-range species occurs in the Granitic Seychelles Endemic Bird Area. It can be found in almost all habitats, natural or man-made, up to altitudes of around 900 m. Generally common and not considered globally threatened, the Seychelles Sunbird may be expanding its range, as birds ringed on Cousin Island were found subsequently to have recolonized Aride. This species is one of the less spectacular members of the Nectariniidae, the male's only colourful areas being a glossy blue throat and yellow, orange or red pectoral tufts. The female lacks even these modest adornments.

[*Cinnyris dussumieri*, Frégate, Seychelles. Photo: Robert Cheke]

The **Mayotte Sunbird** is one of three restricted-range nectariniids that occur in the Comoro Islands Endemic Bird Area. It has a tiny range, restricted only to the island of Mayotte and nearby islets. Nevertheless, it is not considered globally threatened as it is a common inhabitant of open areas as well as forest edge, so is at no particular risk from deforestation. A similar situation applies to this species' congeners elsewhere in the Endemic Bird Area: the Anjouan Sunbird (*Cinnyris comorensis*) is common on the island of Anjouan; and Humblot's Sunbird (*C. humbloti*) is common on Grand Comoro and Mohéli.

[*Cinnyris coquerellii*, Mayotte, Comoro Islands. Photo: Roland Seitre]

est-edge cultivation. Large areas of lowland and middle-altitude forest have already been lost to cocoa and coffee plantations, while the number of small farms has increased, and tree clearance has accelerated as a result of land privatization. Clearance of forest, not only for cultivation, but also for timber and fuelwood supplies, is an additional threat, as also are road developments along the east and west coasts allowing increased human access to previously remote areas. There are proposals to protect the primary forest by designating it an ecological zone and a national park, but at present the forest remains unprotected. A law providing for the listing of protected areas and for the protection of threatened species has still to be ratified.

Currently listed as Vulnerable, the Rufous-winged Sunbird has a small range and is known from only eight locations, all of which, fortunately, lie within well-protected areas. In intervening, non-protected areas, any suitable habitat is probably declining in extent or quality as a result of deforestation and forest degradation. This sunbird is found only in Tanzania, occurring in the forests of Mwanihana and Iwonde, both in Udzungwa Mountains National Park, and in forests at Ukami, Ndundulu and Nymbanitu, in the West Kilombero Scarp Forest Reserve, and in Katemele, Kiranzi-Kitungulu and Uzungwa Scarp Forest Reserves. Its decreasing population is estimated to number 10,000–19,999 individuals, and its known range covers 3360 km². It is found in the forest interior and at the edges of gaps in natural forest, most commonly at 1500–1700 m, but it descends to lower elevations, below 1500 m, during the cooler non-breeding season in June–August. The Rufous-winged Sunbird would face serious danger if protected-area status were to be removed from the forests which it inhabits, particularly at lower elevations.

The Plain-backed Sunbird is considered Near-threatened. It has a disjunct distribution in the coastal lowlands of Kenya and north-eastern Tanzania, in Mozambique and in Zimbabwe. Generally uncommon in forest below 500 m, but ascending to 1000 m in the East Usambaras of Tanzania, it reaches its highest density in Arabuko-Sokoke Forest, in Kenya. In Tanzania, it occurs also southwards to Kiono Forest Reserve, where it is common, and Pande Forest Reserve, where it is rare. In southern Mozambique it is uncommon, with a total population of fewer than 500 individuals, all in dense coastal forest and ironwood (*Androschachys*) forests, and declining as a result of deforestation. There

are few records from south-eastern Zimbabwe, from *Acacia* bush, riverine thicket and riparian forest, but there is a possibility that some of these, at least, may be the result of misidentification of the Variable Sunbird. The Plain-backed Sunbird is a little-known species, and nowhere common. Its population is declining in some areas, and the species may be at risk from clearance of lowland forest throughout its range.

Another *Anthreptes* species, the Red-throated Sunbird, is likewise classed as Near-threatened. It is restricted to the lowlands of south Tenasserim, in southernmost Myanmar, the Malay Pe-

Eight species of nectariniid, representing about 6% of the family, are considered Near-threatened at the global level. While such species are not immediate priorities for conservation concern, they are "birds to watch", as habitat destruction or deterioration, among other pressures, could cause populations to decline to serious levels. One such example is the **Plain-backed Sunbird**, which has a fragmented distribution in the coastal lowlands from Kenya south to South Africa. Nowhere is it common, and its near-dependence on forest means that it is particularly susceptible to habitat transformation.

[*Anthreptes reichenowi yokanae*, Arabuko-Sokoke Forest Reserve, E Kenya. Photo: A. P. Leventis]

The **Red-throated Sunbird** is considered rare to uncommon throughout its range in South-east Asia, Sumatra, Borneo and, possibly, Palawan, in the west Philippines. Its preference for lowland forest below 900 m places it at risk from the widespread deforestation going on in the region. However, it also inhabits less pristine habitat, such as secondary growth, plantations and coastal vegetation. This tolerance of sub-optimal habitat has led conservationists to consider that the species is not under immediate threat of extinction, but it is currently listed as Near-threatened.

[*Anthreptes rhodolaemus*, Panti Forest, Peninsular Malaysia. Photo: Morten Strange]

ninsula, Sumatra and Borneo, although it has possibly been recorded also on Palawan, in the west Philippines. It is uncommon to rare throughout its range, where it occurs in broadleaf evergreen forest to 900 m. Destruction of lowland forest in southern Asia gives cause for concern, but this species' use of submontane and secondary forests, forest edge and plantations implies that it is not immediately threatened.

Ursula's Sunbird is found in forest near Dschang, on Mount Manenguba, Mount Nlonako and Mount Kupé, in the Bakossi Mountains and Rumpi Hills and on Mount Cameroon, all in west Cameroon, and also on Bioko, which is part of Equatorial Guinea. On Bioko there are only a few records, all from primary forest between 1000 m and 1200 m. In Cameroon, it occurs from 950 m to 2050 m in mature forest and forest clearings. In 1991 and 1992 it was common in the Rumpi Hills, and in 1998 it was common down to at least 1100 m in the Bakossi Mountains; in the 1980s it was frequent to common on Mount Cameroon and Mount Nlonako, and throughout the 1990s it was common in all of the forest on Mount Kupé. As this species appears to be dependent on largely undisturbed forest within quite a small range, it is potentially at risk from further forest clearance and is classified as Near-threatened.

Two other *Cinnyris* species are placed in the conservation category of Near-threatened. One, Moreau's Sunbird, is restricted to Tanzania, where it has a small range in the Nguru, Nguu, Uvidunda, Ukaguru and Udzungwa Mountains, occurring in montane forest usually at 1300–1850 m, but at up to 2500 m in the Udzungwas. Healthy numbers of this sunbird have been found in the Nguu and Ukaguru Mountains. Owing to the precipitous terrain and the low human population density in the forests, this species' habitat is not immediately threatened. Moreau's Sunbird occurs within the well-protected Udzungwa Mountains National Park. As it appears to be forest-dependent, it is likely to be sensitive to destruction or degradation of forest habitat elsewhere in its limited range. The other Near-threatened *Cinnyris* species is found from Inhambane, in southern Mozambique, southwards to northern KwaZulu-Natal, in north-east South Africa. Here, Neergaard's Sunbird is a nomadic, sometimes common species of woodland, especially dry, dense forest on sandy soil at low elevations, but apparently avoiding fragmented coastal forest. Much of its range in KwaZulu-Natal is within nature reserves,

but in Mozambique its coastal-forest habitat is highly threatened, particularly by commercial logging and afforestation with non-native tree species.

All three of the remaining nectariniids currently considered to be Near-threatened are in the genus *Aethopyga*, and all are confined to the island of Mindanao, in the south Philippines. The

Three of the eight species of sunbird considered Near-threatened are endemic to the island of Mindanao, in the Philippines, and thus also qualify as restricted-range species. They include the **Apo Sunbird**, which is common in montane forest, usually above 1500 m. Forest at this elevation on Mindanao is relatively secure from anthropogenic pressure. This nectariniid's conservation classification is thus more of a precautionary measure, based on the species' limited distribution rather than being due to current threats to its population. The three subspecies of Apo Sunbird each inhabit different montane areas of Mindanao; one race was described as recently as 1997.

[*Aethopyga boltoni tibolii*, Baracatan, Davao, Mindanao, Philippines. Photo: Doug Wechsler/VIREO]

Even if *Lina's Sunbird* inhabited all the suitable remaining montane forest above 1200 m in eastern Mindanao, its entire global distribution would not exceed 770 km². This tiny range is the reason for its listing as Near-threatened. Realistically, it is not likely to become globally threatened in the short term, because it is common within largely inaccessible forests that contain few tree species of interest to the commercial logger, and that lie on slopes too steep to serve as agricultural land.

[*Aethopyga linaraborae*, Mt Pasian, Mindanao, Philippines.
Photo: Edward Vercruysee]

Seven of the 132 species of nectariniid are considered globally threatened. Of this group, six are African, while the other is Indonesian. Four are listed as Vulnerable and three as Endangered. The latter include the *Amani Sunbird*, a restricted-range species that occurs in just a handful of highly fragmented and declining populations across two Endemic Bird Areas in Kenya and Tanzania, its total area of occurrence being just 870 km². Fewer than 20,000 *Amani Sunbirds* are estimated to remain. Most populations are threatened by deforestation, and, possibly, by competition from the congeneric *Collared Sunbird* (*Anthodiaeta collaris*).

[*Anthodiaeta pallidigaster*, Arabuko-Sokoke Forest Reserve, Kenya.
Photo: Steve Garvie]

Grey-hooded Sunbird is fairly common to common above 1000 m in forest and forest edge, including at Mount Hilong-Hilong, Mount Kitanglad, Civolig, Daggayan, Mount Lamut, Mount Apo and Lake Sebu. It occupies a very small range, but its habitat is apparently secure at present. The Apo Sunbird is apparently fairly common above 1500 m in forest on Mount Malindang, Mount Kitanglad, Mount Apo, Mount Pasian, Lake Sebu, Mount Busa, Mount Matutum, Mount McKinley and Mount Parker. As with the previous species, its range is very small but its habitat appears to be secure. Finally, *Lina's Sunbird* is common in mossy forest above 1200 m on Mount Pasian, Mount Puting Bato and Mount Mayo, in the eastern provinces of Davao del Norte and Davao Oriental. Its total range may be as much as 770 km² if it occupies all available remaining habitat above 1200 m. It is believed unlikely that this species will become seriously threatened in the near future, as it occurs in rugged and inaccessible mountains lacking many commercial tree species and generally too steep for agricultural exploitation.

None of the ten species of spiderhunter is thought to be at any risk, at least in the immediate future. Nevertheless, several of them are, at best, uncommon. In the Malay Peninsula and the Greater Sundas, for instance, the Yellow-eared Spiderhunter is local and uncommon to rare and the Long-billed Spiderhunter generally scarce. Whitehead's Spiderhunter is confined to northern Borneo and was formerly rated as Near-threatened, but it has now been found to be locally common.

Genus *CHALCOPARIA* Cabanis, 1851

1. Ruby-cheeked Sunbird

Chalcoparia singalensis

French: Souimanga à joues rubis **Spanish:** Suimanga Carirrubí
German: Rubinwangen-Nektarvogel
Other common names: Rubycheek

Taxonomy. *Motacilla singalensis* J. F. Gmelin, 1789, Ceylon; error = Malacca, Peninsular Malaysia. Genus generally merged with *Anthreptes* in the past, but distinctive tongue morphology unique within family; possibly warrants placement in separate family or subfamily. Geographical variation not well marked; in addition, described race *rubiginentis* (from Cachar, in NE India) considered inseparable from *assamensis*, and *stellae* (from Trat Province, in S Thailand) indistinguishable from *koratensis*. Eleven subspecies recognized.

Subspecies and Distribution.

- C. s. assamensis* Kloss, 1930 – C Nepal (from Chitwan) E to NE India (S from Assam), Bangladesh, N Myanmar, N Thailand and S China (W & S Yunnan).
- C. s. internota* (Deignan, 1955) – S Myanmar and S Thailand (S to Isthmus of Kra).
- C. s. interposita* Robinson & Kloss, 1921 – peninsular Thailand S of Isthmus of Kra.
- C. s. koratensis* Kloss, 1918 – E Thailand and Indochina.
- C. s. singalensis* (J. F. Gmelin, 1789) – Peninsular Malaysia S from N Perak.
- C. s. sumatrana* Kloss, 1921 – mainland Sumatra and Belitung.
- C. s. panopsis* Oberholser, 1912 – islands off W coast of Sumatra.
- C. s. pallida* Chasen, 1935 – N Natuna Is.
- C. s. borneana* Kloss, 1921 – Borneo.
- C. s. bantenensis* (Hoogerwerf, 1967) – W Java.
- C. s. phoenicotis* (Temminck, 1822) – C & E Java.

Descriptive notes. 10–11 cm; male 8.2–9.1 g, female 8–6 g. Male nominate race is dark with brilliant emerald-green iridescence above; upperwing blackish, with blue iridescence on shoulder; tail black with some greenish-blue iridescence; ear-coverts and cheek copper, violet patch bordering throat; throat to upper breast chestnut-red, rest of underparts yellow; iris red; bill blackish; legs greenish-grey. Female is olive-green above, has upperwing dark, with yellow on wing-coverts and edges of remiges, cheek grey, throat and breast rufous, rest of underparts yellow. Juvenile differs from female in having yellow throat concolorous

with rest of underparts. Races differ mainly in coloration of underparts: *assamensis* male differs from nominate in having darker throat, less extensive red below; *internota* is darker than previous, has reddish-brown of throat and breast not clearly defined, yellow below more greenish-tinged; *interposita* male has less chestnut-red on throat and upper breast than nominate, and is less green; *koratensis* male has rufous on throat paler and less extensive than *assamensis*, and well separated from yellow of rest of underside; *sumatrana* male is more bluish above, and darker and more extensively rufous below than *assamensis*; *panopsis* male is as nominate, female has paler, more greenish upperparts and more brightly yellowish posterior underparts than nominate; *pallida* resembles nominate, but reddish below is paler, less extensive and less well defined; *borneana* of both sexes has rufous or chestnut-red of foreneck and upper breast deeper than *interposita*, is more yellow below than previous, also birds from S Borneo are slightly larger than those from N; *bantenensis* has throat and foreneck browner, and area of that colour on chin, throat and foreneck less extensive than in *koratensis*, much clearer greenish-yellow on underparts; *phoenicotis* has rufous of throat merging imperceptibly into yellow of underparts, green gloss on back darker than in *assamensis*, also juvenile less yellow below and duller (less bright olive-green) above than juvenile of last. **VOICE.** Song a shrill rising trill ending in short double note, followed by descending trill ending in 2 separated notes, “tírr-títí, trírrr, tírr, tírr”; another song described as rapid, high “swítí-tí-chí-chú, túsí-tít, swít-swít...”. Call, often in flight, a shrill chirp “seet-seet” or “tear-tear”; described also as thin, shrill, emphatic, upturned “tweest-wit”, second note much higher, also slurred “chúwéést”, and clipped “swít-(swít)”; soft “chí-wíp” by male.

Habitat. Various forest types, including mangroves, regenerating forest, and forest edge, also coastal and riverine vegetation, plantations, coconut groves and gardens. Sea-level to c. 1000 m.

Food and Feeding. Insects, including caterpillars, and probably spiders (Araneae); also fruit, pollen and nectar. Forages in upper storey, occasionally lower. Often feeds at spider webs. Probes flowers for nectar, and gleans insects from leaves.

Breeding. Nest-building in Feb (Mizoram) and laying end Mar to Jun in India; laying Mar and May–Aug in Myanmar, at least Mar–Aug in Malay Peninsula, and Feb–Jul in Java; in Borneo, laying Jan–May and Aug in N (Sabah), nest-building in Jun in S, and juveniles in Aug and Sept in NW (Sarawak) and Jun–Jul in S. Male feeds female in courtship. Nest shaggy and pear-shaped, with porch, made from cobwebs and various plant materials, including roots, fibres, fern stalks, dry grass and moss, suspended from end of drooping twigs of bush 2–8 m above ground, often under steep bank and never in exposed site. Clutch 2 eggs, pink, mauve, white or purplish-grey, marked with clouds, lines or speckles of various shades of brown, grey or purplish-black; no information on duration of incubation and nestling periods; nestlings and fledglings tended by both parents. Nests apparently parasitized by Violet Cuckoo (*Chrysococcyx xanthorhynchus*) in Thailand.

Movements. None recorded. Possibly crosses water to reach Singapore.

Status and Conservation. Not globally threatened. Rare in Nepal and Bhutan, but locally common in other parts of NE Indian Subcontinent; common in Thailand and uncommon to common in Malay Peninsula; common in Sabah, but less common in other parts of Borneo; widespread but uncommon in Sumatra and Java. Reports of this species (race *assamensis*) from N & C India (Uttaranchal and N Andra Pradesh) require confirmation. Occurs in a good many protected areas throughout its range.

Bibliography. Ali & Ripley (1974), Birand & Pawar (2004), Cheke & Mann (2001), Étchécopar & Hùe (1983), Fleming & Traylor (1964), Fleming *et al.* (1976), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949, 1950, 1967a), Inskipp & Inskipp (1985), MacKinnon & Phillipps (1993), Mann (1996, 2002, 2008), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), Oberholser (1912), Rasmussen & Anderton (2005b), Ripley (1950), Robson (1998, 2000b, 2004b), Sheldon *et al.* (2001), Smythies (1960, 1986), Smythies & Cranbrook (1981), Smythies & Davison (1999), Wells (2007).

Genus *DELEORNIS* Wolters, 1977

2. Scarlet-tufted Sunbird

Deleornis fraseri

French: Souimanga de Fraser **German:** Laubnektarvogel **Spanish:** Suimanga de Fraser
Other common names: Brown/Fraser's Sunbird

Taxonomy. *Anthreptes fraseri* Jardine and Selby, 1843, Bioko.

Formerly placed in genus *Anthreptes*. Sometimes treated as conspecific with *D. axillaris*, but the two meet in SW DR Congo apparently without intergrading. Three subspecies recognized.

Subspecies and Distribution.

- D. f. idius* (Oberholser, 1899) – SW Guinea and Sierra Leone E to Togo; also recorded in extreme S Mali.
- D. f. cameroonensis* (Bannerman, 1921) – S Nigeria E to SW Central African Republic, S to PR Congo, W DR Congo and NW Angola.
- D. f. fraseri* (Jardine & Selby, 1843) – Bioko I (Fernando Póo).

Descriptive notes. 11.5–12.7 cm; 10.5–15.3 g.

A large dull green sunbird, with long straight bill curved only at tip. Male nominate race is uniformly bright olive-green above, with upperwing and tail brown, outer webs edged yellow-olive; yellow-olive below, pectoral tufts orange-red with yellow at base, axillaries pale yellow, underwing-coverts greyish-white; iris hazel, pale yellow or white eyering; bill dull brown, base of lower mandible olive-yellow; legs olive, claws yellowish-horn. Distinguished from *Cinnyris batesi* and *Anthreptes seimundi* and from female of *Anthreptes rectirostris* mainly by long straight bill (curved only at very tip) and presence of pectoral tufts. Female is as male, but smaller and without pectoral tufts. Juvenile differs from adult in being all pale olive above, paler below, with yellow wash on belly, darker bill. Race *cameroonensis* has duller olive-green underparts with less yellow tinge than nominate; *idius* is smallest and darkest, with darker brown (less green) tail, also iris reddish-brown, upper mandible horn, lower mandible yellowish-horn, and legs greenish-slate with flesh-coloured claws. **VOICE.** Song a series of high-pitched “tserr-tseep” (or just “tseep”) repeated every second, or “tserr” followed by 4–5 “tseep” notes, the whole sequence repeated at c. 5-second intervals. Also, “tzuu-zui-zui-zui”. Calls squeaks, e.g. “psi”.

Habitat. Forest; also in cultivations such as cocoa plantations within forests, and at forest fringes.

Food and Feeding. Small insects and spiders (Araneae); likely to be occasionally frugivorous, but no records of fruits taken, nor of nectarivory. Forages in groups of up to ten individuals; joins mixed-species parties. Mainly in middle storey.

Breeding. Nest-building in Sept–Dec and dependent young seen Jan and Nov in Liberia; dependent young in Mar in Bioko, and Mar and Nov in Gabon; in Cameroon, “breeding activity” recorded in Oct, juvenile and one adult in breeding condition in Mar, and adult with brood patch in Nov (also, birds in Mar and Apr in non-breeding condition and without signs of moult). Male aggressively territorial, displays with shrill calls, and pectoral tufts much in evidence, while head and tail projected forwards, wings drooping, tail spread, bill wide open (revealing red-orange mouth). Nests under construction in Liberia located 9–15 m up in outer twigs of understory trees. Young fed by both parents. No other documented information.

Movements. No data; probably sedentary.

Status and Conservation. Not globally threatened. Common in forests in Liberia; locally common elsewhere in range. Occurs in several protected areas, e.g. Korup National Park, in Cameroon.

Bibliography. Bannerman (1948), Borrow & Demey (2001), Bouet (1942), Brosset & Éard (1986), Chapin (1954), Cheke & Mann (2001), Christy & Clarke (1994), Eisentraut (1963), Fry *et al.* (2000), Gatter (1997), Hall & Moreau (1970), Meise (1958), Pérez del Val (1996), Rand *et al.* (1959), Serle (1957), Traylor (1962).

3. Grey-headed Sunbird

Deleornis axillaris

French: Souimanga à tête grise **German:** Graukopf-Nektarvogel **Spanish:** Suimanga Cabecigrís

Taxonomy. *Camaroptera axillaris* Reichenow, 1893, Uvamba, Semliki valley, western Uganda.

Formerly placed in genus *Anthreptes*. Sometimes treated as conspecific with *D. fraseri*, but the two meet in SW DR Congo apparently without intergrading. Monotypic.

Distribution. Congo Basin E to S & E Uganda and extreme NW Tanzania.

Descriptive notes. 11–13 cm; male 11–15 g, female 8.3–13 g. A mostly green sunbird reminiscent of a sylviid warbler, but with long, stout, finely serrated straight bill curved at extreme tip. Male has dark grey head with contrasting paler grey lores, chin and throat; uniformly dull green upperparts, dark brown flight-feathers with bright yellowish-green edges, yellowish-green tail; underparts pale greenish-yellow, flanks dark olive, pectoral tufts bright orange with yellowish at base, axillaries white or with yellow wash; iris variable, from brown or reddish-brown to dull red, orange or sepia; upper mandible black to grey, contrasting pale brown to light grey lower mandible; legs olive-

brown to pale grey, claws yellow. Distinguished from *D. fraseri* mainly by grey head with pale lores to throat. Female is like male but without pectoral tufts, has feet olive-grey, claws and soles greyish. Juvenile has green head with pale yellowish-green supercilium, light brown iris, greenish-olive legs. Voice. Protracted trill of rising and falling notes. **Habitat.** Primary forest, secondary forest and clearings, mainly at 700–1550 m. **Food and Feeding.** Insects, spiders (Araneae) and small fruits. Forages in middle storeys of forest; frequents treetops, creepers on trees and undergrowth at forest edges.

Breeding. Birds in breeding condition in Jul and Oct in DR Congo, in Apr–Aug and Oct–Nov in Uganda and in Nov in Tanzania; fledglings Apr, May and Aug in Uganda. No other information. **Movements.** No information. **Status and Conservation.** Not globally threatened. Common in forests of NE DR Congo; common in forests of Budongo, Kifu and Kasyoha-Kitomi, in Uganda. **Bibliography.** Baker & Baker (2007), Bannerman (1948), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Friedmann (1966), Friedmann & Williams (1970, 1971), Fry *et al.* (2000), Hall & Moreau (1970), Sinclair & Ryan (2003).

Genus *ANTHREPTES* Swainson, 1832

4. Plain-backed Sunbird

Anthreptes reichenowi

French: Souimanga de Reichenow **Spanish:** Suimanga de Reichenow
German: Blaukehl-Nektarvogel
Other common names: Blue-throated (Little)/Plain-backed Little/Gunning's Sunbird, Zambesi Blue-headed Sunbird; Kenya Sunbird (*yokanae*)

Taxonomy. *Anthreptes reichenowi* Gunning, 1909, Mzimbiti, near Beira, Mozambique. Sometimes regarded as forming a superspecies with *A. anchietae*. Two subspecies recognized. **Subspecies and Distribution.** *A. r. yokanae* van Someren, 1921 – SE Kenya (Soko) S in coastal forests to NE & SE Tanzania. *A. r. reichenowi* Gunning, 1909 – NC & E Zimbabwe, SW & SE Mozambique and NE South Africa.

Descriptive notes. 10–11 cm; 5–10 g. Small sunbird, male with iridescent deep blue throat, looking black in field, with short slightly curved bill. Male nominate race has forecrown, throat and upper breast deep blue with brighter iridescent reflections, yellow borders on sides of throat; mid-crown to nape and on cheek and ear-coverts dull greenish-yellow, diffuse yellowish supercilium, hindneck and upperparts, including uppertail-coverts, bright olive-green, flight-feathers and wing-coverts bright olive-yellow with brighter yellow edges, tail light brownish-green with bright olive-yellow edges; lower breast to undertail-coverts lemon-

yellow with wash of bright yellow, lemon-yellow pectoral tufts; iris brown; bill blackish-horn, bluish-grey at base; legs brown or greyish. Female is like male, but lacks blue on head, has throat dull greenish-grey and underparts paler yellow. Juvenile is like female but more olive; immature male as adult female, but throat a mixture of iridescent blue and pale yellow patches, gains iridescence on forehead and more olive on upperparts when older. Race *yokanae* is smaller than nominate (wing 51–56 mm, as against 53–57 mm of nominate), with greener abdomen, paler pectoral tufts and throat of male more blackish, legs blue-grey. Voice. Song of 3–5 notes repeated 4–6 times, descending from beginning to end. Calls “tic-tic”; alarm call of “wee-wee-wee” or similar. **Habitat.** Forest, usually near coast, but occasionally in inland gallery forest within savanna and both brachystegia (*Brachystegia*) and *Brachylaena* woodlands; also gardens.

Food and Feeding. Mostly insects and spiders (Araneae). Probably feeds also on nectar, as visits flowers of mistletoes (Loranthaceae) and species of genera *Albizia*, *Diospyros*, *Kigelia* and *Mimusops*. **Breeding.** Egg-laying Mar–Nov; breeding recorded in Feb, Mar, Jul and Aug in Tanzania. Territorial male sings from high vantage point; in courtship, male chases female until she perches, he then sits above her while singing, flicking wings to expose pectoral tufts, female quivers wings during this performance. Nest an oval pouch 115 mm tall and 65 mm wide, of grass, leaves, twigs and bark, held together with cobwebs, cocoons sometimes added as decoration, entrance near top 35 mm in diameter and with porch of grass, suspended 5 m above ground. Clutch 2–3 eggs, white with dull red spots, mostly towards blunt end; no information on incubation and nestling periods. **Movements.** No data.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Occurs at only a few sites, where not uncommon. Nominative race recorded in coastal and isolated inland forests from Quelimane S to Maputo, in Mozambique, extending W to near Harare, in Zimbabwe, and in extreme NE South Africa; race *yokanae* in coastal forests from Soko, in SE Kenya, S discontinuously to SE Tanzania. Main threat is habitat loss.

Bibliography. Allan & Tree (1997), Anon. (2007f), Baker & Baker (2007), Bulchart & Stattersfield (2004), Cheke & Mann (2001), Evans (1997), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Hall & Moreau (1970), Hipkiss *et al.* (1994), Hockey (1997), Hockey *et al.* (2005), Hustler (1985), Irwin (1995a, 1995b), Jensen *et al.* (2005), Lewis & Pomeroy (1989), Skead (1967), Stattersfield & Capper (2000), Williams (1951c, 1953d).

5. Anchieta's Sunbird

Anthreptes anchietae

French: Souimanga d'Anchieta **Spanish:** Suimanga de Anchieta
German: Buntbauch-Nektarvogel

Other common names: Red-and-blue Sunbird

Taxonomy. *Nectarinia anchietae* Bocage, 1878, Caconda [Huila], Angola. Sometimes regarded as forming a superspecies with *A. reichenowi*, Monotypic. **Distribution.** C & E Angola, SE DR Congo, Zambia (Eastern Province, also W of Luangwa Valley and in Northern Province), and SW Tanzania S to Malawi (W of Rift Valley) and adjacent NW Mozambique.

Descriptive notes. 10–12 cm; 8 g. Both sexes unmistakable: mostly brown above and bright orange-red and yellow below. Male has forehead and crown and chin to upper breast dark iridescent blue, lores metallic blue, face, upperparts, wing feathers and tail brown, tail with hint of gloss, primaries edged buff, obscure orange-yellow patch on wing bend; side of breast bright yellow, central breast to upper belly bright orangey red, rest of underparts greyish-brown except for bright orange-red undertail-coverts and yellow pectoral tufts; axillaries and underwing-coverts buffish-brown; iris dark brown; bill and legs black. Female is similar to

male, but lores brown, blue only on forehead, with chin and throat brown (but having dark iridescent blue tips), breast side duller yellow with olive wash, area of orange red on central belly smaller. Immature is like female, but upperparts paler, short off-white supercilium reaching behind eye, off-white area beneath eye; chin to upper breast brownish-olive, rest of underparts pale olive-yellow. Voice. Song complex, including sounds such as “tseu-werr”, “tsoo-wit”, “tser-wit-tsi-tsi”, “chip-choo-chip”, “witchoo-witchoo”, “chip-chip”, “chip-up-chip-up”, “chip-yoo-chip-yoo”, repeated up to 40 times; also a simpler “twi-tsi-tsi-twi” or up to 20 repeats of ascending “tzer-chip-chip-chip”.

Habitat. Brachystegia (*Brachystegia*) woodland and areas of degraded woodland, where favours rocky zones.

Food and Feeding. Insects and nectar; also fruits. Visits flowers of *Crossopertix*, *Erythrina*, *Faurea saligna*, *Protea*, *Syzgium* and *Tecoma*; takes fruits of *Macaranga asas* and *Ochthocosmus africanus*. Forages in canopy.

Breeding. Breeds in Feb, Aug and Sept in Tanzania, and laying in Sept–Dec in Malawi and Apr–May in Zambia. Domed nest, with side entrance, made of flowers, seeds and twigs bound with leaves, lined with fluff from *Faurea saligna*, suspended up to 6–5 m above ground in bush or tree. Clutch 1–2 eggs, blue-white or grey, spotted black and sepia and with grey scrawls, mostly at larger end; no information on incubation and nestling periods.

Movements. Absent from Zambian sites in rainy season, but no data on distances moved; also, local wandering in Malawi.

Status and Conservation. Not globally threatened. Uncommon or locally common in most of range. Occurs in Kasungu National park, Lilongwe Nature Sanctuary and Dzalanyama Reserve, in Malawi.

Bibliography. Baker & Baker (2007), Benson & Benson (1963), Benson & Irwin (1967), Benson *et al.* (1971), Chapin (1954), Cheke & Mann (2001), Dowsett (1977b), Dowsett-Lemaire (1979), Dowsett-Lemaire & Dowsett (2006), Fry *et al.* (2000), Hall & Moreau (1970).

6. Plain Sunbird

Anthreptes simplex

French: Souimanga modeste **German:** Schlichtnektarvogel **Spanish:** Suimanga Sencillo
Other common names: Plain-coloured Sunbird

Taxonomy. *Nectarinia simplex* S. Müller, 1843, Sumatra and Borneo. Birds from Borneo, having different colour gloss on forehead of male, described as race *simplicior*, possibly worthy of recognition. Proposed races *xanthochlora* (from Tenasserim, in S Myanmar) and *euthapsinus* (Bunguran, in Natuna Is) considered indistinguishable from those elsewhere in range. Treated as monotypic.

Distribution. Extreme S Myanmar (S Tenasserim), SW & S Thailand, Peninsular Malaysia, Sumatra (including Nias I), N Natuna Is and Borneo.

Descriptive notes. 12 cm; male 7–10.7 g, female 7.1–11.8 g. Male has metallic blue or green forehead, and dull green-olive crown to hindneck and upperparts; side of head and throat grey; underparts greyish-olive, becoming yellowish-green on centre of belly and undertail-coverts; iris reddish-brown, bill black; legs brown or greenish. Female differs from male in lacking metallic coloration on forehead. Juvenile is browner above and paler below than female; bill pale yellowish-brown to orange-yellow, legs orange-yellow. Voice. Metallic chips and trills; high-pitched “seep”.

Habitat. Various forest types, including peatswamp, mangroves, at forest edge, and in plantations, scrub, including coastal, secondary growth, cultivation and gardens; sea-level to 1200 m.

Food and Feeding. Insects, including caterpillars; also nectar, fruits and seeds. Nectar includes that of durian trees (*Durio*). Gleans leaves for insects.

Breeding. Laying in Mar in Myanmar, Mar, Apr and Jul in Malay Peninsula, and May–Jun in Sumatra (Kru); fledglings in early Apr and birds with enlarged gonads in Feb, Jun and Aug in N Borneo (Sabah); juveniles in May on Nias I (off Sumatra). Nest an untidy mass of grass and fibres and cobwebs, without porch, lined with thickly felted down, one placed 3–5 m up on *Acacia mangium* on forest track. Clutch 2 eggs, white with mauve-grey suffusion, sparsely blotched, spotted and streaked purple-grey all over; no information on incubation and nestling periods.

Movements. None recorded.

Status and Conservation. Not globally threatened. Very rare in Myanmar; uncommon in Thailand and Peninsular Malaysia; locally common in Sumatra and Borneo. Occurs in Taman Negara National Park, in Peninsular Malaysia; Way Kambas National Park, in Sumatra; and several protected areas in Borneo including Gunung Mulu National Park and Danum Valley Conservation Area.

Bibliography. Cheke & Mann (2001), Dymond (1994), Ford (1995), Holmes (1996), Lambert (1991), MacKinnon & Philipps (1993), Mann (1996, 2008), van Marle & Voous (1988), Medway & Wells (1976), Oates (1989a), Robson (2000b), Sheldon *et al.* (2001), Smythies (1986), Thompson (1966), Wells (2007), Yumoto (2000).

7. Brown-throated Sunbird

Anthreptes malacensis

French: Souimanga à gorge brune **Spanish:** Suimanga Gorjipardo
German: Braunkehl-Nektarvogel
Other common names: Plain-throated/Lesser Sunda Sunbird ("chlorigaster group")

Taxonomy. *Certhia malacensis* Scopoli, 1786, Malacca, Peninsular Malaysia.

Forms a superspecies with *A. griseigularis* and often treated as conspecific, but the two exhibit constant differences in plumage and measurements, and no indication of hybridization or introgression; close also to *A. rhodolaemus*. Races form two groups: "*chlorigaster* group" (incorporating also *heliolusius* and *wiglesworthi*), males of which have head and back iridescent dark green and underparts generally olive-green, and "nominate group" (all other races), males having head to rump iridescent violet and underparts bright yellow. Geographical variation otherwise not well marked; races *anambae*, *erixanthus* and *bornensis* possibly better merged with nominate, in which *paraguae* and *mjobergi* were formerly included; *heliolusius* has in the past been synonymized with *chlorigaster*. In addition, population on Lombok (W Lesser Sunda) of uncertain racial affiliation, belongs either with nominate race or with *convergens*; further study required. Birds from Marinduque and Camiguin Sur (C & S Philippines) reported to represent two further races, but to date no descriptions formally published. Other proposed races are, off W Sumatra, *pellipitulus* (from Simeulue I), *pollostus* (Mt Lembu, on Nias I) and *nesaeus* (Pagai Is), all included in nominate, as also are *javanicus* (Java) and *baweanus* (Bawean I, N of Java); *basilanicus* (Basilan, in S Philippines), included in *heliolusius*; *sanghiranus* (Sangihe I, N of Sulawesi), merged with *heliolusius*; and *nesophilus* (Mantehage, off NE Sulawesi) and *citrinus* (described from Wawo, in SE Sulawesi), both synonymized with *celebensis*. Sixteen subspecies currently recognized.

Subspecies and Distribution.

A. m. malacensis (Scopoli, 1786) – SW & S Myanmar, Thailand, Indochina, Peninsular Malaysia and nearby islands, Sumatra and satellites, most of Borneo (Sarawak and Kalimantan), Karimata I (off SW Borneo), Java (including Madura) and Bali.
A. m. anambae Oberholser, 1917 – Anamba Is (E of Peninsular Malaysia).
A. m. erixanthus Oberholser, 1932 – Natuna Is.
A. m. bornensis Riley, 1920 – N Borneo (Sabah and Brunei).
A. m. paraguae Riley, 1920 – Calamian Group (Calauit, Culion), Palawan and Balabac, in W Philippine Is.
A. m. cagayanensis Mearns, 1905 – Cagayan Sulu (S of Palawan).
A. m. chlorigaster Sharpe, 1877 – C Philippines (Lubang, Tablas, Sibuyan, Masbate, Panay, Negros, Cebu, probably also Romblon and Ticao).
A. m. heliolusius Oberholser, 1923 – Basilan and W & C Mindanao (including Talicud), in S Philippines.
A. m. wiglesworthi E. J. O. Hartert, 1902 – Sulu Archipelago (Basbas, Jolo, Tawi-tawi, Sanga-Sanga, Bongao, Simunul, probably also Pangamian).
A. m. iris Parkes, 1971 – SW Sulu Is (Tumindao, Sibutu, probably also Sitanki), in far SW Philippines.
A. m. mjobergi Bangs & Peters, 1927 – Maratua I, off E Borneo
A. m. heliocalus Oberholser, 1923 – Sangihe and Siau, N of Sulawesi.
A. m. celebensis Shelley, 1878 – Sulawesi, including Mantehage, Manadotua, Manterawu, Talisei, Bangka, Togian Is, Labuan Blanda, Kabaena, Muna and Butung.
A. m. extremus Mees, 1966 – Banggai Is and Sula Archipelago.
A. m. convergens Rensch, 1929 – Lesser Sunda (Sumbawa, Komodo, Padar, Flores, Adonara, Satonda, Lomblen, Pantar, Alor).
A. m. rubrigena Rensch, 1931 – Sumba (in SW Lesser Sunda).
Also present on Marinduque and Camiguin Sur (C & S Philippines), possibly representing two further races.

Descriptive notes. 12.1–13.5 cm; male 11.1–13.5 g, female 7.4–13.1 g. Male nominate race is oily metallic purple-green above, with purple or violet back, rump, uppertail-coverts and shoulder; rufous-olive or chestnut on upperwing-coverts and scapulars, brown remiges edged warm olive to greenish-yellow; blackish-brown tail edged glossy blue-green; side of head olive-green to greenish-brown; chin and throat pale pinkish-brown with lateral border of metallic purple, pale pinkish-red on lower forehead; pectoral tufts bright yellow, rest of underparts greenish-yellow, brighter on breast and upper belly; iris red; bill black; legs

grey or olive-brown. Female is greyish olive-green above, with nares, eyering and moustachial stripe yellowish, wing and tail brown, edged greenish-yellow, throat and underparts bright greenish-yellow. Juvenile is similar to female, but has paler bill. Races differ mainly in plumage tone and in colour of iridescence in male plumage: *anambae* male has paler throat, is richer yellow below than nominate; *mjobergi* male differs from nominate in having cheeks concolorous with throat; *bornensis* is smaller than previous, and female is duller below; *erixanthus* is larger than previous, with paler yellow posterior underparts and greyer flanks and crissum in male, paler and yellower above in female, with yellower throat, darker rest of underparts, and medially more golden-yellow; *paraguae* male differs from nominate in having purple-green on head and back, wing edges greenish or slightly orange, lores and postorbital patch greenish-brown (sometimes tinged orange), chin and throat dull reddish, belly duller yellow; *cagayanensis* male has less rufous on greater coverts than previous, and has some green iridescence from head to lower back, which is lacking in *paraguae*; *iris* male has green and purple iridescence of head to back well demarcated from entirely purple rump, rusty only on edges of greater coverts, some orange in pectoral tufts; *celebensis* male has pinkish-brown to dull chestnut on wing-coverts, is rather dull and greenish below, female pale greyish-yellow below; *extremus* is larger, with larger, broader and stronger bill, and male is greener and less yellow below, greyer on throat and generally duller than last; *heliocalus* male is bigger and longer-winged than preceding two races, and male brighter and more yellow below; *convergens* male is more greenish-yellow below than nominate, has greenish-brown edging on remiges; *rubrigena* male differs from last in lack of chestnut on scapulars and greater wing-coverts, has only edges of wing-coverts vivid matt red-brown, is less pure yellow than nominate (but less olive than *celebensis*), and female is greyer on head than any of these other races; *chlorigaster* male has head and back iridescent bottle-green, rump violet, chin and throat more reddish-brown, female tends to be more yellow on breast and belly than those of "nominate group"; *heliolusius* male differs from previous in having olive-brown cheek, paler red wing-coverts and edgings, and is generally brighter; *wiglesworthi* male differs from last in brighter yellow underparts, redder cheek, paler and brighter edges of remiges, female has reddish wash on wing-coverts and edgings. Forms not yet formally

described: in Marinduque birds, male is washed yellow below, has brighter olive-green breast, belly and flanks than *chlorigaster*, remiges lighter brown with brighter olive edgings, brighter dark olive cheek, throat peach-coloured, female generally more grey above and below than other races and less bright than *chlorigaster* (cheek and throat olive-grey, breast, belly and flanks olive-grey with yellow wash); Camiguin Sur birds are larger than *heliolusius* in wing, bill and tail measurements, male differs from that race in having no purple sheen from head to back, darker olive on cheek, lighter brown remiges edged bright olive-yellow, greater and median wing-coverts light rusty, throat lighter red, breast to belly bright olive-green with yellow wash, some orange in pectoral tufts, female has crown to back greener, rump and tail edged bright rusty, edges of remiges bright olive-yellow, throat lightly washed yellow (as opposed to buffy grey), and breast to belly duller and less yellow. **Voice.** Song, from prominent perch, of 2–4 notes, "sweet-sweet", or "sweet-sweet-sweet", or "wee-chew-chew-wee". Calls include much-repeated piercing double note, first rising, second falling, also loud cheerful "kelichap" singly or as random pitch-change sequence; hard "swit", thin drawn-out high-pitched "siuewei", shrill "whiuu" during foraging; soft "twit-twit" in flight, louder and harder "chit-chit-chit" during pursuit-flights; also rapid nasal "tititili" chatter and repeated melodious "wee-chuuw".

Habitat. Various types of forest, but generally not in interior; habitats include mangroves, plantations, scrub, swamp, cultivation, coconut groves, secondary growth and gardens. Sea-level to 1200 m.

Food and Feeding. Insects, including caterpillars, also spiders (Araneae); also fruits, including mistletoes (Loranthaceae), and seeds of *Dillenia suffruticosa*; also nectar of mistletoes and *Hibiscus*, and of the mangroves *Bruguiera* and *Xylocarpus granatum*. Forages singly and in pairs, often in canopy but also at all other levels. Gleans leaves and twigs, and visits spider webs. Often chases other birds away from flowers.

Breeding. Laying Feb–Jul and Sept in Thailand, and Jun in Sumatra; laying Dec/Jan–Aug, fledglings in May, in Peninsular Malaysia; may breed all year in Borneo, where recorded Jan–Mar, May and Jul in N (Sabah) and May and Jul in S (also, active gonads Jan–Mar and Jun–Aug and family parties Apr–Jul in N, juveniles Jul and Aug in S); eggs in all months except Oct in Java; Mar–Nov in Sulawesi, Apr–Aug in Lesser Sunda (Flores); birds with active gonads possibly in Apr and fledged young in at least Jul in Philippines; may be at least double-brooded in Malay Peninsula. Nest a neat, globular to pear-shaped structure, entrance with eave one-third from top, made of grass, plant fibres and twigs, decorated with silk cocoons, *Casuarina* needles, slivers of bark and cobwebs, with or without short dangling "tail", lined with tree cotton, *Imperata* pappus and moss, suspended from leafy twig 1–1.3 m above ground. Clutch 2–3 eggs, shape variable (from slightly pointed oval to considerably elongated to slightly pyriform), matt or slightly glossed, white or creamy white with grey, pale purplish-brown or purplish-black clouds, speckled and blotched dark purplish-brown with black scribbling, particularly at broad end, or dull pink with thick grey scribbling, spotted with black and russet; no information on incubation and nestling periods. Nests parasitized by Violet Cuckoo (*Chrysococcyx xanthorhynchus*) in Malay Peninsula.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Common in Thailand, Peninsular Malaysia, Greater Sunda, Philippines, Sulawesi and Sangihe I; scarce to locally common or fairly common in Lesser Sunda. In Philippines, possibly extinct on Cebu (race *chlorigaster*). Acts as pollinator of the mangrove *Bruguiera*.

Bibliography. Adhikerana (1994), Bishop (1992), Blasius (1897), Brooks *et al.* (1995), Brown (2003), Bruce (1987), Cheke & Mann (2001), Classen (1987), Coates & Bishop (1997), Delacour & Mayr (1946), Dickinson *et al.* (1991), Eck (1976), Glenister (1951), Hellebrekers & Hoogerwerf (1967), Holmes & Wood (1980), Hoogerwerf (1949, 1950, 1966), Jones *et al.* (1994), Kennedy *et al.* (2000), Kondo *et al.* (1991), MacKinnon & Phillips (1993), Mann (1996), van Marle & Voous (1988), Mayr (1944a), McGregor (1905a, 1909), Mearns (1905, 1909), Medway & Wells (1976), Mees (1966, 2006), Nash & Nash (1988), Noske (1993), Parkes (1971), Rand (1970), Rensch (1929, 1931a, 1931b), Riley (1997), Robson (2000b), Salomonsen (1953b), Sheldon *et al.* (2001), Smythies (1986), Watling (1983), Wells (2007), White & Bruce (1986), Zimmer (1918).

8. Grey-throated Sunbird

Anthreptes griseigularis

French: Souimanga à gorge grise **German:** Graukehl-Nektarvogel **Spanish:** Suimanga Gorjigris
Other common names: Plain-throated Sunbird

Taxonomy. *Anthothreptes griseigularis* Tweeddale, 1878, Surigao, north-east Mindanao, Philippines.

Forms a superspecies with *A. malacensis* and often treated as conspecific, but the two exhibit constant differences in plumage and measurements, and no indication of hybridization or introgression; close also to *A. rhodolaemus*. Two subspecies recognized.

Subspecies and Distribution.

A. g. birgatae Salomonsen, 1953 – N & C Luzon (including Palaui, off N coast) and Catanduanes, possibly also Polillo Is and Mindoro, in N Philippines.
A. g. griseigularis (Tweeddale, 1878) – Samar, Leyte, Dinagat, Sakujok, Siargao, Bucas Grande and NE Mindanao (Mt Hilong-Hilong S to Mt Mayo), possibly also Bohol, in SE Philippines.

Descriptive notes. 12–13 cm. Male nominate race has forehead to back metallic green, rump and uppertail-coverts metallic purplish-blue; shows much maroon to brick-red on median upperwing-coverts; some metallic violet-blue on carpal-coverts and tips of median coverts; lesser wing-coverts metallic purplish-blue; lores, cheek, ear-coverts, greater wing-coverts and scapulars maroon to brick-red (birds from Samar, Dinagat and Bucas Grande have more red on cheek than do those from Mindanao); flight-feathers dark brown, primaries with pale fringes, secondaries edged maroon; rectrices black, tinged metallic green and violet-blue;

chin and throat grey, violet-tinged metallic green streak from bill along side of neck; breast, flanks, abdomen and undertail-coverts olive-yellow, pectoral tufts bright yellow; underwing-coverts pale yellowish white; iris bright red; bill black; legs greenish-grey. Female has head to upper back, cheek, ear-coverts and lesser wing-coverts dark olive-grey to brown, edged grey, with some feathers slightly tinged green, lower back to uppertail-coverts greyish-green, some feathers of last tinged rusty; primaries dark brown, edged pale rufous, secondaries dark brown, edged dull rusty, greater coverts and scapulars dull rusty, rectrices dark brown, edged dull grey; chin and throat greyish-white, upper breast grey, lower breast to undertail-coverts pale greenish-yellow, underwing-coverts pale yellowish-white; iris dark brown, bill dark brown, lower mandible sometimes lighter brown, legs greenish. Juvenile apparently undescribed, presumably resembles female. Race *birgatae*

is larger, particularly in bill length, than nominate, and male's underparts are duller and darker. Voice. No specific information.

Habitat. Various types of forest, including mangroves, plantations, scrub, swamp, cultivation, coconut groves, secondary growth and gardens, particularly near coast; sea-level to 610 m.

Food and Feeding. Presumably eats invertebrates, fruits and nectar. Information uncertain and requires revision; previously treated as conspecific with *A. malacensis*, and the two not differentiated with regard to details of ecology and biology.

Breeding. No specific information; previously treated as conspecific with *A. malacensis*, and the two not differentiated with regard to details of ecology and biology; revision of data required.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Common. On Luzon, present in provinces of Abra, Bataan, Benguet, Laguna and Isabela. Fieldwork required in order to establish whether this species occurs on Polillo Is. Mindoro and Bohol.

Bibliography. Brooks *et al.* (1995), Brown (2003), Cheke & Mann (2001), Delacour & Mayr (1946), Dickinson *et al.* (1991), Dutton *et al.* (1992), Kennedy *et al.* (2000), Manuel (1937), McGregor (1905a, 1909), Mearns (1905), Parkes (1971), Rabor (1938), Rand (1970), Rand & Rabor (1960), Salomonsen (1953b).

9. Red-throated Sunbird

Anthreptes rhodolaemus

French: Souimanga à gorge rouge

Spanish: Suimanga Gorjirrojo

German: Rotkehl-Nektarvogel

Other common names: Shelley's/Red-shouldered/Rufous-throated Sunbird

Taxonomy. *Anthreptes rhodolaema* [sic] Shelley, 1878, Malacca, Peninsular Malaysia.

Close to *A. malacensis* and *A. griseigularis*. Proposed race *aeneus*, described from E Borneo (Labuan Klambu, in Kalimantan), considered indistinguishable from birds in rest of range. Monotypic.

Distribution. Patchily, from extreme S Myanmar (S Tenasserim) and S peninsular Thailand to Peninsular Malaysia, Sumatra and Borneo.

Descriptive notes. 12 cm; male 11–2 g, female 11–6 g. Male has crown to mantle dark metallic green, maroon band across upper back, rest of back, rump and uppertail-coverts violet; upperwing brown, greater wing-coverts edged rufous, remiges edged bright olive; tail blackish-brown, glossed green; side of face maroon, sometimes browner, especially on ear-coverts; stripe from bill along side of neck, also shoulder, glossed violet; throat pale pink, side of throat and narrow band on upper breast dull red, rest of underparts yellowish-olive; iris red; bill black; legs olive. Female has dull olive crown and upperparts, yellow eyering and

stripe behind eye, olive-yellow below, brighter on lower breast and belly. Juvenile is similar to female, but greyer below, with yellow only on centre of throat to belly. Voice. Various chirps and metallic trills: song a high "sit-sit-sit-see" or slurred "sit-sit-sit-swe-er"; "uu-is" or "tsuu-i", upwardly inflected.

Habitat. Various forest types, including peat-swamp-forest, secondary growth, plantations, clearings and coastal vegetation; sea-level to 900 m.

Food and Feeding. Feeds on insects, including caterpillars, also spiders (Araneae); also pollen, nectar and small fruits, including figs (*Ficus*). Usually in canopy, but occasionally in lower storeys. Gleans foliage.

Breeding. Eggs in late Apr and fledglings mid-Aug in Malay Peninsula; in Borneo, birds with active gonads in Jun–Sept and fledgling in Aug in N (Sabah) and nest-building in Jun in S. Nest constructed of matted plant fibres, with dangling "tail", entrance beneath large eave in upper half, lined with dead leaves, exterior decorated with lichen-covered bark, suspended 9–20 m above ground on cord from tree at edge of clearing. Clutch 1 egg, pale lavender-purple, spotted, blotched and lined dark brown; no information on incubation and nestling periods.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon in Myanmar and Malay Peninsula; rare in Sumatra; very uncommon in Borneo. Possible occurrence on Palawan, in W Philippines, requires investigation. Destruction of lowland forest puts this species potentially at risk; owing to its ability to utilize secondary and submontane forests and forest edge, however, it is not immediately threatened. Occurs in several protected areas, e.g. Taman Negara National Park, in Peninsular Malaysia, and Danum Valley Conservation Area, in Borneo.

Bibliography. Anon. (2007), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar *et al.* (2001), David & Gosselin (2002b), Dickinson *et al.* (1991), Holmes (1996), Kleefisch (1975), MacKinnon & Phillips (1993), Mann (2008), Medway & Wells (1976), Nash & Nash (1988), Pfeiffer (1961), duPont (1971b), Riley (1934), Robson (2000b, 2005a, 2007), Sheldon *et al.* (2001), Smythies (1986), Stattersfield & Capper (2000), Wells (2007).

10. Mouse-brown Sunbird

Anthreptes gabonicus

French: Souimanga brun

German: Gabunnektarvogel

Spanish: Suimanga Pardo

Other common names: Brown/Mouse-coloured/Mangrove Sunbird

Taxonomy. *Nectarinia gabonica* Hartlaub, 1861, Gabon.

Monotypic.

Distribution. Senegambia E. discontinuously, to Nigeria and W Cameroon. S to Angola (Cabinda and mouth of R Kissama).

Descriptive notes. 10 cm. Dull sunbird, lacking metallic colours; bill broad at base, only slightly decurved. Male is mouse-brown above, with narrow white line across forehead, and white extending from lores to above and below eye (where conspicuous); hint of olive-green on outer half of uppertail-coverts and outer webs of flight-feathers, small white carpal patch; tail dark brown, broad white tips and greenish fringe on outer webs of all except central pair of feathers, outer edges of tips of outermost pair white on both surfaces; greyish-white below, white underwing-coverts and axillaries; iris red or brown; bill black; legs

black, toes sometimes paler, more greyish. Distinguished from female of *A. longuemarei* by white around eye and grey underparts; from female of *Cyanomitra cyanoalaema* (which also has white around eye) by shorter and straighter bill. Female is very like male, but has less prominent green on outer webs of remiges and rectrices. Juvenile is also similar, but more olive on wings and upper body, with lemon-yellow tinge below. Voice. Song consists of sequence of twitters, e.g. "tser-tser-tsew-tsi-tsi-tsi-tsi-tsi-tseuuur". Calls are quiet "tserr", "wit-wit-sqee-witter-witter" or "tsurp-tseep-tseep" or just "tseep" or "sqee", occasionally repeated.

Habitat. Coconut plantations, mangroves, farmland and gardens in coastal zones; also strays inland along riverine forest beside large rivers, e.g. reaches Madina-Diassa, in S Mali.

Food and Feeding. Few data. Hunts insects in trees and lianas, often close to water, using behaviour like that of a sylviid warbler. Common visitor to *Hibiscus* flowers in coastal gardens of S Cameroon, but not certain whether nectar or insects were taken.

Breeding. Egg-laying recorded in all months in W Africa, Apr and Jun in Gabon and Sept in DR Congo. Territorial. Nest (without hanging "beard") made of grass, dead leaves and spider webs, lined with feathers, grass and pappus, suspended usually over water at riverside or in mangroves. Clutch 1–2 eggs, grey, faintly washed violet, with dark streaks and spots; incubation by female; no information on duration of incubation and nestling periods.

Movements. Occurrences beside rivers far inland in wet season suggest seasonal movements.

Status and Conservation. Not globally threatened. Sometimes abundant and usually not uncommon in mangroves; rarer inland. Susceptible to destruction of mangrove habitats.

Bibliography. Bannerman (1948), Borrow & Demeijer (2001), Chapin (1954), Cheke (1999), Cheke & Mann (2001), Christy & Clarke (1994), Dowsett & Dowsett-Lemaire (2005a, 2005b), Fry *et al.* (2000), Gatter (1997), Hall & Moreau (1970), Rand *et al.* (1959), Serle (1949, 1957), Sinclair *et al.* (2004), Walsh (1967).

PLATE 9

11. Western Violet-backed Sunbird

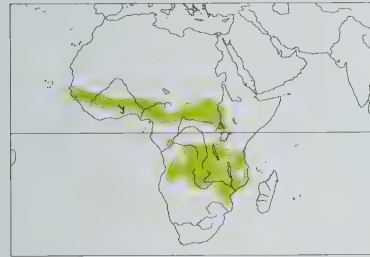

Anthreptes longuemarei

French: Souimanga violet **German:** Violettmantel-Nektarvogel **Spanish:** Suimanga Violeta
Other common names: (African) Violet-backed/Blue/Plum-coloured/Longuemare's Sunbird; Uganda Violet-backed Sunbird (*haussarum*)

Taxonomy. *Cinnyris longuemarei* Lesson, 1833, "Senegambia superior" = Senegal. Forms a superspecies with *A. orientalis*, *A. neglectus* and *A. aurantius*. Race *haussarum* sometimes included within nominate. Four subspecies recognized.

Subspecies and Distribution.

A. l. longuemarei (Lesson, 1833) – Senegal S to Guinea-Bissau and E to N Sierra Leone.
A. l. haussarum Neumann, 1906 – E Guinea E to N Cameroon, Central African Republic, S Sudan, N DR Congo and N & W Uganda.
A. l. angolensis Neumann, 1906 – S PR Congo, SW & SE DR Congo, Angola, Zambia, Malawi W of Rift Valley, and SW Tanzania.
A. l. nyassae Neumann, 1906 – SE Tanzania (S from Dar es Salaam), Malawi E of Rift Valley, N Mozambique and E Zimbabwe.

Descriptive notes. 13–14 cm; 9.8–14 g. Distinctive sunbird with almost straight, stout bill. Male nominate race has metallic violet head, throat and upperparts, bluer on rump; upperwing dark brown, lesser wing-coverts metallic violet with trace of green (sometimes none) at edges; tail blackish, washed metallic violet; underparts white, pectoral tufts yellow; iris dark brown; upper mandible greenish-black, lower mandible greenish-brown; legs dark olive-green. Distinguished from *A. orientalis* mainly by violet (not blue-green) back and rump. Female differs from male in having forehead and upperparts brown apart from metallic

violet uppertail-coverts, distinctive white eyebrow, brown tail washed with metallic violet, yellow belly, no pectoral tufts, white underwing tinged yellow. Juvenile male lacks pectoral tufts, is olive-green above, but uppertail-coverts metallic violet, slight white eyebrow, yellow breast and belly (becoming white on older birds). Race *haussarum* differs from nominate in having metallic green ends of lesser coverts and edges of wing feathers; *angolensis* male has lesser coverts metallic green, breast washed buff, female has chin to breast off-white softly streaked grey, juvenile remiges edged yellow-green; *nyassae* male is more violet above than preceding race, lacking greenish tinge, underparts white, female darker brown above, crown with violet gloss, underparts less yellow than previous. **VOICE.** Song (race *angolensis*) a rapid series of five or six rising and falling chatters before ending with "zit-zit-zit-chit-chit". Call "chip-chip" or "cha-cha-cha" or "t-claa-tee-tee"; alarm call "skee" or sharp "tit".

Habitat. Savanna woodland, including acacia (*Acacia*), miombo and *Uapaca* woodlands, gallery forest in savanna, also gardens, lakeside scrubland and mangroves.

Food and Feeding. Insects, including beetles (Coleoptera), flies (Diptera), lepidopteran larvae and Hymenoptera; spiders (Araneae). Also nectar from mistletoes (Loranthaceae), aloes (*Aloe*), proteas (*Protea*), baobabs (*Adansonia*) and other trees such as *Bauhinia*, *Bombax*, *Brachystegia*, *Erythrina*, *Faurea speciosa*, *Parinari macrophylla*, *Spathodea* and *Syzgium guineense*. Forages in manner of Old World warbler (Sylviidae), but also seeks food in bark; also hawks for insects.

Breeding. Egg-laying in Feb–May and Nov in W Africa, mostly Jan–Mar in E Africa; Feb and Sept–Dec in DR Congo, Feb, Jul, Sept, Oct and Dec in Zambia; Jun, Aug, Sept and Dec in Tanzania (breeding activity also Jan, May, Jun), Sept–Nov in Malawi and Aug–Dec in Zimbabwe. Male strongly territorial. Nest, built by female, an untidy structure with side entrance near top, made of dead leaves, bark, grass and spider webs, lined with vegetable down, attached 4–7.5 m above ground in tree. Clutch 1–2 eggs, greenish-white or blue-white or pale buff, with brown or black scribbles concentrated at wider end; incubation by female alone, but chicks fed by both sexes; no information on duration of incubation and nestling periods; both parents feed young out of nest, both also roost with young side by side.

Movements. In W Africa moves N in Jan–May, to breed in N savanna in dry season. Probably sedentary in Uganda and Zimbabwe apart from local wanderings in dry season and juvenile dispersal. Scarce non-breeding migrant in Kenya; local wanderer in Malawi.

Status and Conservation. Not globally threatened. Uncommon in W Africa; common in S Sudan and savannas of DR Congo; not uncommon in Uganda W of Budongo Forest; scarce in S Africa, uncommon in Malawi and Zambia, less so in miombo woodland of Angola. Occurs in several protected areas, e.g. Maraoué National Park, in Ivory Coast, Bénoué National Park, in Cameroon, and Dzalanyama Reserve and Lilongwe Nature Sanctuary, in Malawi.

Bibliography. Baker & Baker (2007), Bannerman (1948), Barlow *et al.* (1997), Borrow & Demey (2001), Britton (1981), Carroll (1988), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire & Dowsett (2006), Fry *et al.* (2000), Hall & Moreau (1970), Hockey *et al.* (2005), Krienke (1941), Lynes (1938), Medland (1991), Newby-Varty (1945), Pettet (1977), Priest (1938), Serle (1957), Shead (1967), Tree (1997k), Walsh (1966), Walsh *et al.* (1990), Wells (1966), White (1963).

12. Kenya Violet-backed Sunbird

Anthreptes orientalis

French: Souimanga du Kenya **German:** Schwalbennektarvogel **Spanish:** Suimanga Keniata
Other common names: Eastern Violet-backed Sunbird, Kenya Sunbird

Taxonomy. *Anthreptes orientalis* Hartlaub, 1880, Lado, on Bahr-el-Jebel (White Nile), Sudan. Forms a superspecies with *A. longuemarei*, *A. neglectus* and *A. aurantius*. Two proposed races, *neumannii* (described from Afgoi, in S Somalia) and *barbouri* (from Dodoma, in Tanzania), are both considered insufficiently differentiated from birds elsewhere in range. Monotypic.

Distribution. SE Sudan, Ethiopia and NW & S Somalia S to N Uganda, Kenya and NE & WC Tanzania, also Rwanda,

rump; from *A. neglectus* mainly in white (not grey-brown) underparts. Female is greyish-brown above except for whitish supercilium, violet-blue uppertail-coverts and tail, outer web of outermost rectrix brown, dull white below, belly and flanks yellowish, lacks pectoral tufts. Juvenile is similar to female, apart from buff or yellow on middle of belly and brownish crown, mantle and wing-coverts. **VOICE.** Song a brief series of rising and falling twitters, "too-wit-woo-tweu, zeet-zeet"; call 1 or 2 "chwee" notes.

Habitat. Woodland, including junipers (*Juniperus*) in highlands, and dry bush country. Prefers drier country than that inhabited by *A. longuemarei*.

Food and Feeding. Insects and spiders (Araneae); nectar. Searches among foliage and bark in manner of Old World warbler (Sylviidae). Visits *Leonotis* flowers and mistletoes (Loranthaceae). Hawks for insects.

Breeding. Egg-laying in Nov–Mar in Sudan and Apr–Jun Ethiopia; recorded in all months except Mar and Sept in E Africa. Territorial. Nest oval, with short porch above entrance, made of grass, wool, hair and pappus, adorned with old egg capsules of mantises (Mantodea), attached low in bush. Clutch 1–2 eggs, green-grey, speckled with dark grey, brown or black; no information on incubation and nestling periods.

Movements. No data.

Status and Conservation. Not globally threatened. Common in Sudan, Ethiopia, Somalia and Uganda; uncommon in Kenya. Occurs in several protected areas, e.g. Awash National Park, in Ethiopia, and Tarangire National Park, in Tanzania.

Bibliography. Ash & Miskell (1983), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Friedmann (1931, 1937), Fry *et al.* (2000), Hall & Moreau (1970), Kahindi & Kageci (1995), Lewis & Pomeroy (1989), Prinzing & Jackel (1986), Prinzing *et al.* (1989), van Someren (1922), Zimmerman *et al.* (1996).

13. Uluguru Violet-backed Sunbird

Anthreptes neglectus

French: Souimanga des Uluguru **Spanish:** Suimanga de las Uluguru
German: Ulugurunektarvogel
Other common names: Uluguru Sunbird

Taxonomy. *Anthreptes longuemarei neglectus* Neumann, 1922, Uluguru Mountains, Tanzania.

Forms a superspecies with *A. longuemarei*, *A. orientalis* and *A. aurantius*. Monotypic.

Distribution. SE Kenya, mountains of E Tanzania and NE Mozambique.

Descriptive notes. 12 cm; 12.8–15.5 g. Smallish sunbird with violet back in both sexes. Male has reddish-violet forehead, crown, mantle, back and scapulars, dull black nape, metallic blue-green rump, metallic violet uppertail-coverts; upperwing dark brown, edged greenish-olive to mustard yellow, iridescent green shoulder and median wing-coverts, greater wing-coverts edged green to yellow; uppertail metallic violet (black below), tips of outer feathers white; chin and upper throat metallic reddish-violet, lower throat, underparts and underwing whitish, pectoral tufts yellow or orange, buff wash on belly, flanks and undertail-coverts; iris dark brown; bill black; legs greyish. Distinguishable, with care, from *A. orientalis* and *A. longuemarei* by broader yellow-green edges to remiges and upperwing-coverts, dark brown hindcollar; female and immature dimmer buffy-grey (not white) below than those species. Female is similar to male, but central part of forehead blackish-brown, chin and throat white, and has much yellow on belly, undertail-coverts and thighs, rest of underparts buffy-grey with diffuse darker streaking, and olive streaks at side of belly; probably lacks pectoral tufts (but two examined specimens labelled as females had yellow tufts). Juvenile has distinct white supercilium, dull brown crown, mantle and wing-coverts, occasionally with metallic violet wash but iridescence may be only on uppertail-coverts, tail and bend of wing; remiges edged yellow-green; lemon-yellow on lower belly and vent. **VOICE.** Call "tsssp" or "sweep-sweep-sweep" repeated up to four times, sometimes preceding a melodious trill.

Habitat. Montane and submontane forest at up to 1800 m; gallery forest, thickets and tea plantations at forest edge; moist scrubland, wooded country and forests along Kenyan and Tanzanian coasts.

Food and Feeding. Few data. Visits *Grevillea* and mistletoes (Loranthaceae), and takes insects. Forages in groups of up to 6 birds.

Breeding. Egg-laying in Dec, Jan and Mar in E Africa; Dec–Feb and Sept, and active nests recorded Sept–Dec, in Tanzania. Territorial. Untidy nest with dangling "beard", constructed from grass, lichens and moss, lined with white vegetable down, suspended 8 m up from tree. Eggs evidently undescribed; male feeds fledglings.

Movements. Presumed resident.

Status and Conservation. Not globally threatened. Scarce in most of range; locally common in E Usambaras and Uluguru Mts (Tanzania). Occurs at comparatively few sites: in Kenya found in Shimba Hills, R Tana forest, Buda Forest Reserve and Jadini forest; in Tanzania present in Ulugurus,

Ukagurus and Udzungwas, N Nguu Mts, W Usambaras, and Mt Nilo (in E Usambaras); and in Mozambique occurs at River Lurio and Netia.

Bibliography. Alexander (1995a), Baker & Baker (2007), Borghesio *et al.* (2008), Britton (1981), Butynski (1994), Cheke & Mann (2001), Evans, T.D. (1996), Fjeldså *et al.* (1997), Fry *et al.* (2000), Hall & Moreau (1970), Hipkiss *et al.* (1994), Jensen *et al.* (2005), Keiith (1968), Lewis & Pomeroy (1989), Sclater & Moreau (1933), Seddon *et al.* (1999a, 1999b), Stuart & Jensen (1985), Zimmerman *et al.* (1996).

14. Violet-tailed Sunbird

Anthreptes aurantius

French: Souimanga à queue violette **Spanish:** Suimanga Colivioleta
German: Violettschwanz-Nektarvogel

Taxonomy. *Anthreptes aurantium* J. Verreaux and É. Verreaux, 1851, Gabon. Forms a superspecies with *A. longuemarei*, *A. orientalis* and *A. neglectus*. Males from Gabon and lower R Congo have buff breast and more violet on throat than those from E DR Congo (Ituri Mts), and some adult females have white (not yellow) belly, but it is unclear whether recognition of geographical races is warranted. In original description, species name clearly appears to be adjectival, and gender must be corrected. Monotypic.

Distribution. S Cameroon, S Central African Republic, Gabon and PRCongo E to W & N DR Congo (E to Ituri Forest); also NE Angola.

Descriptive notes. 13–14 cm; 12–13 g. Smallish sunbird with long, slightly curved bill. Male has crown to mantle brilliant metallic blue or green (depending on reflections), back greenish, rump and uppertail-coverts blue; remiges brown, secondaries and upperwing-coverts with wide metallic green edges; tail violet or blue, edged green; side of head blackish, slightly glossy, throat metallic green; pectoral tufts orange, underparts and underwing pale buff, belly more grey, sometimes white; iris dark brown; bill black, base of lower mandible grey; legs black, tinged bluish or greyish. Distinguished from *A. longuemarei* by orange (not yellow)

pectoral tufts and green or blue (not violet) upperparts. Female is like male but bluer, less purple, above, with distinct white or dull yellow supercilium, dark line through eye, throat greyish-white, underparts pale yellow, pectoral tufts yellow with slight orange wash. Juvenile is grey-green or greenish-brown above, tail blue with metallic green wash, white wing edges, underside greyish-white with yellow or greenish wash, except on throat. **VOICE.** Little known. High-pitched flight call. **Habitat.** Forest, particularly secondary forest, gallery forest, seasonally flooded forest and swamp-forest, invariably in close proximity to water; also wooded savanna, edges of salt pans and mangroves. **Food and Feeding.** Takes fruits (e.g. of *Macaranga assas*), berries; also insects, such as flying ants (Formicidae), termites (Isoptera), crickets (Orthoptera) and caterpillars; also spiders (Araneae). Female seen to feed small fruits to nestlings. Forages low down, in pairs or in groups of up to four individuals. Probes bases of flowers of *Globimetula* species.

Breeding. Egg-laying in Mar in Cameroon; Apr, Nov and Dec in Gabon; and Apr and Jun (and probably Jul and Sept) in DR Congo; young in nest, Dec, in PRCongo. Territorial. Co-operative breeder, with at least two adults in non-breeding plumage seen helping parents feed young at nest and after fledging. Oval nest with “beard” of dead leaves and short porch, built from dry leaves, fibres, fungi and filaments from spider webs (especially from the social spider *Agelena republicana*), lined with white pappus, and suspended up to 3 m above water from bush or tree; one nest was being built in *Martretia quadricornis* tree. Clutch 1–2 eggs, elongated, blue-grey with brown or purple-black lines, denser at wider end; no information on incubation and nesting periods.

Movements. Presumed resident. **Status and Conservation.** Not globally threatened. Rare or uncommon in most of range. More numerous in Gabon, where one pair every 500 m along rivers. Recently recorded from Korup National Park, in Cameroon.

Bibliography. Bannerman (1948), Borrow & Demeý (2001), Brosset & Éard (1986), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire & Dowsett (1991), Fry *et al.* (2000), Hall & Moreau (1970), Lynes (1938), Rand *et al.* (1959), Traylor (1962).

15. Little Green Sunbird

Anthreptes seimundi

French: Souimanga de Seimund **Spanish:** Suimanga de Seimund
German: Stutzschwanz-Nektarvogel
Other common names: Seimund’s Little Green Sunbird, Little Olive Sunbird

Taxonomy. *Cinnyris seimundi* Ogilvie-Grant, 1908, Banterbari, Bioko. Sometimes placed in genus *Nectarinia*; with such treatment, race name *minor* becomes invalid, as preoccupied, and must then be replaced by name *traylora*. Three subspecies recognized.

Subspecies and Distribution. *A. s. kruensis* (Bannerman, 1911) – W Guinea and Sierra Leone E to Togo. *A. s. minor* Bates, 1926 – SE Nigeria, Cameroon, S Central African Republic E to DR Congo, S Sudan, Uganda (Budongo Forest) and extreme NW Tanzania, S to NW & NE Angola. *A. s. seimundi* (Ogilvie-Grant, 1908) – Bioko I (Fernando Pôo).

Descriptive notes. 9.5 cm; male 6.3–11 g, female 5–6.5 g. A very small, green sunbird with short, minimally decurved, fairly thick bill and pale area around eye; lacks gloss and lacks pectoral tufts. Nominata race is olive-green above, with pale yellow crescents above and below eye, faint darker eyestripe; upperwing dark brown, feathers with yellow edges; tail dark brown, edged olive on outer webs; throat dull green-yellow, underparts paler than upperparts, yellower on belly, with all yellow along middle abdomen; undertail-coverts yellow, underwing white with yellow edging; iris dark brown; bill dark brown, paler base of lower

mandible; legs greenish-black. Differs from *Cinnyris batesi* in being paler and straighter-billed, with more yellow underparts, also in more prominent yellow around eye and mainly green (not brown) tail; from *Deleornis fraseri* in smaller size, yellow colour below, and lack of pectoral tufts. Sexes similar, but female smaller than male. Juvenile has dark crown and greyer flanks than adult. Race *kruensis* is duller below than nominate, tinged grey, with chin white, eyering less pronounced; *minor* is smaller than nominate, and greener (less yellow) below, has faint yellow supercilium, male with upper mandible greenish-black, lower mandible brownish-yellow with green-brown tip, female with base of lower mandible yellow. **VOICE.** Squeaky “twip twip twip” rapidly repeated up to eight times (race *kruensis*); “pse-ee” or “pss-upp”, repeated every second (*minor*).

Habitat. Most forest habitats, forest edge, forest–grassland mosaic, undergrowth in clearings and coffee plantations.

Food and Feeding. Takes nectar, small fruits of *Ochthocosmus africanus* and *Urera hypsilodendron*, seeds of figs (*Ficus*); also insects, such as small beetles (Coleoptera) and caterpillars, and small spiders (Araneae). Forages actively in forest trees, at all levels, in groups or in mixed-species flocks with other sunbirds. Visits *Astonia*, *Erythrina*, *Lophira alata*, *Macaranga assas*, *Mitragyna*, *Rauwolfia*, and mistletoes (Loranthaceae).

Breeding. Egg-laying in Feb in Sierra Leone, Jul in Liberia, Apr–May, Jul, Nov and Dec in Cameroon, Nov in Gabon, Oct in PRCongo, Feb and Sept in DR Congo, and Nov–Feb and Aug in Uganda; fledgling in Jul in Ghana. Compact oval nest of fibre and cobwebs or bark and dry leaves, lined with thistle down, hung near end of twig 10 m up in tree, covered above by foliage, or suspended from yam vine (*Dioscorea*). Clutch 2 eggs, unglossed, cream, with brown speckles all over; no information on incubation and nesting periods.

Movements. No data. **Status and Conservation.** Not globally threatened. Not uncommon in Cameroon, N Angola and Uganda, and abundant in Sudan (at Talanga forest); uncommon elsewhere, and rare in Guinea and DR Congo. Occurs in a number of protected areas.

Bibliography. Baker & Baker (2007), Bannerman (1948), Bates (1927), Borrow & Demeý (2001), Brosset & Éard (1986), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire (1990), Dowsett-Lemaire & Dowsett (2007), Fry *et al.* (2000), Hall & Moreau (1970), Lachenaud (2006b), Nikolaus (1987), Rand *et al.* (1959), Traylor & Archer (1982), Wolters (1965).

16. Straight-billed Green Sunbird

Anthreptes rectirostris

French: Souimanga à bec droit **German:** Goldband-Nektarvogel **Spanish:** Suimanga Piquirrecto
Other common names: Green Sunbird, Banded(!)/Banded Green/Green-backed/Western Green Sunbird; Yellow-chinned Sunbird (*rectirostris*); Grey-chinned Sunbird (*tephrolaemus*)

Taxonomy. *Certhia rectirostris* Shaw, 1811, no locality = Ashanti, Ghana. Forms a superspecies with *A. rubritorques*. Races sometimes treated as two distinct species. Proposed race *amadoni* (from Rumpi Hills, in W Cameroon) considered insufficiently distinct from *tephrolaemus*, differing from latter only in slightly smaller size; description of *pujoli* (from Guinea) is based on a juvenile specimen of nominate race. Two subspecies recognized.

Subspecies and Distribution. *A. r. rectirostris* (Shaw, 1811) – extreme S Mali, Sierra Leone and E & SE Guinea E to Ghana. *A. r. tephrolaemus* (Jardine & Fraser, 1851) – SE Benin and S Nigeria E, including Bioko I (Fernando Pôo), to S Central African Republic, DR Congo, S Uganda and W Kenya, S to NW Angola and NW Tanzania; also S Sudan (Imatong Mts).

Descriptive notes. 9–10 cm; 7–12 g. Very small sunbird with short, more or less straight bill, similar to that of Old World warbler (Sylviidae). Male nominate race is metallic green with golden tinge above, uppertail-coverts olive (sometimes metallic green); remiges and tail very dark brown with olive edges, upperwing-coverts brown, greater coverts with olive edges, lessers edged metallic green or blue; chin and throat lemon-yellow, bordered metallic green below, lower section of chest-band orange, plumage below this ashy grey, becoming pale yellow on belly and undertail-coverts; pectoral tufts lemon-yellow, under-

wing white, axillaries tipped yellow; iris dark brown or reddish-brown; bill and legs black. Distinguished from *Anthodidea collaris* by smaller size, straighter bill, yellow (not green) throat lacking gloss. Female is olive-green above, yellower on rump and uppertail-coverts, with hint of metallic green on head and back, pale olive-yellow supercilium and eyering, dark lores, dark brown wing and tail feathers edged olive, metallic edges on lesser wing-coverts, pale yellowish below, whiter on chin, brightest on belly. Juvenile is like female but without any iridescent feathering, crown and upperparts olive-brown, yellowish supercilium, underparts tinged yellow; older juvenile male has metallic feathers on crown and mantle and is brighter yellow below, developing yellow on throat before metallic or orange feathering. Race *tephrolaemus* male has chin and upper throat grey (smaller patch than yellow of nominate), larger area of metallic green on throat, and abdomen greyer than nominate, female darker, more brown, above than nominate, and juvenile greyer than that of nominate and tinged yellow. **VOICE.** Song (of race *tephrolaemus*) a series of rising and falling high-pitched phrases, e.g. “tser-tsit-tsee-too, tepu-ti-du-tepu-di-do, chup-chup-chup, churr”, finishing with “tser-tser-tser”. Calls high-pitched “psee-psee” repeated every 1–2 seconds, also a descending “tsi”, also “huit-huit-huit-huit”.

Habitat. Forests, gallery forests, swamp-forest, clearings, also cultivations of cocoa, coffee and oil palms (*Elaeis guineensis*); also inselbergs and mountains. From lowlands to 1100 m; to 1500 m in Uganda and at 700–2150 m in Kenya.

Food and Feeding. Takes termites (Isoptera), moth larvae (Lepidoptera), spiders (Araneae); also small berries, fruits of *Discoglyprena*, *Ochthocosmus africanus*, *Macaranga*, seeds of *Alchornea cordifolia*, and probably nectar. Attracted to flowers of *Turraeanthus* (Meliaceae), but perhaps in search of insects. Forages in pairs or family parties, or in mixed-species flocks, high in canopy, usually above 20 m. Searches for food on and below leaves, along branches and tree trunks, in warbler-like manner; sometimes hawks for insects.

Breeding. Egg-laying in Sept–Dec in Liberia, Dec in Ghana, Jun in Nigeria, Apr–Feb, Jun–Jul and Nov in Cameroon, Feb and Sept–Oct in PRCongo, Jan–Apr, Jul and Sept in DR Congo, and Aug in Uganda and Kenya; breeding in Nov in Tanzania. Territorial, sometimes in groups of 3–7 individuals. Probably co-operative breeder, at least occasionally, as young sometimes fed by adult helpers within group. Nest globular, that of nominate race made of stems and spider webs, adorned with flowers from kola tree (*Cola*), lined with white vegetable silk, suspended 2–40 m up; that of

tephrolaemus composed of fibres, lichens or moss, lined with cottony vegetable down or unidentified brown vegetable matter, with short mossy “beard”, suspended 1.5–10 m above ground. Clutch 2 eggs, grey, tinged violet, with dark grey-green spots and streaks; incubation by female alone, chicks fed by both parents, no information on duration of incubation and nestling periods; young sometimes fed by several adults.

Movements. Little information, but thought to move seasonally. Occurrence of this species mainly in non-breeding season in N Tanzania suggests some movement.

Status and Conservation. Not globally threatened. Common in Liberia, Equatorial Guinea, Gabon, S & W Uganda and W Kenya; not uncommon in Angola; uncommon elsewhere in range. Occurs in several protected areas.

Bibliography. Baker & Baker (2007), Bannerman (1948), Borrow & Demei (2001), Brosset & Éard (1986), Button (1967), Carroll (1988), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Christy & Clarke (1994), David & Gosselin (2002b), Dowsett-Lemaire (1996), Eiseentraut (1973), Éard (1979), Fry *et al.* (2000), Hall & Moreau (1970), Lachenaud (2006b), Lewis & Pomeroy (1989), Nikolaus (1987), Pérez del Val (1996), Prigogine (1978b), Quattrill & Quattrill (1998), Rand *et al.* (1959).

17. Banded Sunbird

Anthreptes rubritorques

French: Souimanga à col rouge **German:** Rotband-Nektarvogel **Spanish:** Suimanga Cuellirrojo
Other common names: Banded Green Sunbird, Usambara Grey-chinned Sunbird

Taxonomy. *Anthreptes rubritorques* Reichenow, 1905, Milalo, Usambara Mountains, Tanzania. Forms a superspecies with *A. rectirostris*. Monotypic.

Distribution. NE & E Tanzania: E Usambaras (Mt Nilo), W Usambaras, Ngurus, Nguus, Udzungwas (including Ndundulu Mts) and Ulugurus.

Descriptive notes. 8–9 cm; 10.5–11.9 g. Very small sunbird with short tail. Male is metallic green above; remiges brown, edged olive-green, scapulars, median and lesser wing-coverts metallic green, greater coverts duller, dull iridescent green; tail green with purplish sheen; grey below, narrow red breastband, yellowish central belly and undertail-coverts, orange-yellow pectoral tufts; underwing white; iris black or brown; bill and legs black. Distinguished from *Anthodiaeta pallidigaster* by green (not blue-green upperparts), grey underside with red breastband, yellow pectoral tufts. Female is duller above than male, with less

green metallic feathering on upperparts and ear-coverts, tail brownish, edged olive, throat whitish instead of grey, no breastband, otherwise olive below, yellowish centrally. Juvenile is blackish with olive tinge above, yellow-olive below. **VOICE.** Song by male Jun–Jan, from high in tree, “chip” or “teuu” repeated every second for up to a minute, sometimes on rising scale. Calls “thk-eeer” and far-carrying “shwerp”.

Habitat. Submontane forest and forest edge, including scrub near maize (*Zea mays*) plantations and junctions with miombo woodland and exotic plantations and gardens. Above 200 m; 1000–1350 m on Mt Nilo, 900–1600 m in Ulugurus.

Food and Feeding. Visits *Erythrina abyssinica*, *Grevillea*, *Macaranga kilimandscharica* and *Rubus* for nectar, small berries, fruits and insects. Forages in canopy of mature trees. Forages in pairs, in small parties or in mixed-species flocks; flocks of 60 individuals reported from both E & W Usambaras.

Breeding. Laying in Jan, Jul and Sept–Nov; active nest in late Dec. Nest built by female, attended by male, an oval structure without dangling “beard”, composed of *Usnea* lichens, cobwebs and vegetable matter, adorned externally with casuarina (*Casuarina*) needles, lined with pappus throughout (including ceiling), hung more than 15 m up in *Newtonia* or *Widdringtonia* tree. Male guards nest from nearby perch, calling often. Eggs evidently undescribed; incubation of eggs and feeding of young by female alone. No other information.

Movements. No data.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in Tanzania–Malawi Mountains EBA. Locally common in Usambaras; uncommon or rare in Udzungwas and elsewhere. Global population estimated at 10,000–19,999 individuals, and decreasing; total range estimated at c. 6700 km². Threatened by deforestation and forest degradation. In Usambaras and Ulugurus, large human population placing ever greater pressure on land, and increasing fragmentation of forest a problem; inaccessible nature of terrain effectively protects main block of montane forest in Ulugurus, although this covers no more than c. 120 km²; conservation projects here are directed at assisting local initiatives and increasing involvement of local communities in forest management. Forests in Nguru Mts, because of comparatively small local human population and precipitous terrain, believed not to be currently at risk. In Usambaras, occurs in area of East Usambara Catchment Forest Project and other reserves, such as Mount Nilo Forest Reserve; in Udzungwas, found in Udzungwa Mountains National Park and West Kilombero Scarp Forest Reserve.

Bibliography. Anon. (2007f), Baker & Baker (2007), Borghesio, John & Cordeiro (2007), Borghesio, John, Mulungu *et al.* (2008), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar & Stuart (1985), Cordeiro (1998), Evans (1997), Fry *et al.* (2000), Hall & Moreau (1970), Hipkiss *et al.* (1994), Moreau (1944), Moreau & Moreau (1937), Seddon *et al.* (1999a, 1999b), Stattersfield & Capper (2000), Stuart & Hutton (1977).

Genus *ANTHODIAETA* Cabanis, 1851

18. Collared Sunbird

Anthodiaeta collaris

French: Souimanga à collier **German:** Waldnektarvogel **Spanish:** Suimanga Acolorado

Taxonomy. *Cinnyris collaris* Vieillot, 1819, Gamtoos River, Cape Province, South Africa. Genus formerly subsumed in *Anthreptes*; recently, this species and its three congeners were placed in a genus *Hedydipna*, but this name invalid, current genus name having precedence. Has been suggested that races *subcollaris*, *hypodila* and *zambesiana* represent one or more separate species,

on basis of reduced (or lack of) iridescence in plumage of juveniles (whereas metallic colours present even on nestlings of *somereni*); further study required. Other proposed races are *nigeriae* (described from Overri, in SE Nigeria), considered inseparable from *subcollaris*; *ugandae* (from Maraquet, Kenya) and *phillipsi* (R Lofu, in Zambia), both synonymized with *garguensis*; *jubaensis* (Hellesheid, on R Jubba, in S Somalia), merged with *elachior*; *chobiensis* (R Chobe, in N Botswana), subsumed in *zambesiana*; and *patersoniae* (lower R Pungwe, in E Zimbabwe) and *beverleyae* (R Limpopo, in S Zimbabwe), both considered indistinguishable from *zuluensis*. Nine subspecies recognized.

Subspecies and Distribution.

A. c. subcollaris (Hartlaub, 1857) – Senegal and Guinea-Bissau E to coastal Nigeria (E to Niger delta).

A. c. hypodila (Jardine & Fraser, 1851) – Bioko I (Fernando Póo).

A. c. somereri (Chapin, 1949) – SE Nigeria E to S Central African Republic and SW Sudan (W of R Nile), S to NW Angola (Cabinda, S to Cuanza Norte and Cuanza Sul) and N DR Congo.

A. c. djamdjensis (Benson, 1942) – SW Ethiopia (R Algehe and R Sagan area).

A. c. garguensis (Mearns, 1915) – S Sudan (E of R Nile), E & SE DR Congo, Uganda, W Kenya, Rwanda, Burundi, W Tanzania, W Zambia (S to Ngoma) and CE Angola (Alto Zambesi to Vila Luso and Malanga).

A. c. elachior (Mearns, 1910) – coastal E Africa from S Somalia (S from Jubba S of 4° N) S to Kenya (inland to Kenya Highlands) and NE Tanzania (inland to Moshi and Kilosa, S to Dar es Salaam), also Pemba I, Zanzibar and Mafia I.

A. c. zambesiana Shelley, 1876 – NE Angola (Malanje E to Mexico), S DR Congo and SW Tanzania S to S & E Zambia, Malawi, N Botswana, N Zimbabwe (Zambezi valley, Ngamiland and S Barotseland) and C Mozambique.

A. c. zuluensis Roberts, 1931 – E highlands of Zimbabwe and S Mozambique (S from Gorongosa) S to E Swaziland and NE South Africa (Mpumalanga, NE KwaZulu-Natal).

A. c. collaris (Vieillot, 1819) – SE South Africa from S KwaZulu-Natal S to Eastern Cape and SE Western Cape (Knysna).

Descriptive notes. 10–10.5 cm; male 5.3–11 g, female 5.4–9.7 g. Small sunbird with short, slightly curved bill. Male nominate race is bright metallic golden-green above, also on chin and throat, with upptail-coverts more pure green; upwing dark brown, lesser and median wing-coverts bright metallic green, greater coverts, secondaries and tertials broadly edged green, primaries with narrow olive-green edging; tail blackish, glossed dark green, feathers edged bright metallic green; green of throat bordered below by narrow purple breastband, underparts yellow, pectoral tufts bright yellow, flanks tinged olive; iris dark brown or blackish; bill and legs black. Female is like male but lacks green and purple below, has chin and throat dusky olive, becoming yellower below. Juvenile resembles female. Race *subcollaris* male is brighter green above than others, with less green in wing, brighter orange-yellow below, purple breastband broader than in nominate, female has buff throat with metallic green mottling at side, juvenile distinctive, has olive-tipped grey head feathers, olive forehead with faint metallic green sheen, greyer crown and nape, yellow streak above and below eye, cheek and throat side yellow-olive, back, wing and upptail-coverts bright olive, metallic green patch on shoulder, tail brown with olive edging, throat to upper breast pale grey-white, merging with pale yellow on belly; *hypodila* has brilliant metallic feathering and is duller yellow below than previous; *somereri* has palest and dullest yellow underparts of all races, flanks dark olive, female throat dusky yellow; *zambesiana* male has secondaries edged yellow, wing-coverts with little or no green on margins, underparts deep yellow, almost no olive on flanks; *djamdjensis* male is similar to previous but brighter yellow below, female with this richer yellow colour extending to lower throat; *elachior* is much paler below than last, especially in female; *garguensis* male is deep yellow below, with flanks tinged greener than in *zambesiana*, female has throat to chest olive-grey, flanks dark green; *zuluensis* differs from nominate in having secondaries edged yellow, male wing-coverts with narrower green edges. **VOICE.** Song of race *subcollaris* high-pitched “tsi-tsu-tsu-tsu-tsi-tsu-tsu-tsu-tsi” with single notes interspersed; of *elachior* a “dzer” introductory note before brief series of “tsee-ou” notes, as e.g. “busy-busy-busy...busy”; nominate song deeper “chip-chip-chip...chip”; female, too, sings, sometimes from nest. Varied calls include loud “tsweet-tsweet” or “tserp-tserp”, or “cherreee” or “tsewrew”, and high-pitched “chi-chi” during courtship; repetitions of “tsk-tsk” in flight.

Habitat. Forest, woodland and savanna; particularly common in open areas such as forest edges, clearings, cultivations and gardens. Sea-level to 2600 m.

Food and Feeding. Diet mostly insects, also spiders (Araneae), snails; also seeds and small fruits, e.g. of *Chrysanthemoides*, *Macaranga*, *Ochthocosmus africanus*, *Rauwolfia vomitoria*, *Tetrorchidium didymostemon*, *Trema orientalis*, and berries of *Alchornea cordifolia*. Attracted to sweet liquid exuding from exit holes of fig-wasp *Elisabethiella baijnathi* in fruits of the fig *Ficus burtt-daveyi*, and possibly also nectarivorous. Visits wide range of foodplants, including *Acacia abyssinica*, *Achyrosporum carvalhi*, *Acrocarpus fraxinifolius*, *Berlinia grandiflora*, *Burchellia bubalina*, *Caesalpinia pulcherrima*, *Clematis simensis*, *Clerodendrum johnstonii*, *Combretum paniculatum*, *Dombeya goetzenii*, *Englerina woodfordioides*, *Faurea saligna*, *Grevillea banksii*, *Grewia similis*, *Halleria lucida*, *Helinus mystacinus*, *Leonotis mollissima*, *Leonotis nepetifolia*, *Leucas densiflora*, *Macrorrhiza pubinervis*, *Mimusops caffra*, *Petrea nobilis*, *Ruspolia hypocrateriformis*, *Schotia speciosa*, *Sericostachys*, *Sireltzia nicolai*, *Symphonia globulifera*, *Syzgium guineense*, *Tecoma capensis*, *Tetrorchidium didymostemon*, *Triumfetta macrophylla*, *Xylopia aethiopica* (arils), various unidentified mistletoes (Loranthaceae), and plants of genera *Albizia*, *Aloe*, *Anthocleista*, *Catunaregam*, *Erythrina*, *Eucalyptus*, *Fuchsia*, *Gouania*, *Hibiscus*, *Kalanchoe*, *Lantana*, *Pavetta*, *Rytigynia*, *Salvia*, *Stereospermum*. Drinks from birdbaths. Forages in pairs and family parties; joins mixed-species flocks. Forages actively in manner of Old World warbler (Sylviidae) or tit (Paridae), leaf-gleaning in low bushes and overgrown areas at edge of clearings or plantations, but also in creepers on forest trees at up to 25 m; sometimes hangs upside-down to feed. Hawks for insects; hovers at flowers.

Breeding. Laying Dec in Senegal, breeds all months (peak Oct–Apr) in Liberia, most months in Ghana, Jan, Apr, Jul, Sept–Oct and Dec in Nigeria, Jan–Jun and Oct–Dec in Cameroon, Nov–Apr and Jul in Gabon, Sept–Nov in PR Congo, Jan and Aug–Sept in DR Congo, laying May and Oct in Angola; Jan, Apr and Oct–Nov in extreme S Sudan, Dec in Somalia, Jan–Dec in E Africa (peak Sept–Oct in Tanzania, Apr–Nov on Zanzibar), Jan–May, Jul–Oct and Dec in Malawi, and Jan, Mar–Apr, Aug–Sept and Dec in Zambia; Jun and Oct in Botswana, Sept–Jan and Apr–May in Zimbabwe, Jan, Mar–May and Aug–Dec in Mozambique, and in all months (mainly Sept–Feb) in South Africa. Territorial males chase each other, while clicking wings; polyandrous and polygynous groups also recorded. Female builds nest, taking 1.5–7 days, structure pear-shaped, 82–165 mm

tall, 52–76 mm wide, 64–88 mm deep, sometimes with dangling “beard” of dead leaves and cobwebs (up to 75 mm long), lateral entrance hole 25–45 mm across sited c. 4 cm from top, some having porch above entrance extending c. 3 cm out, composed of grass, fibres, dead leaves, leaf mould, spider webs and twigs, occasionally adorned with lichen, bark, seeds or flowers, lined with feathers, kapok or other vegetable matter, suspended 1.5–8 m above ground from branch. Clutch 1–4 eggs, white to light brown, bluish, green or pinkish, with bold brown, olive or grey markings denser at broad end; incubation by female, male occasionally assisting, period 12–14 days (up to 19 recorded, perhaps because female did not start immediately after egg-laying); chicks brooded by female, which sometimes fed at nest by male, provisioning of chicks by both sexes, nestling period 14–17 days; fledglings dependent on parents for up to 24 days after leaving nest. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*). Nestlings sometimes taken by monkeys.

Movements. Mainly sedentary; one ringed individual moved 7 km.
Status and Conservation. Not globally threatened. Common and widespread throughout almost entire range. Occurs in many protected areas, examples being Abuko Nature Reserve, in Gambia, Korup National Park, in Cameroon, Mikumi National Park, in Tanzania, and Lilongwe Nature Sanctuary, in Malawi.

19. Pygmy Sunbird

Anthodiaeta platyura

French: Souimanga pygmée **German:** Grünbrust-Nektarvogel **Spanish:** Suimanga Pigmeo
Other common names: Pygmy Long-tailed/Western Pygmy/Southern Pygmy Sunbird

Taxonomy. *Cimyrus platyrus* Vieillot, 1819, Senegal. Genus formerly subsumed in *Anthreptes*; recently, this species and its three congeners were placed in a genus *Hedydipna*, but this name invalid, current genus name having precedence. Forms a superspecies with *A. metallica*, and formerly treated as conspecific. Monotypic.
Distribution. W & S Mauritania and Senegal E to Sudan and W Ethiopia, S to N Guinea, N Ivory Coast, N Cameroon, NE DR Congo, Uganda and NW Kenya.

Descriptive notes. Male 9–16 cm (including tail), female 8–9 cm; 5.7–7 g. Small sunbird with short decurved bill. Male in breeding plumage has crown and upperparts metallic green with bronzy or coppery red sheen, metallic purplish-blue rump and uppertail-coverts; lesser upwring-coverts and outer margins of inner median and greater coverts metallic green, remiges dark brown; tail black, tinge of steel-blue gloss, central pair of rectrices protruding 55–80 mm beyond the rest and with racquet-shaped widening at tips; chin to upper breast metallic green, tinged bronzy, otherwise bright yellow below, flanks and

undertail-coverts paler, occasionally a thin violet strip below green of lower throat; axillaries black or greyish-black, mixed with yellow, especially on shafts; iris black or dark brown; bill and legs black. Distinguished from *A. metallica* mainly by lacking or having very narrow violet band on upper breast, rather than a broad blue-purple band. Non-breeding male (eclipse plumage) loses elongated central rectrices, resembles female, but metallic green on wing-coverts and black underwing feathers retained, and some green may remain on body, uppertail-coverts and throat, on latter forming bib. Female lacks tail streamers and metallic plumage, is greyish-brown above, washed olive on rump, with wings, wing-coverts and back brown (back paler), rump pale greenish-yellow, tail very dark brown, tinged dark blue; broad buff stripe over eye; pale yellow below, throat paler, flanks greenish, axillaries and inner underwing-coverts pale yellow, others white, iris brownish-black, faint pale eyering. Juvenile male is initially as female, but soon acquires bright yellow on underparts and some metallic green in plumage; immature female has grey throat, otherwise grey-brown below, eyestrype yellowish. Voice: Song 3–4 seconds long, consisting of such phrases as “pseu-pseu-pseu-der-dzer-dzer” or “ti-ti-ti-ti-ti-ti” or “pserr-pserr-pserr” or “pser-eee” and some trilling, repeated every 10 seconds. Male contact call “cheek-cheek”, and similar “cheek” call by nest-building female; other calls include “twee-weet”, “tsuup-tsuup-tsuup” and “tsei”.

Habitat. Dry acacia (*Acacia*) woodland, thorn-scrub, savanna woodland and Sahelian vegetation; also visits gardens.

Food and Feeding. Nectar, pollen, acacia petals; also insects, including ants (Formicidae), and spiders (Araneae). Visits many flowering plants such as aloes (*Aloe*), acacia, neem trees (*Azadirachta*), cotton trees (Bombacaceae), flame trees (e.g. *Delonix regia*) and mistletoes (Loranthaceae). Forages singly, in pairs and in family parties; sometimes associates with mixed-species groups. Hovers at flowers; also hangs upside-down to feed.

Breeding. Nests in dry season, laying Jan–Mar and Aug–Sept in Mauritania, Feb–Mar and Sept in Senegambia, Feb–Mar in Burkina Faso and Togo, Dec in Niger, Dec–Apr in Nigeria, Feb in Cameroon and DR Congo, Feb–May in Sudan, and Oct and Dec in E Africa; occasionally double-brooded. Territorial male displays by bowing to female, cocking tail and drooping wings. Nest, built by female, an oval structure 85–100 mm tall, 45–53 mm wide and up to 62 mm deep, with entrance 30 mm wide and short porch (25 mm), made of grass, leaves and feathers held together with spider webs, lined with vegetable matter, decorated externally with dead leaves, seeds and cocoons (but no dangling “beard”), placed 1.5–4 m above ground in body of thorn bush (e.g. *Acacia*, *Bougainvillea*, *Balanites*, *Dichrostachys*). Clutch 1–2 eggs, glossy white or sky-blue; incubation by female alone, period 14 days; chicks fed by both parents, nestling period 12–15 days; both parents also attend to fledglings.

Movements. Resident or partial migrant in far N of range (e.g. Air, in Niger). In W Africa moves S from the Sahel to breed in savanna areas (Oct–Apr), returning N with beginning of rains (Mar–May); thus only a dry-season visitor in most of S range. Those breeding in DR Congo late Dec to Mar possibly come from Sudan.

Status and Conservation. Not globally threatened. Common and widespread throughout most of range. Occurs in several protected areas, e.g. Comoé National Park, in Ivory Coast, and Waza National Park, in Cameroon.

Bibliography. Bannerman (1948), Bates (1927, 1934), Borrow & Demeý (2001), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Cramp & Perrins (1993), Fry *et al.* (2000), Hall & Moreau (1970), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1945), Nikolaus (1987), Petiet (1977), Serle (1940, 1957), Skinner (1969), Thonnerieux *et al.* (1989), Walsh *et al.* (1990).

20. Nile Valley Sunbird

Anthodiaeta metallica

French: Souimanga du Nil **German:** Erznektarvogel **Spanish:** Suimanga del Nilo
Other common names: Eastern Pygmy/Northern Pygmy Sunbird, Bronzed Pygmy Sunbird, Metallic Sunbird

Taxonomy. *Nectarinia metallica* M. H. C. Lichtenstein, 1823, Dongola, Sudan. Genus formerly subsumed in *Anthreptes*; recently, this species and its three congeners were placed in a genus *Hedydipna*, but this name invalid, current genus name having priority. Forms a superspecies with *A. platyura*, and formerly treated as conspecific. Birds from NW Ethiopia (Melissai, on Adiabo Plains) with apparently short wing described as race *adiabonensis*, but considered inadequately differentiated from those elsewhere in species’ range. Monotypic.

Distribution. Egypt (R Nile and CE coast), Sudan, Eritrea, W, N & E Ethiopia, Djibouti and S Arabia (Saudi Arabia S of Jeddah, Yemen, SW Oman). Non-breeding visitor to E Ethiopia and N Somalia.

Descriptive notes. Male 17 cm, female 9 cm; 7–7.5 g. Small sunbird with short decurved bill. Male in breeding plumage has head to upper chest and upperparts to back dark metallic green with dark purplish-blue gloss, rump and uppertail-coverts shiny dark bluish-purple; upwring-coverts as back, primary and greater coverts and bastard wing black, greater coverts with metallic blue-green edges; flight-feathers black, tinged brown, tertials black with blue gloss; tail black, tinged dark metallic blue and edged greenish, central pair of feathers extending 50–70 mm beyond rest and with racquet-shaped tips; dark purplish-blue strip

below green on chest, rest of underparts yellow, flanks and undertail-coverts paler; underwing dull black; iris dark brown; bill and legs black. Non-breeding male (eclipse plumage) is similar to female, but flight-feathers and tail brownish-black with blue-green tinge (not brown); in second and subsequent non-breeding dress has black in centre of throat. Female lacks metallic plumage colours and elongated tail feathers, has top and side of head and upperparts grey-brown, faint yellowish-green gloss on forehead and neck, pale cream to whitish-yellow supercilium and light brown eyestrype, dark grey-brown remiges, pale yellow below, brightest in central region. Juvenile is similar to female, but upperparts pale greenish-grey, supercilium duller yellow, remiges brownish-grey. Voice: High-pitched warbling song, as “pruiit-pruiit-ptuiit-tiriririri-tiririri”, and miscellaneous chatters. Contact call “pee”; other calls similar but of 2 notes, second higher-pitched.

Habitat. Arid scrub and gardens near irrigation, from sea-level to 2200 m.

Food and Feeding. Nectar, also insects. Nectar taken from many flowers, e.g. oleander (*Nerium oleander*), mistletoes (Loranthaceae), *Calotropis procera*, *Maurea crassifolia*, *Rhazya stricta*, and species of genera *Acacia*, *Bombax*, *Capparis*, *Hibiscus*, *Jacaranda*, *Parkinsonia*. Usually in pairs, but in non-breeding season congregates in groups of up to 70 individuals; sometimes in mixed-species groups. Takes insects by leaf-gleaning, also by hawking.

Breeding. Laying Apr–May in Egypt, Jan–Nov in Sudan, Dec–May in Saudi Arabia, Mar–Apr in Yemen and May in Oman. Territorial; singing male flicks wings, spreads tail and quivers body. Male has dancing hovering display-flight with whirring wings, also courts female by rocking body to and fro and moving head from side to side; female joins dance before mating. Nest, built by both sexes, an elongated ovoid structure 9–12 cm tall, 5 cm wide, entrance hole 25 mm across, composed variously of grass stems, plant fibres, rootlets, dead leaves, wool, flowers, feathers, seeds, hair, spider egg cases and nylon string, bound with spider web, lined with white down and feathers, attached by rear surface to branch 1.5–10 m up in body of thorn tree or on external branch, or suspended from shrub. Clutch 1–4 eggs, glossy pinkish-white, finely speckled at larger end with rufous on larger grey areas; incubation by female alone; no information on duration of incubation and nestling periods.

Movements. Movement into Cairo area of Egypt in Oct–Mar. Movements in Red Sea hills of Sudan in summer, and flowering acacias attract migrants to coast of Eritrea, Jan–Jun. Influxes recorded in Somalia and Ethiopia in Sept–May, Saudi Arabia in Oct and Oman in Nov–Feb.

Status and Conservation. Not globally threatened. Common; sometimes abundant locally. Occurs in a number of protected areas, such as the Awash National Park, in Ethiopia.

Bibliography. Ash & Miskell (1983), Baha el Din (1992), Cheke & Mann (2001), Cramp & Perrins (1993), Eriksen (1998), Evans (1992), Evans & Dijkstra (1993), Fry *et al.* (2000), Hall & Moreau (1970), Jennings (1995), Mackworth-Præd & Grant (1945), Meininger & Mullic (1981), Nikolaus (1987), Rahmani *et al.* (1994), Zedlitz (1910).

21. Amani Sunbird

Anthodiaeta pallidigaster

French: Souimanga d’Amani **German:** Amaninektarvogel **Spanish:** Suimanga de Amani
Other common names: Pale-bellied Sunbird

Taxonomy. *Anthreptes pallidigaster* W. L. Sclater and Moreau, 1935, 4 miles [6.4 km] east of Amani, north-east Tanzania.

Genus formerly subsumed in *Anthreptes*; recently, this species and its three congeners were placed in a genus *Hedydipna*, but this name invalid, current genus name having precedence. Males in Ndundulu Mts, in C Tanzania, are brighter metallic blue, less green, than those elsewhere in species’ range, and possibly represent an undescribed geographical race; further study required. Monotypic.

Distribution. Coastal SE Kenya (Sokoke-Arabuko Forest) and NE & C Tanzania (E Usambara Mts and nearby, and Ndundulu Mts).

Descriptive notes. 8–9 cm; 6–8 g. A very small sunbird with short, decurved bill. Male has head to upper back, scapulars and upwring-coverts (except greater) dark iridescent purplish blue-green, blackish lower back and rump, metallic purplish-blue uppertail-coverts and tail; remiges and greater wing-coverts blackish-brown; chin and middle of throat to upper chest metallic dark purple-blue, surrounded by metallic dark green; otherwise grey-white below, pectoral tufts orangey red with

yellow at base; white underwing; iris dark brown; bill and legs black. Female is dark grey above and on side of head, with white supercilium, minimal metallic feathering scattered on head and hindneck, but silver-green metallic feathers on lesser and median upperwing-coverts and uppertail-coverts, dark brown wing, blue-back tail with white tips (both surfaces), white below, including underwing-coverts. Juvenile is as female, but washed pale yellow from lower breast to vent, has white patch from base of bill to above centre of eye, dark blue tail lacks white tips; purple tinge visible on throat of juvenile male. Voice. Com-

plex song consists of a random sequence of high-pitched, ascending and descending "chissick" chirps. Calls include characteristic and loud "seer-seer", followed by twittering; "chip", soft "zee-eeee", and "seeet-seeet".

Habitat. *Brachystegia* (*Brachystegia*) woodland in coastal Kenya, and forest and forest clearings in Tanzania; also gardens and degraded forest. From lowlands to 1550 m.

Food and Feeding. Caterpillars, spiders (Araneae), presumably also nectar. Forages at 5–35 m, alone or in groups of up to 60; joins mixed-species flocks. Feeds at *Allanblackia stuhlmannii*, *Erythrina*, *Grevillea* and mistletoes (Loranthaceae). Sometimes hangs upside-down; also hawks for insects.

Breeding. Laying in Mar, May–Jun and Sept–Dec. Nest-building, by female, takes one week; nest of fine plant fibres, lichen and down, with "beard" of lichen, lined with pappus, outer covering and porch over side entrance of *Usnea* lichens, providing good camouflage, suspended 7–14 m above ground, sometimes in *Brachystegia spiciformis* tree, also in eucalypt (*Eucalyptus*) plantation. Clutch 3 eggs, beige, with heavy brown markings concentrated at wider end; incubation by female only; no information on duration of incubation and nestling periods; both sexes feed fledglings.

Movements. Local short-distance movements in search of flowering plants.

Status and Conservation. **ENDANGERED.** Restricted-range species: present in Tanzania–Malawi Mountains EBA and East African Coastal Forests EBA. Global population estimated to lie in range 10,000–19,999 individuals, and decreasing; estimated total geographical range c. 870 km². Range very small and fragmented: occurs in Arabuko-Sokoke Forest, in Kenya, and in four areas in E Usambara Mts and two areas in Udzungwas, in Tanzania. Most populations threatened by deforestation; competition with *A. collaris* possibly has an additional adverse effect. In Sokoke, 2900–4700 pairs (1 pair/1.5–2.4 ha) estimated in 1970s, and densities of 1.4 birds/km transect in 1999. In Udzungwas, occurs in c. 295 km² of suitable habitat at 1350–1550 m; these populations in isolated areas, away from humans, and therefore better protected. Long-term forest conservation through sustainable management and community participation is underway in Arabuko-Sokoke; in Tanzania, three active conservation projects in E Usambaras, together covering at least 121 km².

Bibliography. Anon. (2007f), Baker & Baker (2007), Borghesio, John & Cordeiro (2007), Borghesio, John, Mulungu *et al.* (2008), Britton & Britton (1978), Britton & Zimmerman (1979), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar & Stuart (1985), Cordeiro (1998), Davis (2005), Dinesen *et al.* (1993), Fjeldså (1999), Fry *et al.* (2000), Hipkiss *et al.* (1994), Irwin (1996), Oyugi & Kombe (2004), Seddon *et al.* (1999a, 1999b), Stattersfield & Capper (2000), Stuart & Hutton (1977).

Genus *HYPOGRAMMA* Reichenbach, 1853

22. Purple-naped Sunbird

Hypogramma hypogrammicum

French: Souimanga strié **German:** Streifenektarvogel **Spanish:** Suimanga Estriado
Other common names: Blue-naped/Banded Sunbird(!)

Taxonomy. *Nectarinia hypogrammica* S. Müller, 1843, Sumatra and Borneo. No obvious close relatives; tongue morphology unique within family, on which grounds this species may even merit placement in its own subfamily. Five subspecies recognized.

Subspecies and Distribution.

H. h. lisettiae (Delacour, 1926) – N Myanmar, S China (SW Yunnan), N Thailand and N & C Indochina.

H. h. nuchale (Blyth, 1843) – S Myanmar, S Thailand and Peninsular Malaysia.

H. h. mariae (Deignan, 1943) – S Indochina, including E Cambodia.

H. h. natunense (Chasen, 1935) – N Natuna Is.

H. h. hypogrammicum (S. Müller, 1843) – Sumatra and Borneo.

Descriptive notes. 12.7–15 cm; male 7.8–15.2 g, female 9.7–13.5 g. Distinctive large sunbird with streaked underside. Male nominate race is dark olive-green above, with metallic purple-blue nuchal band and lower back to uppertail-coverts, often some white bases showing through on rump; tail all dark olive, outer rectrices with white tips (all except central rectrices narrowly tipped white below); throat greyish-white, becoming olive-yellow downwards, vent dark olive-green, yellow to olive-yellow undertail-coverts; throat, breast and upper belly boldly streaked dark olive; iris red or brown; bill black to brownish-black; legs

brown, brownish-green or olive. Female is smaller than male and lacks metallic coloration. Juvenile apparently undescribed. Racial differences rather subtle: *lisettiae* is longer-billed than nominate, male gloss is distinctly purple, collar on average narrower than nominate, breast and abdomen paler yellow, undertail-coverts brighter yellow, no white in metallic colour of rump, and underside of all except central rectrices tipped yellowish-white; *mariae* male differs from previous in having upper surface of central rectrices black with narrow olive-green edges, remaining rectrices broadly tipped white, underparts less yellow than in other races; *nuchale* male has gloss more purple and less blue than nominate, underside of all rectrices except central pair broadly tipped white; *natunense* differs from last in having larger bill and more finely marked throat. **Voice.** Song a high-pitched, strong “sweet-sweet-sweet, sweet, sweet”. Calls strident “schwerp”, sharp “chwep” and “tsit-tsit”. **Habitat.** Variety of forest types, including peatswamp-forest, secondary growth, plantations, open swamps; occasionally in gardens. Sea-level to at least 1200 m.

Food and Feeding. Insects, spiders (Araneae), also nectar, fruits and seeds. Generally forages low down, below 5 m, but sometimes higher. Raids spider webs for trapped prey.

Breeding. Laying at least Mar and May–Jul in Malay Peninsula, where juveniles recorded Jan–Oct; in Borneo, laying Aug in NW (Sarawak), and birds with active gonads in Jan–Mar, May–Aug, Nov and Dec and nest-building Jan in N (Sabah). Nest pear-shaped or an untidy pendent ball, made of grass, rootlets, bark, lichen, dry moss, leaves and cobwebs, loosely decorated with various materials which may hang up to 15 cm below nest, lined with cotton down, and fixed to underside of plantain (*Musa*) leaf or palm frond 6 m above ground. Clutch 2–3 eggs, whitish with overall uneven suffusion of lilac-grey, with dark grey and black scribbles and irregular blotchings, especially at broad end; no information on incubation and nestling periods; fledglings attended by both parents.

Movements. None recorded.

Status and Conservation. Not globally threatened. Uncommon in Thailand; common in parts of S Laos; common in Peninsular Malaysia; locally common in Sumatra and Borneo. Occurs in several protected areas, including e.g. Cat Tien National Park, in Vietnam, Taman Negara National Park, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, and Danum Valley Conservation Area, in Borneo.

Bibliography. Genus *ANABATHMIS* Reichenow, 1905

23. Reichenbach’s Sunbird

Anabathmis reichenbachii

French: Souimanga de Reichenbach **Spanish:** Suimanga de Reichenbach
German: Reichenbachnektarvogel

Taxonomy. *Nectarinia reichenbachii* Hartlaub, 1857, Gabon.

Genus previously merged with *Nectarinia*. Monotypic.

Distribution. S Liberia E to S Nigeria, Cameroon, Central African Republic and DR Congo (E to middle and upper R Congo and Kivu), S to N Angola.

Descriptive notes. 12–14 cm; 7–13 g. Distinctive sunbird with graduated tail. Male has head to chin and throat metallic dark steel-blue with iridescent green and violet sheen; back of head and upperparts olive-green, brown feather centres on mantle and scapulars (creating mottled effect),

rump and uppertail-coverts olive mixed with olive-yellow; upperwing dark brown, edged olive; rectrices blackish-brown, all except central pair with wide pale brownish-white tips; pale grey below, lower belly and vent yellow, pectoral tufts yellow or orange-yellow, underwing white; iris dark brown; bill and legs black. Female is like male but slightly smaller, with duller yellow pectoral tufts. Immature is similar to adult, but has dark olive head, black mottling on crown, yellow supercilium, olive-yellow cheeks and underparts, dark brown barring on throat. **Voice.** Song, from high perch such as top of coconut palm (*Cocos nucifera*),

consists of high-pitched trills and whistles e.g. “tser-pit-too-tu-wee” and “witssooo” and “weee”, and “tser-pert-ta-tee”, sometimes ending in “tsee-too”, the whole lasting for a minute or more. Calls include disyllabic “chirr-up”, and variations on “psi-ou” or “tchu-ih-tchu-ih”.

Habitat. Coastal swamps, scrub, palm groves in sandy zones, mangroves, rice fields, forest clearings, beside watercourses, and in gardens; nearly always near water.

Food and Feeding. Insects and nectar. Forages singly or in pairs, 5–30 m up in trees within 500 m of water. Hawks for insects. Takes nectar from coconut palm, *Psychotria djumensis*, *Sabicea africana*, *Stipularia africana*, and mistletoes such as *Englerina gabonensis* and *Globimetula braunii*. **Breeding.** Egg-laying in May, Jun and Sept–Dec in Cameroon, Sept–Oct and Dec in PR Congo, and Feb and Oct–Nov in Gabon; immature in Liberia in Sept. Nest, built in 5 days, a small pouch-shaped structure, made of grass, dead leaves, fibres and spider webs, unlined, hung 1–5 m above water among papyrus, *Mimosa nigra* and scattered trees. Clutch 1–2 eggs, matt light chocolate-brown or grey-buff with dark speckles, latter denser at wide end; incubation by female alone; no information on duration of incubation and nestling periods.

Movements. No data.

Status and Conservation. Not globally threatened. Common from Cameroon S to PR Congo; elsewhere locally not uncommon (Nigeria, Ivory Coast), but often scarce or rare. Occurs in a few protected areas.

Bibliography. Bannerman (1948), Bartlett & Anderson (1987), Borrow & Demey (2001), Brosset & Énard (1986), Cane & Carter (1988), Chapin (1954), Cheke & Mann (2001), Demey (1986), Dowsett *et al.* (1993), Dowsett-Lemaire & Dowsett (1991), Eccles (1985), Eisentraut (1963), Fry *et al.* (2000), King *et al.* (2004), Kirkup (1998), Lachenaud (2006a), Rand *et al.* (1959).

24. Principe Sunbird

Anabathmis hartlaubii

French: Souimanga de Hartlaub **German:** Hartlaubnektarvogel **Spanish:** Suimanga de Principe
Other common names: Hartlaub’s Sunbird

Taxonomy. *Nectarinia hartlaubii* Hartlaub, 1857, “Angola”; error = Principe, Gulf of Guinea.

Genus previously merged with *Nectarinia*. Monotypic.

Distribution. Principe I, in Gulf of Guinea.

Descriptive notes. 13–14 cm; 10.4 g. Fairly large, dark sunbird with graduated tail. Male is olive above, uppertail-coverts black, edged metallic green; upperwing brown, edged olive; tail feathers dark blue with metallic tinge, all except central pair with buffish-white tips; chin to upper breast metallic dark blue and reflecting violet; lower breast greenish-olive, merging into yellowish on rest of underparts; underwing-coverts and axillaries white; iris chestnut-brown; bill and legs black. Female is as male, but throat olive with dark barring, lacking metallic plumage. Juvenile is like female, but has dark grey-brown throat (blackish-grey on young male) and chest. **Voice.** Noisiest in late afternoon. Song is repetitions of “peek-oo-wee, peek-oo-wee” or “pstes-to-ichou, pstes-to-ichou”, with occasional “twee” whistles, or “tik-e-tik, tik-e-tik, tik-e-tik, ee-tik” or a fast “tiu-tiu-huit-tiu-tiu-huit”. Call very persistent, of 2–3 notes, “dreee” or “too-wee”, or “wee wee”, and variations on “psit-sit”; female utters quiet high-pitched notes.

Habitat. Forest (except montane forest), cultivations, plantations, scrub, gardens; ubiquitous.

Food and Feeding. Insects, including ants (Formicidae) and aphids (Aphidoidea); also nectar. Forages singly, in pairs or in groups of up to ten individuals. Forages at all levels; seeks insects mostly at low levels in trees, or on ground. Takes nectar from flowers of coconut (*Cocos nucifera*), banana (*Musa*) and *Erythrina* trees.

Breeding. Season Oct–Feb/Mar; laying recorded in Feb, and juveniles seen in all months. Nest 17–20 cm tall, with short porch and short “beard”, made of palm bark and dead leaves, lined with plant down and feathers, suspended 1–7 m up from small branch or twigs. Clutch 2 eggs, white, densely covered with reddish spots. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Principe EBA. Common to c. 150 m, except in dense woodland.

Bibliography. Amadon (1953), Bannerman (1948, 1951), Borrow & Demey (2001), Cheke & Mann (2001), Christy & Clarke (1998), Fry *et al.* (2000), Jones & Tye (2006), de Naurois (1994), Sinclair & Ryan (2003).

25. Newton’s Sunbird

Anabathmis newtonii

French: Souimanga de Newton **Spanish:** Suimanga de Newton
German: Gelbburst-Nektarvogel
Other common names: (Newton’s) Yellow-breasted Sunbird, Sao Tome Sunbird(!)

Taxonomy. *Cinnyris newtonii* Bocage, 1887, São Tomé, Gulf of Guinea.
Genus previously merged with *Nectarinia*. Monotypic.
Distribution. São Tomé, in Gulf of Guinea.

Descriptive notes. 10–11 cm; 6–9 g. Male is dark olive above, forecrown paler, uppertail-coverts black, tinged metallic green at tips; upperwing dark brown, edged dark olive; tail black, central feather pair glossy, remainder with broad white tips, outermost pair with as much white as black; chin and throat metallic green with violet reflections, purple on upper breast; yellow below, brightest on breast; underwing white, underwing-coverts at wing margin black with white tips; iris dark chestnut; bill and legs black. Female is slightly smaller than male, lacks metallic coloration on throat and side of neck, which have scaly appearance (owing to dark feather bases); breast and belly pale yellow. Juvenile is similar to female but lacking yellow; immature male has chin and throat dark grey with yellow mottling, breast and belly pale yellow. Voice. Song a 2-minute burst of fast ascending and descending short high-pitched notes of varied sounds such as “tsee”, “ti”, “to”, “wee”, “tzeee” and “tsuuee”. Calls similar to song notes, including “tsee-ee”, “bzueeh”, “jit-jit-jit” and “bink”. Young begging call “bjuit, bjuit, bjui”.

Habitat. Forests, particularly mossy montane primary forest, also woods, savanna woodland, gardens and plantations; to 1800 m.
Food and Feeding. Insects, spiders (Araneae) and nectar. Forages in pairs or small groups, sometimes in larger groups of up to 30 individuals; also joins mixed-species parties. Active feeder in treetops. Attracted particularly to *Canna* flowers.
Breeding. Egg-laying in Aug–Feb. Possibly a co-operative breeder; group of four, including one male, seen to investigate old nest. Singing male stands erect, turns one way and then other, and raises and vibrates wings to display white underwing-coverts; up to five males may sing and display together. Nest, built by female, a pouch-like structure, entrance with porch at side near top, dangling “beard”, made of leaves, moss and other plant material, lined with feathers, plant down and wool, hung from low branch. Clutch 2 eggs, grey-white, densely covered with small violet spots; no information on incubation and nestling periods. Nests parasitized by African Emerald Cuckoo (*Chrysococcyx cupreus*).
Movements. Possibly some altitudinal movement; reportedly absent from gardens at low levels in Apr.
Status and Conservation. Not globally threatened. Restricted-range species: present in São Tomé EBA. Common in all habitats with tall trees. Absent from N savannas.

Bibliography. Amadon (1953), Atkinson, Dutton *et al.* (1994), Atkinson, Peet & Alexander (1991), Bannerman (1948, 1951), Borrow & Demey (2001), Cheke & Mann (2001), Christy & Clarke (1998), Eccles (1988), Fry *et al.* (2000), Jones & Tye (2006), King & Dallimer (2003), de Naurois (1979, 1994), Snow (1950).

Genus *DREPTES* Reichenow, 1914

26. Sao Tome Sunbird

Dreptes thomensis

French: Souimanga de Sao Tomé **German:** Riesennektarvogel **Spanish:** Suimanga Gigante
Other common names: (São Tomé) Giant Sunbird, Dusky São Tomé Sunbird

Taxonomy. *Nectarinia thomensis* Bocage, 1889, São Miguel, São Tomé, Gulf of Guinea.
Genus previously merged with *Nectarinia*. Monotypic.
Distribution. São Tomé, in Gulf of Guinea.

Descriptive notes. Male 20–23 cm, 21–28 g; female 18–19 cm, 18–21 g. Unmistakable; the largest sunbird, with all-blackish plumage, long decurved bill, and long graduated tail (outer rectrix 28–48 mm shorter than central pair). Male has head and upperparts black, feathers edged slightly metallic steel-blue, greayer on rump; uppertail-coverts and lesser and median upperwing-coverts tipped metallic blue; remiges dark brown; tail black, tinged dark blue, outer three feather pairs tipped white; dark brown below, feathers tipped metallic blue, belly to vent with yellow wash; pale grey-buff underwing-coverts and axillaries tipped white; iris dark brown or red; bill and legs black. Female is like male but smaller, wing length 79–84 cm (male 85–94 cm), tail 69–76 cm (male 84–98 cm). Juvenile resembles a small adult. Voice. Song a series of 3 notes each 1 second long, “chee-cheep-eeep” or “tsweet-chut-uu” or “huët-tsip-tsuit”, often followed by “chut, chut, chit chit”. Call a loud “cheep”. Lekking males call “tic-tic-tic-tic-tic-tic”, followed by “tsi-tsu-huee, tsi-tsiu-tsiu” or “huit-huit-rruit-rruit”.

Habitat. Montane forest, including mistforest, also lowland primary forest and plantations; also strays into disturbed habitats up to 1 km from forest. Lowlands to c. 2000 m.
Food and Feeding. Insects; also nectar and fruit pulp. Forages for insects on leaves, and hovers to feed from beneath leaves; probes flowers and bark in canopy.
Breeding. Egg-laying Sept–Jan. Possibly polygynous; females outnumber males by factor of 2 at some localities. Apparent lekking behaviour recorded, several males gathering together to sing. Nest a pouch, with side entrance and small porch, made of moss and other plant material, with long dangling “beard”, suspended 4–10 m above ground from end of long branch. Clutch 2 eggs, elongate, white with small red spots. No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in São Tomé EBA. Rare to locally common. Global population in range 250–999 individuals, and believed stable; extent of available habitat estimated at 340 km². Threatened by forest clearance. Large areas of lowland and middle-altitude forest already lost to plantations, and number of small farms has increased and tree-cutting accelerated as a result of land privatization. Clearance of forest for cultivation, timber and fuelwood an additional threat; likewise, road-building developments along E & W coasts have allowed increased human access to previously remote areas. Proposals made to designate pri-

mary forests as ecological zones or national parks, but forest currently unprotected; law providing for listing of protected areas and for protection of threatened species has still to be ratified.
Bibliography. Amadon (1953), Anon. (2007f), Atkinson, Dutton *et al.* (1994), Atkinson, Peet & Alexander (1991), Bannerman (1948, 1951), Borrow & Demey (2001), Butchart & Stattersfield (2004), Cheke & Mann (2001), Christy & Clarke (1998), Fry *et al.* (2000), Jones & Tye (1988, 2006), King & Dallimer (2003), de Naurois (1983, 1994), Sargeant (1994), Snow (1950), Stattersfield & Capper (2000).

Genus *ANTHOBAPHES* Cabanis, 1851

27. Orange-breasted Sunbird

Anthobaphes violacea

French: Souimanga orangé **German:** Goldbrust-Nektarvogel **Spanish:** Suimanga Pechinaranja
Other common names: Violet-headed/Wedge-tailed Sunbird

Taxonomy. *Certhia violacea* Linnaeus, 1766, Cape of Good Hope, South Africa.
Genus previously subsumed in *Nectarinia*. Monotypic.
Distribution. Western Cape and SW Eastern Cape (E to Port Elizabeth), in SW South Africa.

Descriptive notes. Male 14.5–16.5 cm, 9–11.3 g; female 12.5–13.5 cm, 8.6–9.7 g. Male is iridescent green on head to mantle and chin to upper breast; back yellow-green, lesser upperwing-coverts metallic green, median and greater wing-coverts and flight-feathers brown, edged yellow-green; tail brownish-black, central pair of feathers elongated and darker, outer rectrices paler; violet breastband separating metallic green of throat from reddish-orange of upper breast and belly, yellow lower belly, pectoral tufts bright yellow; axillaries and underwing-coverts grey-brown; iris dark brown; bill and legs black. Female lacks metallic colours and elongated central rectrices, has head grey-olive, upperparts dark yellow-green, paler on rump and uppertail-coverts, tail brown, edged yellow, throat and breast dark yellow-green with some admixed grey, rest of underparts yellowish. Juvenile is like female but darker. Voice. Song a high-pitched warbling of melodious notes, interrupted at varying intervals by descending “tzzurr” or “jeeeu”. Calls include “seep-seep, seep-seep, seep-seep”, or “shraynk”; warning call “eet-eet” or “dzeeu-dzeeu”; males chasing one another give “ke-ke-ke” call.

Habitat. Fynbos; mountain slopes with heaths (Ericaceae) and proteas (*Protea*), also gardens, and occasionally in Karoo biome.

Food and Feeding. Nectar; also insects, including beetles (Coleoptera), flies (Diptera), Hymenoptera, Lepidoptera and Orthoptera; also spiders (Araneae). Known foodplants include 66 species of *Erica*, *Liparia splendens*, *Protea lepidocarpodendron* and *Protea mellifera*. Forages singly, in pairs and in small groups; in non-breeding season forms loose groups of 50–100 individuals. Hawks for insects; feeds also on ground.

Breeding. Egg-laying in all months, with peak May–Aug (breeds in synchrony with flowering of *Erica* species); two or three broods. Territorial display by male, from protea or *Erica* bush, includes wing-stretching to reveal pectoral tufts and tail-jerking. Nest built by female alone, taking 5–18 days, an ovoid structure without porch or “beard”, 85–120 mm high, 64–90 mm wide, 75–100 mm deep, side entrance 2–4 cm wide, made of twigs, roots, *Erica* leaves and grass, held together by cobwebs, lined with down from protea or *Eriocephalus* species, occasionally adorned externally with spider cocoons and feathers, placed low down (76% below 1 m) but sometimes up to 10 m above ground in bush (e.g. protea). Clutch 1–2 eggs, colour variable, usually white, sometimes green-grey, densely spotted and streaked with grey-brown or chocolate-brown, markings concentrated at wider end; incubation by female, period 14–15 days; chicks brooded by female, fed by both sexes, male providing one-third of feeds, nestling period 15–22 days; young at least partly dependent on parents for c. 3 weeks after leaving nest. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*). In one study, hatching rate 65% and fledging rate of nestlings 68%.

Movements. During austral summer, moves up to 8 km, and ascends at least 320 m higher, in search of flowering plants. Vagrant recorded once in King William’s Town (S Eastern Cape), outside normal range.

Status and Conservation. Not globally threatened. Restricted-range species: present in Cape Fynbos EBA. Common to locally uncommon. Habitat loss has presumably caused some declines. Habitat disturbance by humans and invasive plants a potential threat in some areas. Occurs in Kirstenbosch Botanical Gardens.

Bibliography. Broekhuysen (1963), Cheke & Mann (2001), Collins (1983b, 1983c), Fraser (1989, 1997c), Fraser & McMahon (1991, 1992), Fraser *et al.* (1989), Fry *et al.* (2000), Hall & Moreau (1970), Hockey *et al.* (2005), Oatley (1997), Siegfried *et al.* (1985), Shead (1967), Spottiswoode (1993), Williams (1993a, 1993b), Winterbottom (1964), Wooler (1982).

Genus *CYANOMITRA* Reichenbach, 1853

28. Green-headed Sunbird

Cyanomitra verticalis

French: Souimanga à tête verte **German:** Grünkopf-Nektarvogel **Spanish:** Suimanga Cabeciverde
Other common names: Green-headed Olive/Olive-backed Sunbird(!)

Taxonomy. *Certhia verticalis* Latham, 1790, Africa = Senegal.
Genus formerly subsumed in *Nectarinia*. Has been thought to form a superspecies with *C. bannermani*, possibly including also *C. oritis* and *C. alinae*. Nominate race and *bohndorffi* intergrade in Cameroon. Proposed race *niassae*, described from Kondeland (N of L Malawi), in SW Tanzania, appears indistinguishable from *viridisplendens*. Four subspecies recognized.

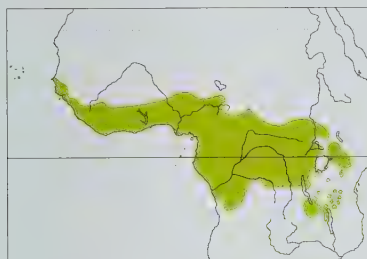

Subspecies and Distribution.

C. v. verticalis (Latham, 1790) – Senegal E to W & N Cameroon.

C. v. bohndorffi (Reichenow, 1887) – C & S Cameroon and Central African Republic S to inland Gabon, middle DRCongo and N Angola.

C. v. cyanocephala (Shaw, 1811) – coasts of mainland Equatorial Guinea and Gabon S to NW Angola (Cabinda) and extreme W DRCongo (mouth of R Congo).

C. v. viridisplendens (Reichenow, 1892) – S Sudan and NE & E DRCongo E to Uganda, Kenya (E to Mt Kenya) and Tanzania, and NE Zambia and N Malawi.

Descriptive notes. 13–14.5 cm; male 9.7–15.5 g, female 10.7–15.5 g. Male nominate race has head, nape, throat and upper breast metallic green with blue reflections, lores black, upperparts behind nape olive with gold tinge; underparts and tail brown edged olive yellow, golden-olive on outer webs of lesser wing-coverts and edges of greater coverts; underparts grey, pectoral tufts creamy with yellow wash, tips of flank feathers green-yellow, axillaries and underwing-coverts grey; iris dark brown; bill and legs greenish-black. Female differs from male in having metallic colour greener and only on forehead, crown, ear-coverts and nape, with

throat grey, no pectoral tufts, and axillaries and underwing-coverts white. Immature male has forehead and crown grey (slightly mottled), chin, throat, lores and malar region blackish-grey, yellow wash on underparts; immature female has paler grey throat. Race *bohndorffi* is bigger than nominate (male wing 64–70 mm; nominate 60–65 mm), with greener, less olive, upperparts and darker grey underside, immature has whole crown dull black and contrasting with olive back; *cyanocephala* is similar to previous in size, but throat and breast more purplish and belly sootier grey, has back darker and greener olive than nominate; *viridisplendens* has head and throat brighter green, less bluish, than other races. **VOICE.** Song a repetition of “tsk” every 1–5 seconds, then a rapid burst of 5–11 “tse” notes. Calls include single “tsk”, also plaintive “chi-u-wee”, “chee”, “tchoue” and “cheerick”; “t’chew-ee, t’chew-ee” used by birds arriving at feeding stations; alarm call “chaa” or “pss-chaa”; aggressive calls include sharp “chep-pee-pee-pee-pee”, sometimes leading into trilling “tee-tee-tee”, and during head-up display “peeeeee-tew” (rising in pitch, dropping on last note). May mimic other species.

Habitat. Primary, secondary and gallery forests and clearings within them, also forest–savanna mosaic and well-wooded savanna and coastal habitats, including mangroves, plantations; also gardens. Occurs at up to 3000 m in Sudan, to 2400 m in E African highlands, 2500 m in Rwanda and 2150 m in Zambia.

Food and Feeding. Nectar and other vegetable matter; arthropods. Nectar taken from variety of tree species and mistletoes (Loranthaceae); small fruits, seeds and sap from oil palms (*Elaeis guineensis*) also eaten. Insect prey includes beetles (Coleoptera), flies (Diptera), homopteran bugs, Hymenoptera and small Orthoptera; spiders (Araneae) also taken. Usually forages high in canopy, sometimes on trunks of trees, but also at lower levels, especially in shaded parts. Gleans leaves; hover-gleans, and chases insects in flight. Groups of up to 30 males forage among fruiting *Xylopia aethiopica* trees, each individual defending a feeding area of 2–4 m around itself by singing and aggressive displays of pectoral tufts.

Breeding. Laying Aug–Sept in Sierra Leone, Jul in Nigeria, Mar–Apr, Jun–Jul and Sept–Oct in Cameroon, Nov–Dec in Gabon, Sept in DRCongo, Feb and probably Mar and Apr in DRCongo, Jan–Nov in E Africa, Dec–May in Zambia, and Dec–Feb and Apr in Malawi; bird in breeding condition in Feb in Angola. Nest an untidy ball with side entrance, made of dried grass, leaves and bark fibres, held together without cobwebs, lined with banana bark and fibres, some with “beard” hanging 0.5 m down from entrance, suspended 1.5–12 m up in vegetation, sometimes over water; territory 0.5–10 ha within forest, one defended by same pair for three seasons. Clutch 2 eggs, matt, slightly pointed at sharp end, pale pink background covered with chocolate-brown dots and lines and grey markings; chicks fed by both parents; no information on duration of incubation and nestling periods. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*).

Movements. No data.

Status and Conservation. Not globally threatened. Common over most of its range; uncommon in Gambia and Senegal. Found at densities of 12–20 pairs/km² in Gabon. Occurs in a number of national parks and other protected areas.

Bibliography. Baker & Baker (2007), Bannerman (1948), Blancou (1939), Borrow & Deme (2001), Brosset & Érad (1986), Carroll (1988), Chapin (1954), Cheke (1978), Cheke & Mann (2001), Dowsett-Lemaire (1989a, 1989b, 1990), Eisentraut (1963), Fry *et al.* (2000), Hall & Moreau (1970), Kramer (1975), Kunkel (1964), Lewis & Pomeroy (1989), Louette (1987), Lynes (1938), McCarthy (2006), Ng’weno (1990), Nikolaus (1987), Rand *et al.* (1959), Short & Horne (2003), Zimmerman *et al.* (1996).

29. Bannerman’s Sunbird

Cyanomitra bannermani

French: Souimanga de Bannerman

Spanish: Suimanga de Bannerman

German: Bannermannektarvogel

Other common names: (Bannerman’s) Blue-headed Sunbird

Taxonomy. *Cyanomitra verticalis bannermani* C. H. B. Grant and Mackworth-Praed, 1943, Kayoyo, Katanga, southern DRCongo.

Genus formerly subsumed in *Nectarinia*. Has been thought to form a superspecies with *C. verticalis*, possibly including also *C. oritis* and *C. alinae*. Specific name *sororia*, based on a specimen from Calandula (Malanje), in N Angola, is a synonym of present name. Monotypic.

Distribution. N, W & E Angola, S DRCongo (Katanga) and NW Zambia.

Descriptive notes. 13 cm; 14 g. Male has metallic greenish-blue hood covering head, neck and chin to upper breast, with violet reflections on throat and upper breast; upperparts olive-green, remiges and rectrices dark grey-brown, primary coverts and alula edged olive-green, yellowish edges of primaries and outer webs of all except outermost rectrices; underparts grey, darker on lower breast and upper flanks, pectoral tufts pale yellow, underwing pale grey; iris dark reddish-brown; bill and legs black. Distinguished from *C. verticalis* by duller metallic blue chin and throat with green reflections, paler grey chest and belly, smaller and less promi-

nent pectoral tufts, and shorter, straighter bill. Female has crown dark brown, edged dark grey, sometimes with dull metallic light green edges, particularly on side of crown (appearing mottled), neck and chin to chest smoke-grey, otherwise similar to male but brighter above. Immature male resembles female, but darker grey throat and very little metallic green on forehead, bright olive-green above. **VOICE.** Song a sequence of c. 5 “chuk” notes before “purz-urr-wee” wheeze. Call “chuk”. **Habitat.** Riverine forest and moist evergreen forest, sometimes entering miombo woodland.

Food and Feeding. Few data. Nectar, termites (Isoptera) and spiders (Araneae) recorded as eaten.

Breeding. Egg-laying in Sept in Zambia. Only known nest was big, 18 cm tall (from point of attachment to base), 10 cm wide and 9 cm deep (but extra material made nest up to 19 cm broad), side entrance with porch of thin stems, made of long coarse grass stems, roof of black fibrous stems, lining of fine stems, much material hanging down to 16 cm below base, nest adorned externally with strips of banana bark and large leaves, suspended 1.2 m over water from vine. Clutch 2 eggs, matt pink-brown, densely streaked with dark purple-brown. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Uncommon in Angola; not uncommon elsewhere in range.

Bibliography. Benson *et al.* (1971), Cheke & Mann (2001), Colebrook-Robjent (1990), Dean (2000), Dowsett *et al.* (2008), Fry *et al.* (2000), Grant & Mackworth-Praed (1943a), Hall & Moreau (1970), Louette (1987), Ripley (1960, 1962), Traylor (1962).

30. Blue-throated Brown Sunbird

Cyanomitra cyanolaema

French: Souimanga à gorge bleue

German: Braunrücken-Nektarvogel

Spanish: Suimanga Gortjazul

Other common names: Blue-headed Brown/Blue-throated Sunbird

Taxonomy. *N.[ectarinia] cyanolaemus* Jardine and Fraser, 1851, Malabo, Bioko.

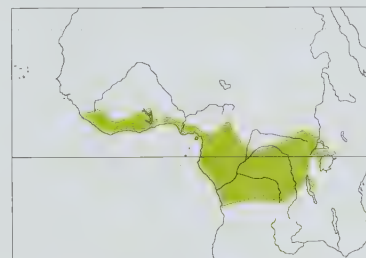

No apparent close relative; shows characters of both present genus and *Chalcomitra*. Three subspecies recognized.

Subspecies and Distribution.

C. c. magnirostrata (Bates, 1930) – Sierra Leone E to Togo.

C. c. octaviae Amadon, 1953 – SW Nigeria, Cameroon and S Central African Republic E to Uganda (Budongo Forest) and W Kenya (Kakamega Forest), and S to N Angola and S DRCongo (Katanga); also NW & W Tanzania.

C. c. cyanolaema (Jardine & Fraser, 1851) – Bioko I (Fernando Póo).

Descriptive notes. 14–15 cm; 11–20 g. Male nominate race has forehead, chin and throat metallic dark steely blue-green, tinged violet; crown, side of head and upperparts brown, flight-feathers and tail also brown, some rectrices tipped pale; underparts mostly brown, belly, flanks and undertail-coverts paler grey-brown, pectoral tufts lemon-yellow or creamy, underwing greyish; iris dark brown; bill and legs black, soles of feet yellowish. Female is dark brown with olive-yellow wash above, white eye-brow and feathers surrounding eye, brown wing and tail feathers edged olive-yellow, edges broadest on secondaries, some tail feathers with

pale tips, chin and throat white or buff, underparts grey-white and variously mottled with pale yellow-green and grey, brightest yellow on vent, white underwing; bare parts as male. Juvenile male lacks pectoral tufts and metallic coloration, has yellowish-olive edges on wing and tail feathers, underparts tinged olive, upper mandible greenish-black, lower mandible yellow with greenish-black tip; juvenile female has grey-brown underparts faintly washed yellow. Race *magnirostrata* has relatively bulky and long bill (24–28 mm), male darker above than nominate; *octaviae* has smaller bill (20–25.5 mm) than previous and male is greyer, less brown, below, female yellow-tinged, less green, above than nominate. **VOICE.** Song an extended series of descending trills and twitters involving “ptisew” and “psit” notes. Calls include “tschuk”, “tsit”, “chip”, and ascending and descending “tsesw”.

Habitat. Forest, open areas (e.g. gardens, cultivations) within forest, and gallery forest in savanna; various habitats along coast. To 1500 m in Liberia, Uganda and Kenya, and to 2000 m in Rwanda.

Food and Feeding. Takes insects, spiders (Araneae), also seeds and small fruits (e.g. of *Alchornea* and *Discoglypemma*). Forages at varying heights, from ground level to 45 m. Joins mixed-species flocks with other sunbirds. Attends flowers of mistletoes (Loranthaceae) and of trees, including *Symphonia glubulifera* and those of genera *Albizia*, *Berlinia*, *Bombax*, *Caesalpinia*, *Combretum*, *Erythrina*, *Maranthes*, *Musanga*, *Spathodea*.

Breeding. Laying in Aug and Nov in Nigeria, Jun and Jul in Cameroon, Dec–Apr in Gabon, Oct in DRCongo, Mar in DRCongo, and Mar–Sept in Uganda; birds in breeding condition in Aug–Sept in N Angola (Cabinda). At start of rains, males gather in leks of 4–45 individuals on dead branches, display by exposing pectoral tufts and hopping from branch to branch opposite each other, singing with puffed-up chest, head thrown back, bill wide open, wings drooping and tail spread. Nest an extraordinary elongated structure up to 1 m from top to bottom, with short porch above entrance hole, built of twigs, dead leaves, *Marasmius* fungus, cobwebs, fibres and moss, with deep inner chamber lined with bark or mammal hairs, including those of gorilla (*Gorilla gorilla*), suspended 1–12 m up on shrub or bush in clearing or over water. Clutch 2 eggs, matt, variously pink-brown, brown, cream, grey-violet or buff, grey around larger end, densely marked with brown or dark purple-grey; incubation by female, period 14 days; no information on nestling period.

Movements. Mostly sedentary; records in gallery forest in savanna lands primarily in wet season, suggesting seasonal dispersal.

Status and Conservation. Not globally threatened. Common in most of W Africa, but rare in Togo; widespread and common in mainland Equatorial Guinea, and locally common in Angola, DRCongo, Uganda and Tanzania. Occurs in several protected areas, e.g. Korup National Park, in Cameroon.

Bibliography. Amadon (1953), Bates (1911, 1927), Borrow & Deme (2001), Brosset (1974), Brosset & Érad (1986), Burger (1987), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire (1990), Fry *et al.* (2000), Hall & Moreau (1970), Lachenaud (2006b), Mariaux & Vaucher (1991), Prigogine (1971, 1972), Rand *et al.* (1959), Traylor & Parelius (1967).

31. Cameroonian Sunbird

Cyanomitra oritis

French: Souimanga à tête bleue

German: Blaukopf-Nektarvogel

Spanish: Suimanga Camerunés

Other common names: (Cameroon) Blue-headed Sunbird(!)

Taxonomy. *Cinnyris oritis* Reichenow, 1892, Buea, 950 m, Mount Cameroon, Cameroon. Genus formerly subsumed in *Nectarinia*. Has been thought to be possibly part of a superspecies formed by *C. verticalis*, *C. bannermani* and *C. alinae*. Three subspecies recognized.

Subspecies and Distribution.

C. o. hansoensis Bannerman, 1922 – SE Nigeria (Obudu Plateau and Mambilla Plateau) and highlands of W Cameroon (except Mt Cameroon).

C. o. oritis (Reichenow, 1892) – Mt Cameroon (SW Cameroon).

C. o. poensis Alexander, 1903 – Bioko I (Fernando Poo).

hansoensis is smaller than others, has shorter bill than nominate, metallic colour of feathers of crown and side of head bright steel-green (instead of dull steel-blue), throat and breast steel-blue (not deep purplish-blue), middle of belly more yellowish; *poensis* is slightly bigger than preceding race, shorter-billed and darker olive than nominate, with gloss on head more greenish and metallic colour extending to hindneck, side of neck and farther down breast. VOICE. Song consists of bursts of metallic notes and a quiet warble interspersed with up to four repeats of "tsi", each burst lasting 2–4 seconds. Calls include repetitive ticking, a "pseep" usually at intervals of half a second, and "tch-tch-tchwee" repeated every 2 seconds; alarm call "jeep".

Habitat. Undergrowth in forest, forest edges, and beside streams. On Mt Cameroon in montane forest at 1200–2100 m and eucalypt (*Eucalyptus*) plantations; strays down to 570–670 m in period Jun–Sept. Primary and secondary forest and clearings at 800–2800 m on Bioko.

Food and Feeding. Insects and nectar. Seen to feed at *Lea guineensis*, *Psychotria manni* and unidentified Rubiaceae. Forages singly or in pairs; sometimes large numbers assemble at flowering trees.

Breeding. Egg-laying in Mar–Apr, Jul and Nov–Dec in Cameroon and Apr on Bioko. Pear-shaped nest, with porch extending 5 cm above entrance, made of loose grass, rootlets and moss, lined with fibre and silk-cotton, with dry grass "beard", attached to fern 1 m up over rocky bank by stream. Clutch 2 eggs, thickly covered in dark brown speckles, darker at broad end. Nests recorded as parasitized by Klaas's Cuckoo (*Chrysococcyx klaas*). No other information.

Movements. Some altitudinal movement; descends to lower levels on Mt Cameroon, Jun–Sept.

Status and Conservation. Not globally threatened. Restricted-range species: present in Cameroon Mountains EBA. Common within its restricted range. Frequent in Gashaka-Gumti National Park (in Mambilla Plateau), in Nigeria. In Cameroon, reasonably common in Bamenda Highlands, Bakossi Mts, Rumpi Hills, Mt Manenguba, Mt Kupé and Mt Cameroon. Common on Bioko.

Bibliography. Bannerman (1948), Borrow & Demey (2001), Boulton & Rand (1952), Cheke & Mann (2001), Eisenraut (1963), Fry *et al.* (2000), Hall & Moreau (1970), Newsome (1986), Pérez del Val (1996), Serle (1965), Smith *et al.* (2000), Stuart & Jensen (1986).

32. Blue-headed Sunbird
Cyanomitra alinae

French: Souimanga d'Aline **German:** Ruwenzorinektarvogel **Spanish:** Suimanga Cabeciazul
Other common names: Rwenzori Blue-headed Sunbird

Taxonomy. *Cyanomitra alinae* F. J. Jackson, 1904, Rwenzori, DR Congo. Genus formerly subsumed in *Nectarinia*. Has been thought to be possibly part of a superspecies formed by *C. verticalis*, *C. bannermani* and *C. oritis*. Proposed race *vulcanorum* (described from W Kivu Volcanoes, in E DR Congo) considered a synonym of *tanganjicae*. Five subspecies recognized.

Subspecies and Distribution.

C. a. deroi (Prigogine, 1975) – NE DR Congo in two main populations (one W of L Albert, the other W of L Edward).

C. a. alinae F. J. Jackson, 1904 – NE DR Congo (W Rwenzori Mts, Virunga Volcanoes) and SW Uganda (E Rwenzoris, Bwindi Forest).

C. a. tanganjicae (Reichenow, 1915) – E DR Congo (mountains W of L Kivu, Itombwe Mts, NW of L Tanganyika), Rwanda (Nyungwe forest, SE of L Kivu) and Burundi.

C. a. kaboboensis (Prigogine, 1975) – Mt Kabobo, in E DR Congo.

C. a. marungensis (Prigogine, 1975) – Marungu Mts, in SE DR Congo.

dull olive-green lower flanks and undertail-coverts; underwing greyish-white; iris brown or reddish-brown; bill black; legs black or olive-black. Female is similar to male but has no pectoral tufts, and metallic feathers on crown duller green, without blue sheen. Juvenile male is dull olive-green above, with metallic spots on crown, orange-yellow tinge on mantle, has chin to upper breast dull blackish-grey with dark barring, rest of underparts greyish-olive. Race *deroi* has crown deep green, less blue than nominate, and metallic colour below bluer, less purple, also back darker and redder and breast darker grey than other races; *tanganjicae* has head greener, less blue, than nominate, longer bill than previous; *kaboboensis* differs from preceding two in having deep grey

belly only slightly tinged black (looking paler), also less olive in lower belly and undertail-coverts, no metallic green in wing-coverts, steel-blue neck and throat with greener reflections; *marungensis* is distinguished from last by paler belly and shorter and weaker bill. VOICE. Song a quiet twittering, culminating in a series of loud "chip" notes every 3–4 seconds; advertises territory with far-carrying rising and falling notes in series 3–6 seconds long. High-pitched subsong used in aggressive meetings and courtship. Calls include rising and falling sequence ending with distinctive "tci tci tci yehu", also "tsee" and "chip".

Habitat. Primary, secondary and riverine montane forests above 1400 m and up to 3280 m; 1980–2480 m on Mt Kabobo, and 1660–1710 m in Marungu Mts.

Food and Feeding. Insects and small spiders (Araneae); also nectar. Forages usually at low levels, but sometimes in canopy. Visits flowers of *Balthasarea schliebenii*, a favourite species around which it defends territories; feeds also from *Brillantasia*, *Canaria emini*, *Impatiens niarniamensis*, *Ixora burundensis*, *Lobelia giberroa*, *Phragmanthera usuiensis*, *Pseudosabicea*, *Symphonia*, *Tapinanthus brunneus* and *Tapinanthus constrictiflorus*. Takes nectar from flowers of trees and mistletoes (Loranthaceae) while perched, also while hovering.

Breeding. Egg-laying in Jan–May in DR Congo. Territorial males face each other on treetops, calling, until one flies at the other; occasionally both fall together, gripping each other's feet, before displays repeated. Nest pouch-shaped, entrance with pronounced porch, made of moss, *Usnea* lichens, grass, roots and dry leaves, lined with fine grass or flower heads, suspended 2 m up from bush. Clutch 1–2 eggs, red-brown or red-grey with dark patches, darker at larger end. No other information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Albertine Rift Mountains EBA. Common in most of its montane range; scarce in Kivu area of DR Congo.

Bibliography. Bennun (1986), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Dehn & Christiansen (2001), Dowsett & Prigogine (1974), Dowsett-Lemaire (1990), Fry *et al.* (2000), Hall & Moreau (1970), McCarthy (2006), Prigogine (1971, 1972, 1975, 1984), Schouteden (1938).

33. Eastern Olive Sunbird
Cyanomitra olivacea

French: Souimanga olivâtre **German:** Olivnektarvogel **Spanish:** Suimanga Oliváceo Oriental
Other common names: Olive/Olive-coloured Sunbird

Taxonomy. *Cinnyris olivaceus* A. Smith, 1840, Kafirland eastward toward Port Natal = Durban, South Africa. Genus formerly subsumed in *Nectarinia*. Probably forms a superspecies with *C. obscura*. Formerly regarded as conspecific, but separated initially on basis that females of latter lack pectoral tufts; although some female *C. obscura* do have pectoral tufts (albeit white, wispy insignificant ones), and conspecificity supported by analyses of mitochondrial DNA, treatment as separate species nevertheless considered justified, as the two differ in vocalizations and in egg patterning, and yellow pectoral tufts extremely rare (if they occur at all) in female *C. obscura*. Recent re-examination of specimens reveals that possibility of sympatry of the two species on Zanzibar is unfounded. Additional proposed races are *chyulu* (described from Chyulu Mts, in S Kenya), which is merged with *neglecta*, *puguensis* (Mafia I, off N Tanzania), synonymized with *changamwensis*, *intercalans* (Fort Jameson, in Eastern Province of Zambia), included in *alfredi*, and *daviesi* (Pondoland, in coastal E South Africa), considered indistinguishable from nominate. Five subspecies recognized.

Subspecies and Distribution.

C. o. changamwensis Mearns, 1910 – S Somalia and coastal SE Kenya and E Tanzania (inland to Taita, Usambaras, Pugu Hills and S Pare Mts), Zanzibar and Mafia I.

C. o. neglecta Neumann, 1900 – SC Kenya S to NE Tanzania.

C. o. alfredi Vincent, 1934 – S Tanzania, E Zambia, Malawi and N Mozambique.

C. o. olivacea (W. K. H. Peters, 1881) – coastal areas of SE Tanzania, Mozambique and NE South Africa (NE KwaZulu-Natal).

C. o. olivacea (A. Smith, 1840) – S KwaZulu-Natal S to NE Eastern Cape (Pondoland), in E South Africa.

yellowish-green; iris dark brown; bill and legs black. Sexes alike, but male (wing 61–70 mm, bill 27–29 mm) slightly bigger than female (wing 59–64 mm, bill 27–28 mm). Juvenile is olive-yellow from chin to chest, and brighter olive above than adult, bill grey, legs pale pinkish-grey. Race *alfredi* is greener than nominate, also paler below, and smaller (male wing 55–67 mm, bill 24–27 mm); *neglecta* is duller above, crown darker, and greyer below than previous; *changamwensis* has brighter and greener upperparts and paler underparts than last, greyish belly contrasting with greener upper breast and throat, also smaller (male wing 56–69 mm, bill 22–24 mm); *olivacea* is paler above and below, smaller (male wing 57–63 mm, bill 21–23 mm) than *alfredi* and with smaller and finer bill, lacks orange in pectoral tufts. VOICE. Song of nominate race a minute-long repetition of rising and falling whistling notes, with occasional melodic sequences of "tsee-tsee-tsee-, tseedlee, eedlee-id-id-seedlee, eedlee-ee-ee-ee"; also a slower warble of "see-weetee-wee-tee-to-tip" and "tsee-tsee-tsee..."; rival males may sing from a tree together in a "choir", with ascending and descending notes. Song of *alfredi* consists of falling notes, "dee-dee-dee-di-doo", also a lengthy series of "tschi" notes repeated every 0.5 seconds, mixed with short melodious sections and ending in repeats of "tsk". Calls include scolding "tsk-tsk-tsk" and "tsick" or "tut-tut-tut", a high-pitched "tseeng-tseeng-tseeng-tseeng", and stuttering "ch, ch, ch"; also "choyt", "chwp, chwp, chwp...", "chip.p.p.p.p", an insect-like "phit", "zeet" or "woot, zeet", or "wip-wip-wip-wip..." repeated again and again (sometimes as "mid-day" call); feeding areas defended with "phweep-phweep" call; alarm "tsink-tsink-tsink" or "jet-jet-jet" or harsh "tk".

Habitat. Forest and clearings, also dense woodland, thickets, coastal scrub, plantations and gardens; to 2150 m.

Food and Feeding. Takes insects, spiders (Araneae), berries, fruit and nectar. Feeds from flowers of trees (e.g. *Erythrina*, *Jacaranda*, *igelia africana*), mistletoes (Loranthaceae) and other plants,

such as *Fuchsia*, *Gardenia*, *Hibiscus*, *Leonotis* and *Strelitzia*. Mainly insectivorous, at least in Malawi. Forages singly or in groups of up to 100 individuals, and in mixed-species flocks. Feeds mainly in undergrowth and lower section of forest; sometimes higher, to canopy. Hovers in front of flowers, and searches along leaves. Gleans leaves; hawks for insects, and inspects spider webs.

Breeding. Laying recorded in Jun in Kenya, Dec–Jan in Tanzania, Sept–Apr on Zanzibar, Sept–Feb in Malawi, Nov in Mozambique, and Aug–Apr in South Africa. Probably polygynous. Singing males gather in leks of 10–20 individuals, which compete for highest perches; males conduct fluttering display-flights. Territorial. Nest, sometimes completed within just two days, an untidy pear-shaped bundle, side entrance with porch, dangling “beard” up to 70 cm long, made of dry grass, fibres, twigs, rootlets, lichen, moss and leaves, held together with cobwebs, cup lined with down, feathers and fine grass, suspended from branch 0.5–2 m up. Clutch 1–3 eggs, grey-white with small greyish-brown spots and streaks; incubation 12–15 days; nestlings fed by both sexes, fledging period 13–17 days. Nests sometimes parasitized by African Emerald Cuckoo (*Chrysococcyx cupreus*).

Movements. Mostly sedentary, but strays in search of food; may undertake post-breeding altitudinal movements. Longest ringing recovery at distance of 4 km.

Status and Conservation. Not globally threatened. Common in most of range; locally common in Malawi. In South Africa, recorded density of 5–7 pairs/ha in coastal areas of KwaZulu-Natal, but scarcer in inland areas. Occurs in several protected areas, including e.g. Arusha National Park, in Tanzania, and Lilongwe Nature Sanctuary, in Malawi.

Bibliography. Aspinwall (1971), Bannerman (1948), Bowie *et al.* (2004b), Cheke & Mann (2001), Clancey (1964, 1978a, 1994a), Dowsett-Lemaire (1989b), Dowsett-Lemaire & Dowsett (2006), Frost & Frost (1980), Fry *et al.* (2000), Hall & Moreau (1970), Hockey *et al.* (2005), Irwin (2004), Moreau & Moreau (1940), Sclater & Moreau (1933), Shead (1967), de Swardt (1992d), Swynnerton (1908), Tree (1997h).

34. Western Olive Sunbird
Cyanomitra obscura

French: Souimanga obscur **Spanish:** Suimanga Oliváceo Occidental
German: Einsiedel-Nektarvogel
Other common names: (Guinea/Guinean) Olive Sunbird

Taxonomy. *N[ectarinia] obscura* Jardine, 1843, Bioko. Genus formerly subsumed in *Nectarinia*. Probably forms a superspecies with *C. olivacea*. Formerly regarded as conspecific, but separated initially on basis that females lack pectoral tufts; although some females do have pectoral tufts (albeit white, wispy insignificant ones), and conspecificity supported by analyses of mitochondrial DNA, treatment as separate species nevertheless considered justified, as the two differ in vocalizations and in egg patterning, and yellow pectoral tufts extremely rare (if they occur at all) in female of present species. Recent re-examination of specimens reveals that possibility of sympatry of the two species on Zanzibar is unfounded. Races *guineensis* and *cephaelis* intergrade in Ghana–Togo region. Proposed races *vincenti* (described from Kapenguria, in W Kenya) and *lowei* (from R Kafuafuta, in W Zambia) considered insufficiently distinct from *ragazzii*. Race name *pembae* is a junior synonym of *granti*. Six subspecies recognized.

Subspecies and Distribution.

C. o. guineensis Bannerman, 1921 – Senegal E to Ghana and Togo.
C. o. cephaelis (Bates, 1930) – Ghana and Togo E to Central African Republic, S to N Angola; also Principe (in Gulf of Guinea); purportedly this race in Burundi.
C. o. obscura (Jardine, 1843) – Bioko I (Fernando Póo).
C. o. ragazzii (Salvadori, 1888) – E & SE DR Congo, extreme S Sudan E to C Ethiopia, Uganda, W Kenya, W Tanzania, Zambia and extreme N Malawi.
C. o. granti Vincent, 1934 – Pemba I, off NE Tanzania.
C. o. sclateri Vincent, 1934 – E Zimbabwe (Melssetter area) and bordering areas of Mozambique.

Descriptive notes. 13–15 cm; male 8–13.8 g, female 7.7–12.2 g. Male nominate race is olive-green above, darker on crown, with faint paler stripe over eye, buff area in front of eye, some white speckling on cheek and ear-coverts; upperwing and tail dark brown with olive-yellow edges; throat whitish, underparts greyish with yellowish tinge, richer yellow on belly, pectoral tufts lemon-yellow; underwing white, but axillaries yellowish; iris dark brown; bill greenish-black, basal half of lower mandible pale; legs brown, toes greenish-black. Female is as male but smaller, pectoral tufts absent or, if present, rudimentary and pale

whitish; bill black with basal half of lower mandible orange or light orange-brown, legs olive, feet yellowish posteriorly. Juvenile is darker olive with brownish crown, has chin and side of throat white, underparts yellowish with grey feather bases (appearing speckled). Race *guineensis* is smaller than nominate and darker below, with base of bill dark except for pale lower edge of upper mandible; *cephaelis* is somewhat longer-winged than previous, also paler, and with pale yellow base of lower mandible; *ragazzii* is similar in colour to nominate, but deeper green above and duller below, with pale yellow base of lower mandible; *granti* has straighter and shorter bill than nominate; *sclateri* is like nominate but paler below, chest with dusky fringes, outer two pairs of rectrices often with pale brownish-olive tips, juvenile has olivaceous throat and breast. **Voice.** Rival males may sing together. Song of nominate race a repeated “hoo-hoo-hoo”; of *guineensis* (in middle of day) a “chip” every 0.5 seconds or alternating high and low notes every second, “weep, wup, weep, wup”; song of *cephaelis* alternately rising and falling, and accelerating and decelerating, “pi, pi, pi, pi, pi-pi-pi, pi”, likened to sound made by squeaky wheel being cranked at different speeds. Calls include a harsh “tschaa-tscha-tscha”, uttered every 5 seconds; a “tic” note, “der-der-der” and “cooeo”.

Habitat. Variety of forest habitats, plantations, clearings, mangroves, coastal thickets, gardens and montane scrub.

Food and Feeding. Insects, spiders (Araneae), nectar, pollen, small berries, seeds, fruits and banana pulp. Visits flowers of various species, including e.g. *Carica papaya*, *Cieba pentandra*, *Oxyanthus troupinii*, *Symphonia globulifera*, *Syzgium congolense*, *Tecoma stans*, *Turraeanthus africanus* and mistletoes (Loranthaceae); seen also to exploit introduced garden plant *Justicia secunda* for nectar. Many trapped individuals have pollen, especially from banana plants, on forehead. Forages usually at low levels; may feed at up to 30 m up in forest canopy.

Breeding. Egg-laying recorded in Feb–Aug in Cameroon, Jan and Nov in Nigeria, Jan on Bioko, Nov–Jan on Principe, all months but mainly Jun–Sept in Gabon, Oct–Mar in Angola (but Aug–

Sept in Cabinda), Feb and Jun–Oct in DR Congo, Jun–Aug in Sudan, all months in E Africa (Feb, Apr–Jun, Aug and Sept in Uganda), and Sept–Mar in Zimbabwe. Males gather at leks of up to eight individuals, which display by singing, jumping, puffing up breast, exposing pectoral tufts, holding head high, with wings drooped and tail held up at 45-degree angle. Nest oval-shaped, side entrance with porch and long “beard” hanging from base of entrance, composed of moss, *Marasmius* fungus and spider webs, covered in grasses, leaves and stems, lined with seed down and soft fibres, suspended up to 5 m above ground from vegetation, sometimes over water. Clutch 1–3 eggs, variously grey or brown-grey, green or brown, heavily mottled with blotches of olive-grey, grey-green, violet-grey, yellow-brown or brown; incubation by female, chicks fed by both sexes; no information on duration of incubation and nestling periods. Nests parasitized by African Emerald Cuckoo (*Chrysococcyx cupreus*) and Klaas’s Cuckoo (*Chrysococcyx klaas*) and, in Gabon, by a honeyguide (of genus *Indicator*).

Movements. Mainly sedentary, but some altitudinal movements during droughts, and dispersal in search of food; immature dispersal suspected in Zimbabwe, where one recovery at 8 km from initial ringing site. In Cameroon, movements of 16 individuals recorded: 15 recaptured within 200 m of first capture, one at more than 300 m.

Status and Conservation. Not globally threatened. Common throughout most of range; locally very common to abundant. Density of 4 birds/ha in primary forest in Gabon. Occurs in several protected areas, e.g. Korup National Park, in Cameroon.

Bibliography. Akinpelu (1989), Bannerman (1948, 1951), Borrow & Demei (2001), Bowie *et al.* (2004b), Brosset & Éard (1986), Carroll (1988), Chabaud (1979), Chadder (2004), Chapin (1954), Cheke (1978), Cheke & Mann (2001), Clancey (1978a, 1978b, 1994a), Dranzoa (1997), Eiseutraut (1963), Fry *et al.* (2000), Hall & Moreau (1970), Hamner (1997, 2001), Irwin (2004), Jones & Tye (2006), Mann (1985), Mariaux & Vaucher (1991), Nikolaus (1987), Pérez del Val (1996), Prigogine (1971, 1972), Rand *et al.* (1959), Sammler (2007), Serle (1957), Tree (1997h), Tye & MacAulay (1993).

35. Mouse-coloured Sunbird
Cyanomitra veroxii

French: Souimanga murin **German:** Graunektarvogel **Spanish:** Suimanga Ratonil
Other common names: Grey/Verreaux’s Sunbird

Taxonomy. *Cinnyris veroxii* A. Smith, 1831, Cafferland = Eastern Cape Province, South Africa. Genus formerly subsumed in *Nectarinia*. Three subspecies recognized.

Subspecies and Distribution.

C. v. fischeri (Reichenow, 1880) – coastal lowlands from E & SE Somalia S to NE South Africa (NE KwaZulu-Natal), extending inland locally to S Malawi.
C. v. zanzibarica (Grote, 1932) – Zanzibar, off NE Tanzania.
C. v. veroxii (A. Smith, 1831) – coastal areas of E & S South Africa (E KwaZulu-Natal and E Eastern Cape Province; also isolated records from near Cape Town, in Western Cape).

Descriptive notes. 12–14 cm; male 8.5–18.8 g, female 7–16.6 g. Nominative race is dark brown with metallic blue-green sheen on crown and nape; mantle grey, rest of upperparts brownish-grey with metallic blue-green sheen (greener than on crown); side of face grey; remiges and greater upperwing-coverts dark brown with pale brown fringes, secondaries edged pale greenish, median and lesser wing-coverts broadly tipped metallic bluish-green; tail dark greyish-brown with green sheen, edged pale greyish-green, outermost rectrix and tip of adjacent one paler, inner borders of underside of rectrices greyish-white; chin to

breast pale buff or pale grey, rest of underparts greyish-olive or pale pinkish-grey, scarlet pectoral tufts; axillaries and underwing-coverts grey-white; iris dark brown; bill and legs black. Sexes alike, although female occasionally with some yellow in pectoral tufts. Juvenile has olive-green (not grey) mantle, white throat, yellowish-olive underparts brighter on breast than on belly, no pectoral tufts. Race *fischeri* is smaller than nominate (wing 60–63 mm; nominate 62–68 mm), also paler and greyer, less glossy, above, and paler below; *zanzibarica* is smaller (wing 59–61 mm), also paler (whiter) below than others, and greyer without metallic tinge above. **Voice.** Song characteristic, consists of repetitions every 2–5 seconds of 1-second bursts of descending “cherr-chip-chee-churruo” and variants. Subsong a fast series of “tserr-tserr” mixed with short melodious sections. Calls include “chip”, and “chip-chop”, also “tzeep-tjip-cha” and “sit, tsway-sit so”; alarm call various twitters e.g. “skirree, rirree, rirree...” and “tsink, tsink, tsink”.

Habitat. Mostly along coasts in forest, woodland, scrub, mangroves and gardens, straying inland into montane forest near coast. Found in deciduous and semi-evergreen thickets and forest and in riverine forest in Malawi.

Food and Feeding. Insects, spiders (Araneae), spider eggs; also nectar. Nectar taken from aloes (*Aloe*), *Erythrina*, *Halleria lucida*, *Kigelia africana*, *Leonotis leonurus*, *Mimusops caffra*, *Scadoxus punicea*, *Schotia afra*, *Strelitzia nicolai* and mistletoes (Loranthaceae). Forages mainly in higher strata of forest. Probes in flowers and mistletoe bunches. Hovers at spider webs to take prey; also hawks insects in flight.

Breeding. Egg-laying in May–Jul, Sept and Nov–Dec in Kenya, Jan, Apr and Dec in Tanzania, and Sept–Feb in South Africa. Displaying male thrusts head and neck up and fans wings; males display to each other in sessions for 30 minutes or more. Nest a long pouch, with extensive porch above side entrance, and often with hanging “beard”, often made of *Marasmius* fungal hyphae, otherwise rootlets, twigs, leaves, bark, down, moss, lichen or grass used, and (in absence of *Marasmius*) cobwebs used for holding nest together, exterior adornments of bark, web, leaves etc., thickly lined with fine grass on top of leaves, attached 1–6 m up in forest vegetation or in house or hut. Clutch 1–3 eggs, grey-white, buff or dark brown, darker at broader end, occasionally with grey-brown or red-brown spots and streaks; no information on incubation and nestling periods.

Movements. Some seasonal movements from forest to acacia (*Acacia*) woodland; occasional irruptions to W of usual range in South Africa.

Status and Conservation. Not globally threatened. Rare in Somalia; rare in Malawi range except in Lengwe National Park, where common. Scarce in Kenya, Tanzania and Mozambique, but race *zanzibarica* common in coral-rag bush on Zanzibar. Not uncommon in South Africa along coasts of KwaZulu-Natal and Eastern Cape.

Bibliography. PLATE 11

inches 3
 cm 8

Genus *CHALCOMITRA* Reichenbach, 1853

36. Buff-throated Sunbird

Chalcomitra adelberti

French: Souimanga à gorge rousse **Spanish:** Suimanga Gorjiclaro
German: Fahlkehl-Glanzköpfchen

Taxonomy. *Cinnyris adelberti* Gervais, 1833, Senegal; ?error = Sierra Leone. Genus previously merged with *Nectarinia*. Has sometimes been thought to form a superspecies with *C. rubescens*; alternatively, considered by others possibly closer to *C. senegalensis*. Two subspecies recognized.

Subspecies and Distribution.

C. a. adelberti (Gervais, 1833) – NW Guinea, and Sierra Leone E to Ghana and WC Togo.
C. a. eboensis (Jardine, 1843) – E Benin E to SE Nigeria and W border of Cameroon.

Descriptive notes. 11.5–12 cm; 8.3–11 g. Male nominate race has forehead and crown bright metallic green, back of head and neck blackish-brown, becoming paler on mantle and back; uppertail-coverts and tail blackish-brown; upperwing and wing-coverts dark brown with narrow chestnut edges, except for light chestnut lesser wing-coverts; chin and upper throat black, metallic green malar stripe; lower throat pale buff, forming bib, which is delineated from bright chestnut underparts by black band; underwing chestnut; brown of back and bib subject to bleaching, thus paler with time lapse since previous moult; iris brown; bill and legs

black. Female is olive-brown above, wings and tail darker brown, has throat greyish-white with olive-brown streaks, underparts cream-coloured, tinged and slightly streaked with olive. Immature male is like female, but more olive-brown below. Race *eboensis* male has paler throat and darker chestnut, less rufous, on underparts than nominate, female underparts paler, breast paler yellowish-grey with pale brown markings. **VOICE.** Song of nominate race a complex twittering c. 15 seconds long followed by “pttiooooo” calls every 1–3 seconds for more than a minute, also “tserr-pit-cherr-chooo” lasting 1.5–2 seconds, repeated every 4–6 seconds; song of *eboensis* repetitions of loud “tseep”. Various chirping calls, e.g. “chip”, “tseep”, “pitchew” or “pitchew-tweet”.

Habitat. Lowland forest and forest clearings; often near human habitation, when occurs in plantations and gardens. Below 1000 m.

Food and Feeding. Insects, spiders (Araneae), and nectar. Visits mistletoes (Loranthaceae) and flowers of such trees as *Albizia*, *Bombax*, figs (*Ficus*), *Spathodea campanulata*, *Tabebuia rosea*, *Parkia filicoidea* and *Symphonia*, and garden flowers such as *Hibiscus* and *Convolvulus*. Joins mixed-species groups with other sunbirds. Forages on branches in middle and upper strata of trees. Leaf-gleans, hovers below leaves and arboreal ant (Formicidae) nests; sallies from perches to take insects and spiders.

Breeding. Nests in Oct–Mar dry season. Singing male performs display-flights likened to butterfly flight. Untidy nest made of grass and dry leaves, entrance with short porch, with “beard” of fibres and/or spider webs, lined with white kapok, suspended 2–5 m above ground in mango tree (*Mangifera indica*) or *Raphia* palm. Clutch 1–4 eggs; both parents feed nestlings and remove faecal pellets. No other information.

Movements. Disperses S in search of flowers in dry season in Liberia and Nigeria.

Status and Conservation. Not globally threatened. Generally uncommon or locally common throughout range.

Bibliography. Bannerman (1948), Borrow & Demey (2001), Button (1967), Cheke & Mann (2001), Dellinger & Haeflner (1991), Dowsett-Lemaire & Dowsett (2007), Fry (1965), Fry *et al.* (2000), Gatter (1997), Gray (1972), Hall & Moreau (1970), Kraus (1986a), Lachenaud (2006b), Louette (1982), McCarthy (2006), Prinzing & Jackel (1986), Prinzing *et al.* (1989), Serle (1957), Turner & Forbes-Watson (1979).

37. Carmelite Sunbird

Chalcomitra fuliginosa

French: Souimanga carmelite **German:** Karmelglanzköpfchen **Spanish:** Suimanga Carmelita

Taxonomy. *C[erthia] fuliginosa* Shaw, 1811, Malembo, Cabinda, Angola.

Genus previously merged with *Nectarinia*. Forms a group with *C. rubescens* and *C. amethystina*; sometimes thought to form a superspecies with those, despite considerable geographical overlap, but all appear to hybridize occasionally in areas where they meet. Proposed races *nigrescens* (described from Brazzaville, in PR Congo), males of which have supposedly darker mantle, is treated as a synonym of nominate, but some authors have recommended its recognition for populations along lower R Congo. Two subspecies recognized.

Subspecies and Distribution.

C. f. aurea (Lesson, 1847) – coasts from Sierra Leone E to Gabon and PR Congo.
C. f. fuliginosa (Shaw, 1811) – NW Angola (including Cabinda) and lower R Congo (inland to Kwamouth, DR Congo).

Descriptive notes. 13–14 cm; 11.6–12.2 g. Male nominate race has body plumage chocolate-brown, darkest on breast, belly and undertail-coverts, except for metallic purplish-blue forehead and metallic violet chin, throat and uppertail-coverts, and small patch of metallic violet on lesser wing-coverts below carpal joint; remiges and rectrices very dark chocolate-brown; lemon-yellow pectoral tufts, dark brown underwing; some bleached individuals have back of head pale brown to grey-white, and light brown mantle; iris dark brown; bill and legs black. Female is earth-brown above, remiges and rectrices dark brown, upperwing-coverts edged and tipped pale buff, white tips on tail; moustachial stripe creamy buff, throat brownish, underparts creamy white with dark feather-centres (looking mottled). Juvenile male resembles female, but has sooty-brown cheeks, chin and throat, no moustachial stripe, and breast with heavy dark brown mottling. Race *aurea* is somewhat

less dark above than nominate, male with less extensive gloss on forehead and throat, female paler especially on neck and upper mantle. **VOICE.** Song a 0.5-second “pttreeeee”, repeated every 2–3 seconds, and a trilling “dree-dree”. Call “tsit”. **Habitat.** Woods, plains, mangroves, swamps, plantations and gardens in coastal regions; reaches savanna in Liberia, extends 50 km inland in Nigeria, and occurs inland on R Congo. **Food and Feeding.** Nectar and insects. Feeds at *Ceiba pentandra*, *Delonix regia*, *Hibiscus*, *Moringa pterygosperma* and plantains (*Musa*). Forages singly and in small groups of up to eight individuals. Perches on and hovers at flowers, also stretches up to them from ground.

Breeding. Laying recorded in Sept–Nov in Cameroon, Jan–Feb, Jul and Dec in Gabon, Sept and Nov in Nigeria and Sept–Dec in PR Congo. Nest a small pouch, with short “beard”, constructed from leaves, moss and fibres, adorned with bark and lined with down, suspended 3 m up from rubber tree, avocado tree, *Anona senegalensis* or other shrub, or from wire on telegraph pole. Clutch 2 eggs, glossy, long and ovate, brown-white ground colour obscured by brown or lilac-grey markings, denser at wide end. No other information.

Movements. Disperses along coasts and strays inland.

Status and Conservation. Not globally threatened. Rare to locally common throughout range. Faces some threat, at least locally, from mangrove destruction.

Bibliography. Bannerman (1948, 1951), Borrow & Demey (2001), Bouet (1942), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire & Dowsett (1991), Fry *et al.* (2000), Hall & Moreau (1970), Louette (1989), McCarthy (2006), Rand *et al.* (1959).

38. Green-throated Sunbird

Chalcomitra rubescens

French: Souimanga à gorge verte **Spanish:** Suimanga Gorjiverde
German: Grünkehl-Glanzköpfchen

Taxonomy. *Cinnyris rubescens* Vieillot, 1819, “Kingdom of Congo and Cacongo” = Cabinda area of north-west Angola.

Genus previously merged with *Nectarinia*. Forms a group with *C. fuliginosa* and *C. amethystina*; sometimes thought to form a superspecies with those, despite considerable geographical overlap, but all appear to hybridize occasionally in areas where they meet. Alternatively, may form a superspecies with *C. adelberti*. Three subspecies recognized.

Subspecies and Distribution.

C. r. crossensis Serle, 1963 – extreme SE Nigeria and SW Cameroon (Mamfe and to W of Bamenda).
C. r. stangerii (Jardine, 1842) – Bioko I (Fernando Póo).
C. r. rubescens (Vieillot, 1819) – C & S Cameroon, SW, SE & N Central African Republic and S borders of Sudan S to N Angola, NW Zambia, S & E DR Congo, Uganda, W Kenya and NW Tanzania.

Descriptive notes. 12–13 cm; male 8–14 g, female 6.5–11 g. Male nominate race has narrow black band on front of forehead, merging into metallic green crown with blue reflections, this interrupted by 3-mm stripe of metallic violet reflections towards hindcrown; throat iridescent green with bright purple fringe below, iridescent bluish-green malar streak separated from throat patch by brown streak (1 mm wide); rest of plumage very dark brown with golden-bronze tinge; iris dark brown; bill and legs black. Female is earth-brown above, darkest on forehead, with yellowish supercilium, brown lores and ear-coverts, dark brown wings

and tail darker than back, remiges edged pale, rectrices narrowly tipped white; throat greyish-white or streaked brown (sometimes black), yellowish-white breast prominently streaked olive-brown, belly yellower and less markedly streaked, pale yellow undertail-coverts dark in middle, pale yellow axillaries and underwing-coverts mottled with greyish-brown and tipped white. Juvenile resembles female, but tinged olive above and yellower below, throat and breast mottled dusky brown, markings especially dense on throat, which may appear solidly dusky and bordered by yellowish moustachial stripe. Race *crossensis* male lacks metallic colours on throat, female like that of nominate; *stangerii* male has emerald-green metallic plumage not so golden-green as nominate and iridescent purple band on hindcrown narrower, female is more whitish below than nominate, with chin and throat densely barred black-brown. **VOICE.** Male song, from vantage point such as dead tree, protracted (up to 4 minutes long) and complex, initiated by rapid burst of “chip” notes (6–7 per second), followed by melodious twittering, a 4-second burst of very fast “chi” notes (11–12 per second), more twitters, bursts of “chip, chip, chip”, a trill gradually declining in volume, yet more twitters, then repetitions of 20 or more “chip” notes sometimes speeding up, the later ones preceded by 1–9 “choueee” notes. Call “chip”, typical of family.

Habitat. Forest, clearings within or at edge of forest, plantations, farms, villages, thick bush and gardens; montane grassland and heaths, to 1500 m.

Food and Feeding. Insects, small spiders (Araneae), pollen, small fruits and nectar. Feeds at *Carica papaya*, *Dalbergia*, *Erythrina abyssinica*, *Leonotis nepetifolia*, *Musa*, *Spathodea campanulata* and mistletoes (Loranthaceae). Forages 5–30 m up in trees, sometimes feeding upside-down in manner of tit (Paridae) or hovering in front of flowers. Also hawks for insects, by sallies 2–3 m from perch.

Breeding. Laying recorded in Apr, Jul–Aug and Oct in Cameroon, Mar and Nov in DR Congo, Sept–Oct in Sudan, and May–Aug and Oct–Dec in E Africa. Nest an oval pouch usually with “beard”, porch overhanging side entrance, composed of *Usnea* and other lichens, cobwebs, leaves, moss roots, fibres from *Cyathea* tree-ferns, and silk material from milkweeds (Asclepiadaceae), lined with pappus, sometimes adorned with bark, lichens, and caterpillar faeces, attached to a

Macaranga bush or 7 m up in roadside tree. Clutch 2 eggs, glossy, brown or creamy white with numerous lavender-grey, dark brown or grey-brown stripes, these parallel to long axis of egg but denser at wider end. No other information.

Movements. Probably sedentary, but all records in Zambia in Sept–Oct.
Status and Conservation. Not globally threatened. Common in most of range; uncommon in Sudan, and rare in Nigeria, Tanzania and Zambia.

Bibliography. Amadon (1953), Bannerman (1948), Benson *et al.* (1971), Borrow & Deme (2001), Brosset & Frard (1986), Carroll (1988), Carswell *et al.* (2005), Chapin (1954), Cheke (2001), Cheke & Mann (2001), Deme & Njabo (2001), Friedmann & Williams (1971), Fry *et al.* (2000), Green (1990), Hall & Moreau (1970), Hopkins *et al.* (1999), Louette (1982), McCarthy (2006), Moore (1995), Nikolaus (1987), Prigogine (1971), Rand *et al.* (1959), Serle (1957, 1963), Zimmerman *et al.* (1996).

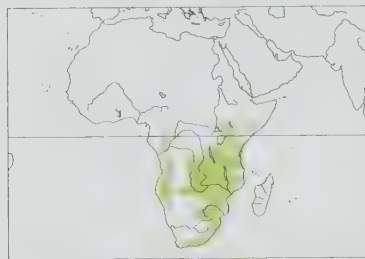

39. Amethyst Sunbird
Chalcomitra amethystina

French: Souimanga améthyste **German:** Amethystglanzköpfchen **Spanish:** Suimanga Amatista
Other common names: Black/Amethyst-throated Sunbird

Taxonomy. *Certhia amethystina* Shaw, 1811, Cape of Good Hope, South Africa. Genus previously merged with *Nectarinia*. Forms a group with *C. fuliginosa* and *C. rubescens*; sometimes thought to form a superspecies with those, despite considerable geographical overlap, but all appear to hybridize occasionally in areas where they meet. Other proposed races are *adjuncta* from E Swaziland (described from Stegi, in Lebombo Mts), which is synonymized with nominate, and *doggetti* (Ravine, in W Kenya) and *kalkkreuthi* (Mombasa, in SE Kenya), both merged with *kirkii*. Three subspecies recognized.

Subspecies and Distribution.
C. a. deminuta Cabanis, 1880 – SE Gabon, S PR Congo, W & SE DR Congo, Angola, Namibia, N & W Zambia and N Botswana.
C. a. kirkii (Shelley, 1876) – SE Sudan, SE Ethiopia (sight records), Somalia (Jubba Valley), NE Uganda, Kenya, Tanzania, Burundi, E & S Zambia, Malawi, Mozambique (S to Coguna) and Zimbabwe.

C. a. amethystina (Shaw, 1811) – E Botswana, S Mozambique (S of R Limpopo), Swaziland and E & S South Africa (Limpopo, Mpumalanga and KwaZulu-Natal S to S coastal Western Cape).

Descriptive notes. 13–15 cm; male 9.2–18.5 g, female 8.3–16.9 g. Male nominate race has iridescent green patch on forehead (sometimes appears silvery light green or gold), pinkish-violet on chin and throat, and coppery-violet on carpal; rest of plumage blackish-brown except for purplish-violet upperpart-coverts and dull black upperwing, primary and greater wing-coverts and tail; some have rudimentary yellow pectoral tufts; iris dark brown; bill and legs black. Female is olive-tinged grey-brown above, slight white supercilium, upperpart-coverts dark brown, tail blackish-brown with greyish-white tips, remiges and greater wing-coverts

dark greyish-brown, primaries and secondaries edged buff, paler on primaries, and lesser and median wing-coverts olive-grey; white moustachial stripe, pale grey-brown with heavy mottling below (except on belly), throat often so densely mottled as to appear black (pale moustache then especially obvious), underwing-coverts and axillaries brownish. Juvenile is similar to female but with throat blacker, and underparts more spotted and yellowish, looking barred (not streaked); immature male with iridescent rosy-purple patch on throat. Race *deminuta* male has shorter bill (24–28 mm) than nominate (25–32 mm), but upperpart-coverts also purplish-violet, female has throat paler, less dusky-looking (feathers lack blackish bases), underparts with variable amounts of yellow and plainer than in nominate, some with hardly any streaking; *kirkii* is similar to previous (smaller than nominate), but male upperpart-coverts blackish-brown or dull black, lacking metallic purplish-violet. A morph with red instead of violet on throat has been described from South Africa, and a xanthochromic individual with butter-yellow underparts from throat to undertail-coverts from Zimbabwe. **VOICE.** Complex song consists of ascending and descending rapid twittering, including sequences of “chip-chip-chip-choo” or “der-chip-cher-chu”; female also warbles and pair-members perform duets. Common call note a single “chip” or “tschick”, other calls include “chup” (but not the “choop” of *C. senegalensis*), also “zit-zit” and “zeebe-zeebu”, “tzwit-tzwit-zit” and similar, also both “chip” and “chop, chip-chop, cher-chip” or “cher-chop” or “chip-chip” or “ptcher-chiitzzz” ending with wheeze; “chee, chee, chee, chee” or “ssweek-ssweek-ssweek” during courtship chases; alarm calls include “t.t.t.t.t.t.t.” or “jit-jit-jit-jit...” or “choy, tit-choy, tit-choy”. Makes sounds also by clicking mandibles.

Habitat. Savanna woodlands, forest edge, gardens and hillsides with many flowering aloes (*Aloe*) and proteas (*Protea*).

Food and Feeding. Insects, including emergent termites (Isoptera); also spiders (Araneae), and nectar. A multitude of known foodplants, including species of genera *Acacia*, *Aloe*, *Abutilon*, *Baikiaea*, *Bauhinia*, *Burchellia*, *Bombax*, *Caesalpinia*, *Cassia*, *Combretum*, *Disa*, *Diospyros*, *Erythrina*, *Euclea*, *Euphorbia*, *Grevillea*, *Hibiscus*, *Kniphofia*, *Leonotis*, *Protea*, *Prunus*, *Salvia*, *Strelitzia*, *Syzygium* and *Tecoma*, and mistletoes (Loranthaceae). Hawks insects in manner of a flycatcher (Muscicapidae); also hovers in front of flowers. Gleans leaves for aphids (Aphidoidea) and takes spiders from webs. Also probes fallen fruit, and drinks oozing coconut sap.

Breeding. Laying recorded in May, Oct and Dec in Angola, Feb and Sept–Nov in DR Congo, Aug in Somalia, throughout year in E Africa (Sept–Mar and Jun–Jul in Tanzania), Sept–Feb and Apr in Malawi, Aug–Mar in Zambia, Jul–Apr in Zimbabwe, Oct, Nov, Jan and Mar in Botswana, Jan in Mozambique, and all months in South Africa; often double-brooded. Courting male chases female, continuously harasses her, and courtship dance involves hopping, drooping each wing in turn, then both simultaneously, and then fluttering each one; female hangs head down and remains motionless; cloaca-pecking recorded. Nest built by female alone, pear-shaped and sometimes “bearded”, side entrance with marked porch, constructed from fine grass, fibres, wool, hair, bark and cobwebs, adorned externally with leaves, bark, bits of wood and lichen, lined with white plant material, feathers or flower petals, suspended 2–6 m above ground from tree, clothes line, electric flex or bare wire. Clutch 1–4 eggs, usually 2, whitish to greenish or light grey, densely covered with spots, mottles, streaks and lines of dark brown, olive-brown or grey, usually denser at wider end; incubation by female alone, period 13–18 days; chicks fed by both sexes, nestling period up to 17 days; both parents feed newly fledged young. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*), African Emerald Cuckoo (*Chrysococcyx cupreus*) and Eastern Green-backed Honeyguide (*Prodotiscus zambesiae*).

Movements. Primarily resident. Partial migrant locally: influx from W in Zimbabwe in May–Aug, and visible migration to E in Botswana, where scarcer Jun–Sept. Ringing recoveries of up to 120 km in S Africa. Influxes in Tanzania (Iringa and Songea) in Apr–Oct.

Status and Conservation. Not globally threatened. Has only very small and limited ranges in Somalia, Sudan and Uganda. Common in most of rest of range. Status uncertain in SE Ethiopia; only three sight records, all in need of corroboration. Occurs in several protected areas, e.g. Arusha and Mikumi National Parks, in Tanzania, and Dzalanyama Reserve and Lilongwe Nature Sanctuary, in Malawi.

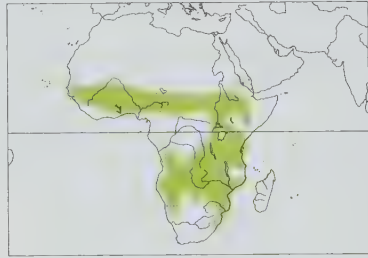

Bibliography. Baker & Baker (2007), Barnicoat (1984), Borello (1992), Borrow & Deme (2001), Brieschke (1990), Capanna & Geralico (1982), Chapin (1954), Cheke & Mann (2001), Clancey (1975), Cowles (1936), Craig & Simon (1991), Fry *et al.* (2000), Hall & Moreau (1970), Hammer (1997, 2002), Herremans (1992), Hockey *et al.* (2005), Johnson & Brown (2004), Keast (1968d), Louette (1989), Lynes (1938), McCarthy (2006), Oatley (1997), Oatley & Best (1997), Oxlee (1988), Prinzing & Jackel (1986), Prinzing *et al.* (1989), Rand *et al.* (1959), Selater & Moreau (1933), Serle (1943a), Skead (1953, 1967), de Swardt & Schoeman (1997), Tree (1991, 1997j), Tyler, D. (1992), Zimmerman *et al.* (1996).

40. Scarlet-chested Sunbird
Chalcomitra senegalensis

French: Souimanga à poitrine rouge **German:** Rotbrust-Glanzköpfchen **Spanish:** Suimanga Pechiescarlata
Other common names: Scarlet-breasted/Scarlet-throated Sunbird

Taxonomy. *Certhia senegalensis* Linnaeus, 1766, Senegal. Genus previously merged with *Nectarinia*. May form a superspecies with *C. hunteri*; sometimes regarded as conspecific, but the two are ecologically segregated in area of marginal overlap in E Kenya. Several additional races proposed: *adamauae* (described from Adamaoua, in NC Cameroon), considered inseparable from *acic*; *saturator* (from Malanje, in Angola) and *inaestimator* (Dar es Salaam, in E Tanzania), both synonymized with *gutturialis*; and *aequatorialis* (Bukoba, in NW Tanzania) and *erythrinae* (Trans Nzoia District, in Kenya), both merged with *lamperti*. Five subspecies recognized.

Subspecies and Distribution.
C. s. senegalensis (Linnaeus, 1766) – S Mauritania and Senegal E to Nigeria.
C. s. acic (Hartmann, 1866) – N Cameroon, S Chad, W & SW Sudan, N Central African Republic, NE DR Congo and NE Uganda.
C. s. proteus (Rüppell, 1840) – SE Sudan (Boma Hills), Ethiopia, Eritrea and N Kenya.
C. s. lamperti (Reichenow, 1897) – S Sudan (E of White Nile: Imatong Mts, Leboni Forest), E DR Congo (L Albert S to N L Tanganyika), W, C & S Uganda and C Kenya S to W Tanzania.
C. s. gutturalis (Linnaeus, 1766) – Angola and S DR Congo E to SE Kenya, Pemba I and Zanzibar, S to C Namibia, N Botswana, Mozambique, and E South Africa (Limpopo Province S to KwaZulu-Natal and N Eastern Cape).

Descriptive notes. 13–15 cm; male 7.5–17.2 g, female 6.8–15.3 g. Male nominate race has metallic emerald crown with golden sheen, otherwise very dark brown above, upperpart-coverts brown with darker brown edges; newly moulted wing and tail feathers brown (fading to cinnamon-brown when older), lesser wing-coverts and scapulars blackish-brown; chin and upper throat and malar stripe metallic green, lower throat and breast bright vermillion with narrow metallic purplish-blue or bluish-green subterminal bars on each feather; rest of underparts very dark brown; iris dark brown; bill and legs greenish-black. Female is brown

above, including upperwing and wing-coverts, white edges on primary coverts and alula and on inner lesser coverts, tail brown, darker near tip, narrowly edged white, chin and throat narrowly barred light brown on dark brown ground (looking mottled), underparts pale yellow, strongly marked with dark brown (particularly on belly), undertail-coverts dark brown with yellowish-white tips. Immature male is like female on upperparts but, below, has metallic green on chin and upper neck, blackish throat and breast, yellow belly with heavy dark mottling and barring, also red on chest and some metallic plumage colours on head. Race *acic* male has red on chest lighter, lacking gloss and with less marked metallic blue barring, and green malar stripe smaller than that of nominate; *lamperti* resembles previous, but male has heavier and longer bill (28–31 mm; *acic* 22–26 mm), female underparts paler and less heavily marked; *proteus* male has small metallic violet spot on lesser wing-coverts, black chin and upper throat bordered with green moustachial stripe, upperwing paler than that of previous two races and contrasting more with black, female lacks white edges on primary coverts and alula, and has belly paler yellow; *gutturialis* male has metallic violet spot on lesser wing-coverts (absent in other races except preceding one) and female has yellower underparts, male takes two years to gain breeding plumage and some have eclipse plumage (combination of fresh female-like plumage and old breeding plumage). **VOICE.** Song involves variations (four or five syllables) of “chip-choop-chip-choo-choo” lasting 1–2 seconds, before repeats of “chip” at rate of five times per second and faster series of “chi” or twittering, which may be whistling “weetodu-weetodu” among a series of “chip” (race *gutturialis*) or “weet” or “weetu” (nominate). Singing sessions, sometimes including immature males, can last for more than an hour. Common call “choop” or “tjoyp”; also variations involving “chip-chip” and “tsee-tsee”.

Habitat. Wooded savannas, e.g. *Acacia* (*Acacia*) savanna, miombo, mopane. Also semi-arid thornscrub, gallery forest in dry savanna, coastal scrub, rocky outcrops, parks, gardens, plantations, farmland, dry baobab (*Adansonia*) woodland and among proteas (*Protea*).

Food and Feeding. Nectar, insects, and spiders (Araneae). Nestling diet small insects. Many known foodplants, including species of genera *Acacia*, *Albizia*, *Aloe*, *Baikiaea*, *Bauhinia*, *Bombax*, *Bougainvillea*, *Caesalpinia*, *Callistemon*, *Canna*, *Carica*, *Cassia*, *Celaena*, *Citrus*, *Combretum*, *Crotalaria*, *Dalbergia*, *Delonix*, *Erianthemum*, *Erythrina*, *Euphorbia*, *Gmelina*, *Grevillea*, *Halleria*, *Hibiscus*, *Kigelia*, *Kniphofia*, *Leonotis*, *Manihot*, *Musa*, *Parkia*, *Protea*, *Prunus*, *Spathodea*, *Symphonia*, *Syzygium*, *Tapinanthus*, *Tecoma*, *Thevetia* and *Vitex*. Forages singly and in pairs or, often, in groups. Male defends feeding territories against other males and conspecific females; also deters other sunbirds, such as *Anthreptes longuemare*. Sometimes hovers in front of flowers, grasses or leaves; takes insects on the wing in manner of a flycatcher (Muscicapidae). Also hovers at spider webs and seizes prey trapped in them.

Breeding. Laying recorded in Jun and Dec in Gambia, May and Jul–Sept in Ghana, Jul in Niger, Feb–Oct in Nigeria, May and Jul in Cameroon, Apr and Jul–Sept in Sudan, Jul–Aug in Ethiopia and Eritrea, Apr in Angola, Mar, May, Jun, Aug–Oct and Dec in DR Congo, Mar–Jul, Aug and Oct

in Uganda, Jan–Feb and Aug in Kenya, all months (peaks in Feb–Mar and Nov–Dec) in Tanzania, Jan–Mar and Jun–Oct on Zanzibar, Jul–Mar in Zambia, Feb–May and Jul–Dec in Malawi, Nov–Apr in Namibia, Aug–Dec in Botswana, Jul–Apr and Jun in Zimbabwe, Sept–Mar in Mozambique, and Aug–Jan in South Africa; double-brooded or triple-brooded in some areas. Territorial. Male makes side-to-side movement of body in courtship displays to female. Nest built by female, sometimes in just 3–6 days, a bulky dome, side entrance with porch of dead grass heads overhanging for 4 cm, made of spider web, bark, leaves and grass, adorned with leaf skeletons, feathers, wool, string, paper and insect faeces, lined with plant down, hair and feathers, short “beard” of grass, leaves and bark hanging down to 5 cm below base, suspended 1.5–15 m above ground in tree, from creepers, but also recorded near house (e.g. on electric-light flex); sometimes protected by close association with nests of polistine wasps (*Ropalidia*); same nest sometimes used for up to three broods, or new one built for each attempt. Clutch 1–3 eggs, variable, with background of dirty white or pinkish-white to purple, blue-green or light green, with brown, green or grey streaks, mottles, lines, spots and blotches, denser at broad end; incubation by female, period c. 2 weeks; chicks fed by both parents, nestling period up to 23 days; fledglings roost in nest for at least 4 nights after fledging, but can take nectar independently 9 days after abandoning nest. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*), African Emerald Cuckoo (*Chrysococcyx cupreus*) and Greater Honeyguide (*Indicator indicator*); pair seen to chase away Brown-backed Honeyguide (*Prodotiscus regulus*), but nest parasitism by this species unconfirmed.

Movements. Sedentary, but in many populations nomadic and migratory movements occur. Dry-season influxes reported in Zimbabwe (Mar–Jul) and Kenya (Feb–Apr and Sept–Nov). Wet-season visitor to Namibia in Nov–Apr, and in Tanzania ascends to higher altitudes to breed. In W Africa, probably moves N with rains; in Mauritania most records in Jun–Nov wet season. For race *gutturialis*, ringing recoveries of up to 153 km (males) and up to 360 km (females).

Status and Conservation. Not globally threatened. Abundant and widespread in savanna woodland throughout most of range; rare in Mauritania and on Pemba I. Occurs in many protected areas, e.g. Abuko Nature Reserve, in Gambia, Comoé National Park, in Ivory Coast, Bénoué National Park, in Cameroon, Murchison Falls National Park, in Uganda, Arusha and Mikumi National Parks, in Tanzania, Lilongwe Nature Sanctuary, in Malawi, Etosha National Park, in Namibia, and Mkuze Game Reserve, in South Africa.

Bibliography. Anon. 41. Hunter’s Sunbird

Chalcomitra hunteri

French: Souimanga de Hunter **German:** Purpurbürzel-Glanzköpfchen **Spanish:** Suimanga de Hunter

Taxonomy. *Cinnyris hunteri* Shelley, 1889, Useri River, Kenya–Tanzania border. Genus previously merged with *Nectarinia*. May form a superspecies with *C. senegalensis*; sometimes regarded as conspecific, but the two are ecologically segregated in area of marginal overlap in E Kenya. Two subspecies recognized.

Subspecies and Distribution.

C. h. siccata (Clancey, 1986) – extreme SE Sudan, SSW Ethiopia (near Mega), NW Kenya (including NW shore of L Turkana), and plateau regions of Somalia.

C. h. hunteri (Shelley, 1889) – S & EC Ethiopia, Kenya (except NW) and extreme NE Tanzania.

tail darker but outer tail feathers paler than rest, with outer two pairs tipped white, primaries edged white, tertials and greater wing-coverts edged buff, median and lesser wing-coverts tipped greyish-brown; ear-coverts and cheeks greyish-brown, narrow moustachial stripe very pale brown; chin and throat darker greyish-brown with pale brown bars, underparts pale brownish-white, heavily mottled greyish-brown on breast and flanks; axillaries buff, underwing-coverts greyish-brown with paler tips; bare parts as male. Juvenile is like female, but more heavily barred and mottled on underparts, and lacks moustachial stripe; immature male similar, but moustachial stripe green, chin and throat black, and has scarlet gorget with blue bars. Race *siccata* differs from nominate in black of adult male being more brownish-tinged (not jet-black), breast more orange than scarlet and with buffish subterminal barring on lower part. **VOICE.** Complex song of rising and falling notes, a whistle and a trill, preceding “chip, chip-choo” and “chip” repeated every 1–2 seconds.

Descriptive notes. 13–14 cm; 10–14 g. Male nominate race has forehead and crown iridescent green, face, neck and upperparts black, uppertail-coverts and base of rump iridescent purple; upperwing and tail blackish-brown, metallic purple patch on lesser wing-coverts; black chin and upper throat bordered by green moustachial stripes; scarlet lower throat and breast, feathers with faint iridescent blue and green bands near tips reflecting yellow or violet (most noticeable on lower throat and side of breast), rest of underparts and underwing black; iris brown; bill and legs black. Female is greyish-brown above, uppertail-coverts and

Call “chip” or “tew” repeated up to four times in quick succession, and “choo-choo-choo” or “tchi-tchi-tchi-tch...”.

Habitat. Scrub, open woodland and semi-arid grasslands, to 1500 m.

Food and Feeding. Insects, also fruit pulp and nectar. Takes fruit pulp from *Commiphora* species; feeds at flowers of acacias (*Acacia*), *Acrocarpus fraxinifolius*, aloes (*Aloe*), *Delonix elata*, *Erythrina*, *Kigelia africana*. Perches on or hovers in front of flowers to take nectar. Leaf-gleans for insects, and catches latter also in mid-air.

Breeding. Egg-laying recorded in May and Jul in Somalia, Feb, Jun, Oct and Dec in Kenya and Dec in Tanzania. Nest built by female, ellipsoid and domed, made from grass, leaves, bark, feathers, rootlets and paper held together by spider webs, adorned with lichen, thickly lined with feathers, including those of Vulturine Guineafowl (*Acryllium vulturinum*), with 20-cm “beard”, female continues to line nest after beginning to incubate; generally suspended up to 2 m up in tree, sometimes in or on house or house fitting. Clutch 1–2 eggs, white, pale green-grey or olive-grey with numerous brown streaks and other markings and dark grey speckles, concentrated at wider end; incubation by female, no information on duration of incubation and nestling periods.

Movements. No data.

Status and Conservation. Not globally threatened. Fairly common and widespread throughout Somalia, except in NE and extreme W; fairly common in dry habitats, except grassland, in Kenya. Uncommon in Ethiopia and S Sudan. Reports of presence in Uganda require corroboration.

Bibliography. Archer & Godman (1961), Baker & Baker (2007), Carswell *et al.* (2005), Cheke & Mann (2001), Clancey (1986), Friedmann (1937), Fry *et al.* (2000), Hall & Moreau (1970), Lack (1976, 1985), Lewis & Pomeroy (1989), McCarthy (2006), Nikolaus (1987), Serle (1943a), Zimmerman *et al.* (1996).

42. Socotra Sunbird

Chalcomitra balfouri

French: Souimanga de Socotra **German:** Sokotranektarvogel **Spanish:** Suimanga de Socotora
Other common names: Socotra Island Sunbird

Taxonomy. *Cinnyris balfouri* P. L. Sclater and Hartlaub, 1881, Socotra.

Genus previously merged with *Nectarinia*. Relationships uncertain. Possibly closest to *C. hunteri*, *C. amethystina* or *C. rubescens*, but differs from all congeners in lacking pronounced sexual dichromatism (both sexes looking like females of other members of genus); has been thought perhaps to be closest to *Cinnyris dussumieri*, another island species but currently placed in a different genus. Further research required. Monotypic.

Distribution. Socotra.

Descriptive notes. Male 12.5–14 cm, female 11.5–12 cm; unsexed 8–15 g. Male is dull brown above, with pale streaking on crown, and fewer similar streaks on nape and mantle; sooty-black lores and area around eye, narrow buffy grey supercilium extending back beyond ear-coverts; tail blackish with slight bluish gloss, white outer webs of outer rectrices, and white tips on all rectrices (diminishing in size from outer to inner); primaries dark brown with greyish-white and olive edging (forming pale panel), upperwing-coverts dull brown with greyish edging; narrow dull black moustachial stripe, white submoustachial stripe broadening towards cheek, black malar stripe; chin and throat dark greyish-brown with darker mottling; feathers of breast dark brown, broadly tipped grey (giving scaled effect), belly pale grey, slightly scaled on upper belly and at side, flanks become pale greyish-brown towards rear, vent to undertail-coverts white; pectoral tufts bright yellow, underwing-coverts pale greyish-white; iris red or reddish-brown; bill and legs blackish. Female is very similar to male but smaller, has barred submoustachial stripe, less clearly patterned chin to lower breast, and lacks pectoral tufts. Juvenile differs from adult in having brown iris, pale yellowish lower mandible, and dark grey feet with yellowish soles. **VOICE.** Song loud and varied, a series of short or long bursts of quick jangling notes; also mimics other species, including Socotra Warbler (*Incana incana*). Shrill hoarse alarm calls, squeaky, strident “zii”; alarm or aggressive call harsh and grating “tcheep-up” or “tchee”.

Habitat. All vegetated areas, and more numerous where vegetation is more substantial; sea-level to 1370 m.

Food and Feeding. Insects, including small cicadas (Cicadidae), also spiders (Araneae); also small fruits (e.g. of *Euphorbia*), seeds and presumably nectar. Forages singly and in pairs. Very active; catches insects in flight or on the ground. Seen to probe flowers, including those of *Calotropis procera*, *Croton* species and *Trichocalyx obovatus*.

Breeding. Laying probably in Jan–May; nestlings found in Mar and May, fledglings in Feb, and juveniles early Feb to late Mar. Nest dome-shaped, with large oval entrance, made of loosely woven fine grasses and cobwebs, lined with white plant wool and possibly goat hair, concealed among branches 2.5 m above ground in *Euphorbia arbuscula* tree or suspended in thick bush and creepers. Clutch 1–3 eggs. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Restricted-range species: present in Socotra EBA. Common. Total population estimated at approximately 11,000 pairs; densities 6–12 birds/km². Overgrazing could reduce numbers of this island-restricted species.

Bibliography. Cheke & Mann (2001), Forbes (1903), Fry *et al.* (2000), Hall & Moreau (1970), Martins *et al.* (1993), Ogilvie-Grant & Forbes (1903), Porter & Martins (1993), Ripley & Bond (1966), Showler & Davidson (1996).

PLATE 12

Genus *LEPTOCOMA* Cabanis, 1851

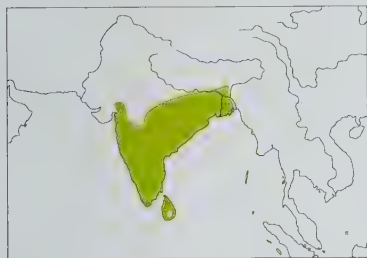

43. Purple-rumped Sunbird

Leptocoma zeylonica

French: Souimanga à croupion pourpre **German:** Ceylonnektarvogel **Spanish:** Suimanga Cingalés
Other common names: Indian Purple-rumped Sunbird

Taxonomy. *Certhia zeylonica* Linnaeus, 1766, Sri Lanka. Genus often subsumed in *Nectarinia*. Genus names *Leptocoma* and *Chalcostetha* described simultaneously, on consecutive pages of same publication; former has been selected by First Reviser as having precedence (see page 48). Present species probably closest to *L. minima*. Geographical variation minimal. Other proposed races, both from peninsular India, are *whistleri* (described from Muddur, in Karnataka) and *sola* (from Pondicherry, in Tamil Nadu), both considered unsustainable and included in *flaviventris*. Two subspecies recognized.

Subspecies and Distribution.
L. z. flaviventris (Hermann, 1804) – peninsular India (E to W Meghalaya) and Bangladesh.
L. z. zeylonica (Linnaeus, 1766) – Sri Lanka.

Descriptive notes. 10 cm; male 7–11 g, female 7–9 g. Male nominate race has metallic green crown and shoulder patch, deep chestnut-maroon side of head, nape and back, and metallic purple rump and uppertail-coverts; upwings and tail black, remiges edged brown; metallic purple throat bordered below by deep chestnut-maroon; breast and centre of belly lemon-yellow, flanks greyish-white, vent and undertail-coverts yellowish-white, large pale grey terminal spots on outer rectrices; iris orange-brown to reddish-brown; bill brownish-black; legs brownish or black. Female is brown with olive tinge above, narrow whitish supercilium,

blackish eyestripe, rufous edging on remiges, large pale grey terminal spots on outer rectrices; throat and flanks greyish-white, throat sometimes with buffy or slightly yellowish wash, breast and centre of belly lemon-yellow. Juvenile is as female, but throat and whole underparts very pale lemon-yellow. Race *flaviventris* is larger than nominate, and male is more reddish-purple, less bluish-purple, on throat. **VOICE.** Song a sharp twittering “tityou, tityou, tityou, tr-r-r-tit, tityou...”, also a feeble “sisiswee, sisiswee...”; described also as a high, thin, even-tempo series of upstrokes, pitch descending after every few notes, e.g. “sit-sit, tset-tset-tset-tset, tsut-tsut-tsut”. Call an almost constant “sweet-sweet, sweet-sweet-sweet”; short high-pitched metallic “tzip”.

Habitat. Various types of forest and jungle, including secondary forest, at forest edge, in farmland, dry cultivation, hedges, isolated trees, and gardens. Lowlands to 1050 m, occasionally 2100 m, in India; to 1400 m in Sri Lanka.

Food and Feeding. Insects, including caterpillars, also spiders (Araneae); also nectar and grapes, and fruits of mistletoes (Loranthaceae) probably eaten. Takes nectar from flowers having large corollas. Forages singly and in pairs. Very active.

Breeding. Laying recorded in all months in India, peaks Mar–May in West Bengal, Dec–Apr and Jul–Sept (after monsoon) in S, and Jun–Sept (during rains) in W (at Pune); in all months also in Sri Lanka, with peak Feb–Jun and second brood Aug–Nov. Unusually in family, male helps female in nest construction, one nest completed in 6 days; a pear-shaped or oval purse, usually with porch, constructed from grass, fibres and oddments, decorated externally with lichen, bark, moss, caterpillar frass, broken leaves and variety of other rubbish, lined with soft vegetable down, and suspended from tip of tree branch 2–15 m above ground, sometimes outside or inside dwelling, attached to creepers, trellis or wire, and even to pendent electric light bulb; new nest constructed for each clutch. Clutch 2 or 3 eggs, plain greyish-white, or grey with greenish or buff tinge, with greyish-brown flecks and speckles, particularly at broader end; incubation by female, guarded at nest by male, period 15–16 days; chicks fed by both sexes, both also remove faecal sacs, nestling period 11–14 days. Nests parasitized by Plaintive Cuckoo (*Cacomantis merulinus*).

Movements. Resident. In Sri Lanka ascends to highest altitudes during NE monsoon.
Status and Conservation. Not globally threatened. Common in India, Bangladesh and Sri Lanka. Possible occurrence in W Myanmar requires corroboration. An important propagator of mistletoes, but considered a pest in parts of India because of its fondness for grapes. Occurs in several protected areas, e.g. Rajiv Gandhi (Nagarhole) National Park, in SW India (Karnataka).

Bibliography. Ali (1969), Ali & Ripley (1974), Bharucha (1982), Chattopadhyay (1980), Cheke & Mann (2001), Choudhury (1990), Ganguly (1986), Kumar *et al.* (1984), Lamba (1978), Leandri (1950), Oates (1890a, 1890b), Parasharya & Vyas (2002), Raju (1998, 2001), Raju & Reddi (1989), Rasmussen & Anderton (2005b), Robson (2000b), Wait (1931), Wesley (2004).

44. Crimson-backed Sunbird

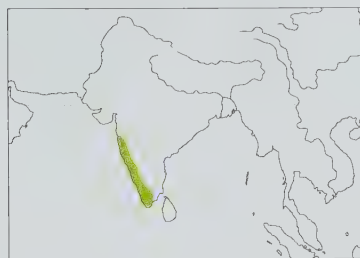

Leptocoma minima

French: Souimanga menu **German:** Däumlingsnektarvogel **Spanish:** Suimanga Mínimo
Other common names: Small Sunbird

Taxonomy. *Cinnyris minima* Sykes, 1832, Western Ghats, Deccan, west India. Genus often subsumed in *Nectarinia*. Genus names *Leptocoma* and *Chalcostetha* described simultaneously, on consecutive pages of same publication; former has been selected by First Reviser as having precedence (see page 48). Present species probably closest to *L. zeylonica*. Monotypic.

Distribution. Western Ghats (from N of Mumbai, S to hills of S Kerala), in W India.

Descriptive notes. 8 cm; male 4–6 g, female 4–5 g. Very small. Male breeding has crown iridescent green, side of face blackish, upwings and tail blackish-brown with lilac gloss, back and shoulder deep red, and rump metallic purple or lilac; purple throat, crimson upper breast bordered with blackish band below, dull yellow belly, bright lemon pectoral tufts, greyish-white flanks; iris dark brown; bill and legs blackish. Male in non-breeding plumage (Apr/May–Aug) is similar to

female, but brighter olive on head, with back and shoulders metallic red, rump and uppertail-coverts metallic purple; lesser upperwing-coverts metallic red, forming with adjacent part of back a broad band. Female is olive above, with lower rump and uppertail-coverts deep maroon-crimson, remiges edged brown and olive, dull yellow below; iris dark brown, bill and legs blackish but paler than male, particularly at base of lower mandible. Juvenile resembles female but greyer, with duller red rump, more yellow below. **VOICE.** Squeaky song “see-see-whi-see-see-siwee...” lasting 5–10 seconds, frequently repeated; also described

as high, thin, tinkly, irregular warble, “tseet-tsut-tseet”, notes in pairs or triplets, alternating in pitch. Call a continuous metallic “chik” during foraging; also various high-pitched, metallic ticking and chattering calls.

Habitat. Evergreen forest, sholas, plantation shade trees, secondary growth and gardens; 300–2100 m, chiefly in foothills.

Food and Feeding. Insects, spiders (Araneae) and nectar. Forages singly, in pairs or in small groups. Active and acrobatic; clings upside-down to plants, also hovers. Defends flowering trees against conspecifics, also against flowerpeckers (Dicaeidae).

Breeding. Laying recorded in Feb–Mar, May and Dec in Mumbai area, Sept–Apr in Kerala but May–Oct in Nilgiris. Nest a neat, rounded, hanging pouch of fibres, moss and cobwebs, suspended from tip of twig within 2 m of ground in bush or sapling, commonly on *Strobilanthes* plant, on edge of path or clearing. Clutch 2 eggs; white with dense ring of reddish spots, and speckled reddish. No other information.

Movements. Local movement; absent from most of Nilgiris Oct–Mar.

Status and Conservation. Not globally threatened. Restricted-range species: present in Western Ghats EBA. Locally common. Claimed occurrence in Sri Lanka (and reports of breeding in Mar–Apr) in early 20th century believed to be erroneous.

Bibliography. Ali & Ripley (1974), Cheke & Mann (2001), Davidar (1985b), Grimmett *et al.* (1998), Henry (1971), Khan (1977), Oates (1890a, 1890b), Rasmussen & Anderton (2005b), Ripley (1961a), Santharam (1996b), Wait (1931).

45. Purple-throated Sunbird

Leptocoma sperata

French: Souimanga de Hasselt **German:** Purpurkehl-Nektarvogel **Spanish:** Suimanga Gorjipúrpura
Other common names: (van) Hasselt’s Sunbird (*sperata*); Philippine/Luzon/Henke’s Sunbird (*henkei*); Mindanao Sunbird (*juliae*)

Taxonomy. *Certhia sperata* Linnaeus, 1766, Manila, Luzon, Philippines. Genus often subsumed in *Nectarinia*. Genus names *Leptocoma* and *Chalcostetha* described simultaneously, on consecutive pages of same publication; former has been selected by First Reviser as having precedence (see page 48); type of genus *Leptocoma* is *hasseltii* (= *brasiliانا*). Present species possibly forms a superspecies with *L. sericea*. Geographical plumage variation considerable; races form two groups, “nominate group” (containing Philippine races) and “*brasiliانا* group” (containing other races), and has been suggested that these may be better treated as two distinct species. Races *mecynorhyncha* and *oenopa* perhaps not tenable, and could perhaps be merged with *brasiliانا*. Nominate race intergrades and hybridizes with *henkei* (hybrids described as race *theresae*) and with *juliae* (hybrids described as race *davaoensis*); an apparently stable hybrid population exists on Sibuyan (NC Philippines). Other proposed races in Philippines are *manueli* (from Karlagan, in Polillo Is), synonymized with nominate; *minima* (Mati Municipality, in Davao Province of Mindanao) synonymized with *trochilus*; and *whiteheadi* (N Luzon), subsumed in *henkei*. Elsewhere, proposed races *phayrei* (Myanmar), *oenopa* (Nias I, off W Sumatra) and *hypolampis* (South Pagai I, off W Sumatra) all included in *brasiliانا*; also, *hasseltii* (Java) is a synonym of *brasiliانا*. Birds of this species recorded recently in N Vietnam probably belong to race *emmae*. Described form *minduquensis* is based on misidentification of female of *Aethopyga siparaja* (of race *magnifica*). Nine subspecies recognized.

Subspecies and Distribution.

L. s. brasiliانا (J. F. Gmelin, 1788) – NE India (Assam, Tripura, Manipur), Bangladesh hills and W & SW Myanmar S to S Thailand, Peninsular Malaysia and Sumatra (and islands off W coast except Simeulue), and W Java and Borneo.

L. s. emmae Delacour & Jabouille, 1928 – Cambodia, S Laos and S Vietnam (probably also this race in Tonkin).

L. s. mecnorhyncha (Oberholser, 1912) – Simeulue I (off W Sumatra).

L. s. eumecis (Oberholser, 1917) – Anamba Is, off E Peninsular Malaysia.

L. s. axantha (Oberholser, 1932) – N Natuna Is.

L. s. henkei (A. B. Meyer, 1884) – Calayan, Babuyan Claro, Fuga and Camiguin Norte, and mountains of N & C Luzon, in N Philippine Is.

L. s. sperata (Linnaeus, 1766) – N Philippines (C & S Luzon, Polillo, Marinduque and Cantanduanes).

L. s. trochilus (Salomonsen, 1953) – W, C & S Philippines (Lubang, Mindoro, Busuanga, Culion, Tablas, Romblon, Sibuyan, Masbate, Ticao, Palawan, Dadagican, Ursula, Balabac, Panay, Guimaras, Biliran, Leyte, Samar, Basiao, Calicoan, Negros, Cebu, Bohol, Siquijor, Camiguin Sur, Dinagat, Nipa, Siargao, Bucas Grande, E Mindanao, Talicud, Pujada, Balut); also Maratua Is, off E Borneo.

L. s. juliae (Tweeddale, 1877) – W & C Mindanao and Sulu Archipelago (Malanipa, Malamaui, Basilan, Tonquil, Jolo, Siasi, Tawi-Tawi, Sanga Sanga, Bongao, Simunul, Sibutu), in S Philippines.

Descriptive notes. 9–10 cm; 5.2–7.5 g. Male nominate race has crown iridescent coppery green or golden-green, side of neck, mantle and scapulars maroon, lower back, rump and uppertail-coverts metallic green, tail black glossed blue; upwings black, remiges with orange-red edgings; lores, side of face to ear-coverts and malar area blackish; chin and throat iridescent purple or violet-purple, breast to upper belly scarlet to orange, belly and undertail-coverts yellowish-olive, yellowish-green or yellow (belly greyer in C Luzon); iris brown to dark brown; bill and legs black. Female is mostly olive-green, with wing edging brownish, brighter below, becoming more yellow and whitish from lower breast to vent; all except central rectrices narrowly tipped greyish. Juvenile is similar to female, but greyer below, later becoming browner above and whitish below. Races differ

mainly in plumage coloration and pattern; *henkei* male differs from nominate in having black mantle and duller wings; *irochilus* differs from nominate in having iridescent bronze-green crown, with pectoral spot, lower back, rump and undertail-coverts iridescent blue-green, tail dark purple, and lower belly to undertail-coverts dark olive to olive-grey; *juliae* male differs from nominate in having variable amounts of mauve-red gloss and green on crown, dark crimson (instead of red-brown) mantle, red or brownish-red edging on remiges, tail more purple-blue, breast bright orange-yellow with variable amounts of scarlet, belly

to vent yellow-green; *brasiliiana* male differs from nominate in having mantle black, rump and shoulder patch metallic purple-blue, breast and upper belly deep maroon-crimson, and rest of underparts sooty brown, female olive above with black tail, yellow below, brighter on belly; *emmae* male differs from previous in having more bluish (rather than greenish) gloss on back; *meenynorhyncha* has much longer bill than *brasiliiana*, male usually darker on lower underparts, female more greenish above and darker and duller below; *eumecis* is larger and has longer bill than *brasiliiana*, female is lighter above and paler and more greenish below; *axantha* is similar to last but larger, female brighter and more yellowish above, darker and more olivaceous below. **Voice.** Song "psweet, psweet, psweet, psweet, psweet, psweet...psit-it, psitit, psweet, psweet...". Calls include weak "chip chip", sharp "si-si-si", also "wheep"; double whistle, first note rising and second falling; high-pitched "tiswit...titwitwit"; flight call "chit chit chit chit"; also described for India are a piercing, thin, strongly upslurred "pswécéé", more subdued, staccato, quick, disyllabic "fut-chit", and short, high trills.

Habitat. Found in many forest types, including peat-swamp-forest, heath forest, montane forest and mangroves; also heavily disturbed forest, closed-canopy secondary forest, plantations, coconut groves, coastal scrub, and gardens. Mostly not far from coast, but up to 110 km inland in Peninsular Malaysia; generally sea-level to 200 m, but to 1220 m in Peninsular Malaysia, and 1000 m in N Borneo (Sabah).

Food and Feeding. Insects, including caterpillars and aphids (Aphidoidea); also nectar, fruit and seeds. Forages singly, in pairs or in small groups; sometimes in flocks of up to c. 30 individuals. Usually forages high, and hovers to take insects or water from leaves and nectar from flowers; also hangs from flowers to take nectar, and removes insects from spider webs.

Breeding. Laying recorded in Feb–May in Bangladesh, Apr–May and Jul in Thailand, probably late Jan to May and Jul (nest-building seen late Feb, Apr, May, early Aug) in Malay Peninsula, and Jan and Mar–Jun in Java; fledglings early Jun in Singapore; in Borneo, laying recorded Sept and birds with active gonads Jan–Feb, Apr and Jun in N (Sabah), and juveniles in Aug in S; in Philippines, nest with eggs in Apr in N (Camiguin Norte), laying in Dec on Palawan, Jan on Negros, Feb on Siquijor and Apr on Samar, and bird with active gonads in Apr on Marinduque. Nest globular, with side entrance near top, with or without "tail", made from grass stems, epiphyte rootlets, fibres, leaves and cobwebs, lined with fibrous material, camouflaged with dry leaves, bark and small twigs, and screened by leaves, attached to branch or tip of palm frond 1.5 to 10 m above ground. Clutch 2 eggs, brown. No other information.

Movements. Some seasonal movements recorded in India and Bangladesh and in Borneo. Apparently regularly crosses water to and from Singapore.

Status and Conservation. Not globally threatened. Generally local or rare in India; common in E Bangladesh (Sylhet), mainly Oct to mid-Jan. Locally common in Thailand; but uncommon in S; common and widespread on coast of Peninsular Malaysia, but local inland; generally uncommon in Greater Sunda; common in Philippines. Reports of presence in extreme NE India (NE Arunachal Pradesh) are unsubstantiated. Occurs in several protected areas, e.g. Khao Pra Bang Wildlife Sanctuary, in Thailand, Cat Tien National Park, in Vietnam, and St Paul Subterranean River National Park and Rajah Sikatuna National Park, in Philippines; rare in Danum Valley Conservation Area, in Borneo.

Bibliography. Ali & Ripley (1974), Allen *et al.* (2006), Birand & Pawar (2004), Cheke & Mann (2001), Curio (1994), Dickinson *et al.* (1991), Edgar (1947), Gill (1969), Gilliard (1950a), Grimmer *et al.* (1998), Hellebrekers & Hoogerwerf (1967), Hill (2000), Hoogerwerf (1949), Kennedy *et al.* (2000), MacKinnon & Phillips (1993), Mann (2002), McGregor (1909), Medway & Wells (1976), Nash & Nash (1988), Oates (1890b), Ogilvie-Grant (1894), Plettler (1961), duPont (1971b), Rahor (1977), Rajathurai (1996), Rand & Rahor (1960), Rasmussen & Anderton (2005b), Reed (1971), Ripley & Rahor (1958), Robson (2000b), Salomonsen (1952, 1953b), Sheldon *et al.* (2001), Smythies & Davison (1999), Wells (2007).

46. Black Sunbird

Leptocoma sericea

French: Souimanga satiné **German:** Seidenmektarvogel **Spanish:** Suimanga Negro

Taxonomy. *Cinnyris sericeus* Lesson, 1827, near Dorey, New Guinea.

Genus often subsumed in *Nectarinia*. Genus names *Leptocoma* and *Chalcostetha* described simultaneously, on consecutive pages of same publication; former has been selected by First Reviser as having precedence (see page 48). If present genus is merged into *Nectarinia*, species name *sericea* becomes preoccupied, and must be replaced by next junior synonym, *aspasia*. Possibly forms a superspecies with *L. sperata*. Considerable geographical variation chiefly in gloss colour of males, but in *L. w-cline* in some characters apparent in C parts of range (involving races *auriceps*, *aspasioides*, *mariae* and *cochrani*). Races *corinna* and *vicina* not particularly well marked, and could perhaps be included in nominate. Other proposed races are *tonkeana* (from I: Sulawesi), included in *porphyrolaema*; *morotensis* (Morotai, off N Halmahera), merged with *auriceps*; *olympia* (Misool, in West Papuan Is.), in *cochrani*; *bergmanni* (Adi I, off S Bomberai Peninsula, in W New Guinea), included in nominate; and *chlorocephala* (Wokam, in Aru Is.), synonymized with *aspasioides*. Proposed name *johiensis* (Yapen I, in Geelvink Bay), is older than *salvadorii*, but appears to have been based on specimens of nominate *sericeus*, and may in any case have to be considered a *nomen oblitum*; material for *salvadorii* may have come not from Yapen but from nearby Mios Num; further study required. Junior synonym *theresia* was formerly used as new name for *chlorolaema*, which was erroneously believed preoccupied. Twenty-three subspecies recognized.

Subspecies and Distribution.

L. s. grayi (Wallace, 1865) – N Sulawesi, including small islands of Manado, Bangka and Lembah. *L. s. porphyrolaema* (Wallace, 1865) – Sulawesi (except N), including Togian Is, Muna, Butung and Labuan Blanda.

L. s. sangirensis (A. B. Meyer, 1874) – islands of Sangihe, Siau and Ruang (N of Sulawesi).

L. s. talautensis (A. B. Meyer & Wilesworth, 1894) – Talaut Is (NE of Sulawesi).

L. s. auriceps (G. R. Gray, 1861) – Tifore, Morotai, Halmahera, Ternate, Mare, Makian, Bacan, Obi, Damar, Muor and, Gebe; also archipelagos of Banggai and Sula (off E Sulawesi).

L. s. auricapilla (Mees, 1965) – Kayoa I (off W Halmahera).

L. s. cochrani (Stresemann & Paludan, 1932) – West Papuan Is (Waigeo, Misool).

L. s. mariae (Ripley, 1959) – Kofiau I (N of Misool).

L. s. proserpina (Wallace, 1863) – Buru I.

L. s. aspasioides (G. R. Gray, 1861) – Seram, Ambon, Nusa Laut, Watubela Is and Aru Is.

L. s. chlorolaema (Salvadori, 1874) – Kai Is.

L. s. sericea (Lesson, 1827) – New Guinea (including islands of Manam, Karkar, Adi, Gag), except SE.

L. s. maforensis (A. B. Meyer, 1874) – Numfor I (in Geelvink Bay), in NW New Guinea.

L. s. mysorensis (A. B. Meyer, 1874) – Biak I (in Geelvink Bay) and Schouten Is (off NC New Guinea).

L. s. nigriscapularis (Salvadori, 1876) – Meos Num and Rani I (in Geelvink Bay).

L. s. salvadorii (Shelley, 1877) – Yapen I (in Geelvink Bay).

L. s. veronica (Mees, 1965) – Liki I, off NW New Guinea.

L. s. cornelia (Salvadori, 1878) – Tarawai I, off CN New Guinea.

L. s. corinna (Salvadori, 1878) – N Bismarck Archipelago (except Feni Is).

L. s. eichhorni (Rothschild & E. J. O. Hartert, 1926) – Feni I, E of New Ireland.

L. s. caeruleogula (Mees, 1965) – Umbi I and New Britain.

L. s. vicina (Mayr, 1936) – SE New Guinea.

L. s. christinae (Tristram, 1889) – Trobriand Is, D'Entrecasteaux Archipelago, Marshall Bennett Group, Woodlark I and Louisiade Archipelago, off SE New Guinea.

Descriptive notes. 11–11.5 cm; mean 8 g. Male nominate race is chiefly black, with head glossy bluish-green, greenish-blue gloss on rump, uppertail-coverts and tail, and median and lesser upwringing-coverts, rump feathers sometimes with purple edging; throat and breast with reddish-purple and purplish-blue or blue gloss; iris brown; bill and legs blackish. Female is much smaller than male, lacks gloss in plumage, has head grey, paler on throat, wings and mantle olive-grey or olive-green, white tips of tail feathers, belly pale yellow. Juvenile resembles female, but is greener on crown, more yellow on throat and

greyer, less yellow, below; immature male at later stages shows some adult plumage features. Races vary considerably, especially in gloss colour of males: male *maforensis* has green back and golden crown, green of wing-coverts and rump slightly duller and more bluish than nominate; *cornelia* is larger than nominate, male has crown, back and rump glossed blue-green, throat glossed purple-violet; *mysorensis* is longer-billed than previous, male differing in usually having blackish, unglossed underparts, occasionally some violet gloss on throat, and is more bluish-green above than nominate; *nigriscapularis* male differs from nominate in having second and third rows of scapulars black, and velvet-black primaries; *salvadorii* is much larger than last, male has rump and edges of rectrices bluish (less greenish), and more greenish crown than nominate; *veronica* is larger than nominate, male has slightly more bluish-tinged green crown, wing-coverts and rump, underparts steel-blue; *corinna* is longer-winged but shorter-billed than nominate, male having green or blue-green gloss on crown, throat glossed purple or purple-blue, wing-coverts and rump slightly more bluish-green than nominate; *eichhorni* male has throat glossed bluish-purple, crown greyish or graphite-green, wing-coverts and rump bluer than previous; *caeruleogula* is similar to *corinna*, but much smaller wing; *vicina* male is similar to *cornelia* but throat bluish-purple (not purple), female more yellow below than nominate, immature (both sexes) has dull greyish-green (not citrine) back and pale greyish-yellow (not bright sulphur-yellow) abdomen; *christinae* is large and long-billed, male having dark green crown, throat glossed blue, female more yellow below than nominate; *porphyrolaema* male has greenish-blue confined to lesser wing-coverts and rump, with crown green or golden or slightly bronze-green, second and third rows of scapulars black, throat rich purple and laterally bordered with greenish-blue, and back and chest sooty; *grayi* male is similar to previous, but upper back and lower breast dull brownish-red (rather than sooty), purple and blue throat, and small shoulder patch blue, as is rump; *sangirensis* male also is similar, but throat bronzy with purple border, blue laterally only on chin, green crown tinged golden, wing-coverts and rump bluish, second and third rows of scapulars black, female probably has orange throat (like immature male) and pale green underparts, juvenile bright yellow underparts; *talautensis* male differs from last in having crown glossed golden-green, wing-coverts glossed blue with violet tinge, throat bronze with violet and blue border, female and immature male have brown crown, nape, back and shoulders, orange throat and upper breast more pronounced than previous, rest of underparts buffy and white; *auriceps* male is more green to golden-green on crown than nominate, darker than preceding race, with wing-coverts, rump and throat glossed blue; *auricapilla* male is similar to last, but crown very golden-green, wing-coverts and rump violet or purplish-blue; *cochrani* is slightly smaller than nominate, male having bright blue throat as *caeruleogula*, from which differs in having wing-coverts and rump bright green or blue-green with yellow suffusion, finer bill; *mariae* male resembles previous, but has throat glossed pansy-violet (not steel-blue), cap greener (but less yellow-green) than *auriceps*, wing-coverts and rump yellowish blue-green, female brighter yellow below than previous and closer in this respect to nominate; *proserpina* male has black wing-coverts, metallic greenish-blue scapulars and rump, crown green or bluish-green, throat purple or purplish-blue; *aspasioides* has longer bill than all others except *christinae*, male differs from nominate in having greenish crown, more bluish-green wing-coverts and rump, dark blue or purple-blue throat, female in having olive-grey underparts; *chlorolaema* male differs from nominate in having dark green or grass-green throat, green crown, blue-green shoulder to lower back, rump, uppertail-coverts and sides of tail. **Voice.** Song a rapid, sweet, tinkling cadence 1.5–4 seconds in duration. Calls include single, or series of, high-pitched sibilant notes; rapid series of upslurred notes followed by slow trill at lower pitch; rapid series of double notes, one higher than other; clear hollow peep; rapid, slurred, shrill "zi-zi-zi-zi-zi"; series of various single, upslurred notes; various single harsh notes; high-pitched downslurred "sweet" during foraging; flight call "pit-pit-pit".

Habitat. Various forest types, avoiding interior, including mangroves, at forest edge, in woodland, secondary growth, scrub, coconut plantations and other cultivation, also disturbed habitats and gardens. Generally in lowlands, but to 1400 m in some areas.

Food and Feeding. Various arthropods, fruit and nectar. Forages singly, in pairs and in small family groups, occasionally in larger flocks; sometimes joins mixed-species flocks. Very active. Obtains food items mostly by gleanings and hover-gleaning.

Breeding. Laying recorded in Aug and Sept in Sulawesi, Mar and May–Jan on islands of Papua New Guinea, and May on New Ireland; occupied nests late Aug to Sept and Nov in Moluccas, and juveniles Aug to early Sept on Sangihe, Talaut and Siau; in Papua New Guinea, nest-building Aug and Sept and birds with active gonads late Aug to Nov. Nest drop-shaped, c. 16–22 × 5 cm, en-

trance hole 4 × 2 cm with pronounced protecting porch on side of upper half, neatly made of fibres, bark and bast, lined with bark, fastened 3–9 m above ground to end of bough, vine, bamboo or palm frond. Clutch 2 or 3 eggs, creamy white, brown spots all over but concentrated as brown ring at broad end, or pale brownish with darker brown speckles. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Generally common throughout large range. For example, noted as being common on Togian Is, in C Sulawesi.

Bibliography. Beehler *et al.* (1986), van Bemmelen (1948), van Bemmelen & Voous (1951, 1953), Bishop (1992), Bowler & Taylor (1989a), Cheke & Mann (2001), Coates (1990), Coates & Bishop (1997), Eck (1976), Hartert (1926a, 1926b, 1926c), Holmes & Wood (1980), Indrawan *et al.* (2006), Jepson (1993a), Mayr (1936), Mayr & Diamond (2001), Mees (1965c), Rand (1942a), Riley (1997), Ripley (1959a, 1959b), Robson (1992), Watling (1983), White & Bruce (1986).

47. Copper-throated Sunbird

Leptocoma calcostetha

French: Souimanga de Macklot **Spanish:** Suimanga de Macklot
German: Kupferkehl-Nektarvogel
Other common names: Macklot's Sunbird

Taxonomy. *Nectarinia calcostetha* Jardine, 1843, Java. Genus often subsumed in *Nectarinia*. Genus names *Leptocoma* and *Chalcostetha* described simultaneously, on consecutive pages of same publication; former has been selected by First Reviser as having precedence (see page 48); present species is type of genus *Chalcostetha*. No obvious close relatives. Several races have been proposed from various islands off Sumatra, Borneo and Natunas, but none considered adequately differentiated. Monotypic.

Distribution. Extreme S Myanmar (S Tenasserim), S Thailand, S Cambodia, Cochinchina, and Peninsular Malaysia S on coasts and islands to Sumatra and satellites; W Philippines (Palawan and Balabac), Natuna Is, coasts of Borneo and islands off NE (including Maratua), and also coasts of Java.

Descriptive notes. 12.2–13 cm. Male has top of head metallic green, sides of head, hindneck, upper back, upperwing and graduated tail black, lower back, rump and upperwing-coverts metallic green; chin and throat metallic coppery red, bordered metallic purplish-blue, breast metallic purplish-blue, pectoral tufts yellow, belly and undertail-coverts black; iris brown; bill and legs black. Female has top of head grey-brown, upperparts olive-yellow, broken white eyering, throat greyish-

white, underparts greyish olive-green, more yellow on belly (extent variable), undertail-coverts white, large whitish spots on tips of rectrices becoming smaller towards centre. Juvenile is similar to female, but throat yellow, some dark scaling on throat and upper breast. **Voice.** Utters both a high trill, and a deep melodious trill; also, a disyllabic call resembling that of *Anthreptes malacensis*.

Habitat. Inhabits mangroves, heath forest, alluvial forest, secondary forest, coastal vegetation, plantations, coconut groves, cultivation and gardens close to shore; chiefly found in coastal areas, but occurs up to 915 m.

Food and Feeding. Nectar and small arthropods. Feeds on nectar of *Bruguiera* mangroves. Forages in lower and middle storeys. Very active.

Breeding. Laying calculated as Jan–Jul in Malay Peninsula, and eggs Mar–Jun, Aug–Sept and Nov in Java; occupied nest in May on Nias I (off W Sumatra); in Borneo, laying Mar–May and enlarged testes in Jun in N (Sabah) and nestlings in Jul in NW (Sarawak). Co-operative nest-building observed, and some nests may be “decoys”. Nest a pear-shaped bag, loosely woven but solid at base, with or without “tail”, with oval entrance with eave in top half, made of fine grass, fibre, kapok and hairs, camouflaged with bark, leaves and bryophytes, decorated with plant fragments, occasionally felted with spider webs or lined with egret (Ardeidae) feathers; suspended 0.7–3.5 m above ground from mangrove branch, bush, *Casuarina* branch or nipa (*Nypa*) frond, occasionally over water, total length 12.5 cm. Clutch 2 eggs, glossy, greyish-clay to warm brown, fine dark brown spots forming cap, or pale green with heavy olive-brown suffusion and variable number of dark brown spots. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Scarce in Myanmar; common to uncommon in Malay Peninsula; not uncommon in Sumatra and Borneo; uncommon in Java; common in Philippines. Destruction of mangroves has depleted populations in some areas. Occurs in some protected areas, e.g. St Paul Subterranean River National Park, in Philippines.

Genus *NECTARINIA* Illiger, 1811

48. Bocage's Sunbird

Nectarinia bocagii

French: Souimanga de Bocage **German:** Bocagenektarvogel **Spanish:** Suimanga de Bocage

Taxonomy. *Nectarinia bocagii* Shelley, 1879, Caconda, Angola.

Possibly forms a superspecies with *N. purpureiventris* and *N. tacaze*. Monotypic.

Distribution. S DR Congo (S Kasai Occidental) and Angola (highlands from Malanje, N Bié and W Lunda Sul S to Benguela and N Huila; NE Lunda Norte; Ninda, in Mexico).

Descriptive notes. Male 19 cm, 14.5–15 g; female 14 cm. Male breeding is dark iridescent violet, reflecting blue-green, above; graduated tail black, edged violet, elongated central rectrices protruding 32–35 mm beyond others; remiges black, edged dark violet, lesser upwing-coverts violet; black below, chin to upper breast dark iridescent violet, reflecting blue-green; underside of wing black; iris dark brown; bill and legs black. Non-breeding (eclipse) male in DR Congo resembles female, but retains elongated central rectrices (no eclipse plumage recorded in Angola). Female is pale olive above, more greenish on rump,

flight-feathers dark greyish-brown, edged pale olive, rest of upwing feathers fringed pale green-brown; graduated tail blackish-brown, central feathers extending up to 6 mm beyond others, underside of tail with inner webs edged pale olive, outermost rectrix with outer web all pale brown, adjacent rectrix with pale outer tip; face dark olive-brown, chin and throat olivaceous yellow, underparts olive-yellow with dark brown streaking; underwing greyish-brown on remiges, axillaries green-yellow, underwing-coverts grey with yellow tips; iris black or very dark brown, bill and legs black. Juvenile resembles female, but chin to breast grey, chin feathers tipped pale, belly pale yellow with grey patches, primaries with wider pale edging, underwing grey; immature male drab olive above with a few patches of metallic dark violet, black below with light yellow-olive patches, some violet on throat. **VOICE.** Loud “wiep-wiep” call, and “tsiek-tsiek” uttered by quarrelling males. **Habitat.** Woodlands, such as *Baikiaea plurijuga* woodland, fringes of miombo woodland and montane forest, and beside dambos. Marshy areas with flowering shrubs.

Food and Feeding. Nectar, probably also insects. Feeds from mistletoes (Loranthaceae), *Erythrina* and *Sabicea africana*. Forages singly and in pairs; sometimes in larger groups in dry season.

Breeding. Laying in Feb in Angola and Jan and Oct in DR Congo. Male courts female in fast zigzagging flights. Large nest composed of fibres, lined with soft woolly material from raffia palm (*Raphia*) trunks, constructed in small raffia palm in drier part of marshland. Clutch 2 eggs, whitish, heavily stippled with brown-grey spots, mostly at wider end. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Uncommon to locally common.

Bibliography. Benson & Irwin (1967), Benson *et al.* (1971), Cheke & Mann (2001), Dean (2000), Fry *et al.* (2000), Hall (1960), Hall & Moreau (1970), Lippens & Wille (1976), Ripley & Heinrich (1966), Schouteden (1959), Wille (1964).

49. Purple-breasted Sunbird

Nectarinia purpureiventris

French: Souimanga à ventre pourpre **Spanish:** Suimanga Pechipúrpura
German: Purpurbauch-Nektarvogel

Other common names: Rainbow Bird

Taxonomy. *Cinnyris purpureiventris* Reichenow, 1893, Migere, western Mpororo = south-western Uganda.

Possibly forms a superspecies with *N. bocagii* and *N. tacaze*. Monotypic.

Distribution. Albertine Rift mountains in E DR Congo, SW Uganda, Rwanda and Burundi.

Descriptive notes. Male 22 cm, 10–13.5 g; female 14 cm, 10–12.5 g. Male breeding has crown and side of head iridescent black, reflecting purple, hindneck and mantle iridescent green, uppertail-coverts copper-green, otherwise a mixture of iridescent black, purple, copper and green above; upperwing black, tertials and greater wing-coverts with copper-green edges, lesser coverts iridescent purple with blue sheen; graduated tail black with green edges, central feathers protruding 70–115 mm beyond others; chin and throat black, reflecting blue-green, breast purplish or coppery green, iridescent blue band on lower breast; iridescent

purple with blue sheen on belly and flanks, vent black, undertail-coverts purple, underwing black; iris dark brown; bill and legs black. Male eclipse plumage (acquired by some males periodically) lacks much of the metallic feathering on head and body, looks very like young male (from which separable in hand by speckled, opaque, skull); new olive or grey feathers then sprout on head, back and side of breast, and wing and tail feathers are moulted, looking like female but with metallic feathers on mantle. Female has crown and neck pale brown-grey, barred black, otherwise dull olivaceous green above apart from slightly yellower uppertail-coverts, wing grey-brown with olive-green edges, median and lesser wing-coverts all olive-green, and graduated tail dark grey-brown, feathers edged olive-green, outer pairs with paler grey tips, central rectrices protruding c. 5 mm;

side of head greyish-brown; pale grey with dark barring below, washed olive-yellow, especially on breast, underwing-coverts grey, edged olive-green, axillaries more greenish; iris dark brown, bill and legs black. Juvenile male is like adult female but with dark spots on foreneck, some iridescent feathering may appear within 4 months of fledging. **VOICE.** Song an explosive and rapid series of wheezy notes, squeaks and twitters. Calls include “tsi-tsi-tsi-tsi”, “zay-zay-zit-zit-zit-zit” and “ts-wick”.

Habitat. Forest edge, clearings and roadsides in montane forest and gallery forest, above 1750 m; to 2700 m in Uganda. Descends seasonally from 2350–2500 m to 1750–2000 m in response to timing of flowering at different altitudes.

Food and Feeding. Insects and nectar. Foodplants include *Albizia gummifera*, *Erythrina*, *Lobelia giberroa*, *Symphonia gabonensis* and vines; favours flowers particularly of *Symphonia globulifera*, around which it defends feeding territories. Forages singly or in small groups; also in mixed-specied flocks. Energetic forager at flowers; also catches insects in flight.

Breeding. Laying recorded in Apr–Aug and Nov in DR Congo, Sept–Nov in Uganda, and Jan–Feb in Rwanda. Territorial male sings from perch, holding head raised, wings drooping and fanned tail nearly vertical. Nest a compact oval, sometimes with “beard” of lichens 17 cm long, made of mosses, lichens, grass-heads and flower stalks, adorned with lichens and grass-heads, lined with down from *Gynura vitellina* and a few feathers, suspended from bush or tree branch 2–4 m up. Clutch 1–2 eggs, grey with grey-olive speckles, denser and forming band near wider end; no information on incubation and nestling periods.

Movements. Seasonal movements in response to flowering patterns at different altitudes.

Status and Conservation. Not globally threatened. Restricted-range species: present in Albertine Rift Mountains EBA. Locally common.

Bibliography. Carswell *et al.* (2005), Chapin (1954, 1959), Cheke & Mann (2001), Dowsett-Lemaire (1990), Fry *et al.* (2000), Hall & Moreau (1970), Kunkel (1966), Prigogine (1971, 1972).

50. Tacaze Sunbird

Nectarinia tacaze

French: Souimanga tacaze **German:** Tacazenektarvogel **Spanish:** Suimanga de Tacazzé

Taxonomy. *Certhia tacaze* Stanley, 1814, Abyssinia = probably Tacaze River, north Ethiopia.

Possibly forms a superspecies with *N. bocagii* and *N. purpureiventris*. Two subspecies recognized.

Subspecies and Distribution.

N. t. tacaze (Stanley, 1814) – highlands of Eritrea and Ethiopia.

N. t. jacksoni Neumann, 1899 – highlands of SE Sudan, N & E Uganda, W, C & S Kenya and N Tanzania.

Descriptive notes. Male 22 cm, 12–18.3 g; female 15 cm, 12–16.2 g. Male nominate race breeding has crown, neck and mantle iridescent green, tinged with purple and bronze reflections, other upperparts more purple; upperwing black, purple iridescence on median and lesser wing-coverts; long graduated tail black with iridescent purplish sheen, central feathers protruding 35–46 mm beyond others; bronzy green below, more purple below breast, becoming black on vent; underwing-coverts and axillaries black; iris brown; bill and legs black. Male non-breeding is like female, but retains wings and tail of adult male breeding.

Female has greyish olive-brown crown and upperparts, brownish-white supercilium and pale greyish-white malar stripe, lores and ear-coverts darker than upperparts, upperwings dark brown with olive edgings; dark brown tail graduated, appearing pointed as central feathers protrude c. 5 mm, outermost rectrix brownish-white on outer edges, others with broad (T5) or narrow (T3 and T4) white tips; throat grey-brown, breast and flanks olive-grey with light blackish mottling, belly and undertail-coverts olive-yellow; bare parts as male. Juvenile is like female but centre of throat black, upperparts greyer, underparts more yellow. Race *jacksoni* male has iridescent purple plumage more pinkish, metallic colour on breast broader and extending farther down, central rectrices 48–62 mm longer than next pair, also has non-breeding plumage similar to adult female but black flight-feathers and tail (with elongated central feathers) retained, as are metallic colours on wing and uppertail-coverts and, occasionally, on tips of body feathers. **VOICE.** Song consists of a long twittering, “sweet-siuswittter tseu seet-swirsittit, tsit-tsit-tsit-chitichitichiti...” or “tew tew tew tew tew”. Calls “chup, chup, chup, seee chup chup, seee chup” and harsh chatters.

Habitat. Forest patches and clearings, grassy areas, bamboo, heathland, gardens and cultivations in highlands. Seldom below 1800 m in Ethiopia; up to 4000 m on Mt Kenya and 1800–4200 m on Mt Elgon, in Uganda; recorded down to 1650 m in S Kenya (Nairobi).

Food and Feeding. Nectar, insects, spiders (Araneae) and mites (Acarina). Food taken mostly from flowers; also catches insects in flight. Associates with giant lobelias (*Lobelia*) and *Kniphofia*; other preferred foodplants include aloes (*Aloe*), mistletoes (Loranthaceae), *Impatiens elegantissima*, *Kigelia africana*, *Leonotis mollissima* and proteas (*Protea*). Forages singly and in pairs; sometimes in large flocks outside breeding season.

Breeding. Laying recorded in May and Jul–Nov in Ethiopia and Apr, Jul and Sept in Kenya, and breeding activity Dec–Feb and Jul in Tanzania; occasionally double-brooded. Male territorial. Nest built by female, taking 3–8 days, a pear-shaped structure with side entrance near top, occasionally with short “beard” of lichen, made with dead leaves, cobwebs, lichen and dry grass, lined with feathers and woolly material, suspended usually 1.5–10 m up from thin branch or in rose bush or creepers on wall; one nest consisted of dead leaves, bark and cobwebs, lined with fluff, chicken feathers and horsehair, another was made of dead giant heath (*Erica*) strands wrapped in thick felt of pale *Usnea* lichen and adorned with light brown flaky bark, seed down, feathers, plant fibres, rootlets and grass stems, and suspended in giant heath. Clutch 1–2 eggs, green-blue with dark brown marks and indistinct pink spots; incubation by female only, period 14–17 days; chicks fed in nest by both parents, for c. 19 days; fledglings return to nest to roost for at least 6 nights. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*).

Movements. Resident at high altitudes; altitudinal migrant on lower slopes. Non-breeding visitor to lower parts of Mt Elgon during cool wet season, Jun–Aug. Very common at 2800 m in Dec, but

absent there in Jul. Leaves mountains in S Sudan when *Lobelia* species stop flowering. A few hundred (80% males) in eucalypts (*Eucalyptus*) at Kaptagat, W Kenya, on 30 May, but only a few remaining 6 days later.

Status and Conservation. Not globally threatened. Common in all parts of range; locally abundant. **Bibliography.** Baker & Baker (2007), Cheke (1971a, 1971b, 1972, 1978), Cheke & Mann (2001), Friedmann (1937), Fry *et al.* (2000), Hall & Moreau (1970), Kirchner (1981), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1945), Prinzing & Jackel (1986), Prinzing *et al.* (1989), Sheppard (1958), Zimmerman *et al.* (1996).

51. Bronze Sunbird

Nectarinia kilimensis

French: Souimanga bronzé **German:** Bronzenektarvogel **Spanish:** Suimanga Bronceado
Other common names: Bronzy Sunbird; Gadow's Sunbird (*gadowi*)

Taxonomy. *Nectarinia kilimensis* Shelley, 1885, Kilimanjaro, Tanzania. Three subspecies recognized.

Subspecies and Distribution.

N. k. gadowi Bocage, 1892 – highlands of WC Angola.

N. k. kilimensis Shelley, 1885 – highlands in E DR Congo, S Uganda, W & C Kenya, Rwanda, Burundi & N Tanzania.

N. k. arturi P. L. Sclater, 1906 – S & SE Tanzania, Malawi W of Rift Valley, E Zambia, E highlands of Zimbabwe and adjoining Mozambique.

Descriptive notes. Male 22 cm, 13.5–19.9 g; female 12 cm, 11.7–16.7 g. Male nominate race has head, neck and upperparts golden-green, copper reflections on back to uppertail-coverts; upperwing dark brown, lesser and median wing-coverts iridescent coppery green; tail blackish-brown, central pair of feathers elongated; breast to belly, flanks and undertail-coverts very dark brown or black; iris dark brown; bill dull black; legs blackish. Female is grey-olive above, with pale buff to buffish-white supercilium and malar stripe, dark brown uppertail-coverts, blackish-brown tail edged white on outer 2–3 pairs of rectrices; throat

whitish with dark streaks, underparts dark yellowish with brown streaks, undertail-coverts yellow. Juvenile is similar to female, but upperparts more olive, throat mottled grey and whitish, with yellowish at side of throat, chest with olive wash, pale yellow with few or no streaks below; immature male has some metallic feathering. Race *arturi* male has head and neck to throat coppery green, upperparts and breast iridescent green with reflections of brighter green, gold, purplish-bronze or red; *gadowi* male is deeper green on head and throat and less golden on upperparts and breast than other races, female greyer above. **VOICE.** Song variations on “jer-jooey, jer-jooey-jooey, jer-jooey-jooey, tik-tik, jer-jooey”, followed by “tyup, tyup-tyup-tyeek-tyeek”; female sometimes duets in territorial song consisting of repetitions every second of “chee-wit”. Calls include repeats of “pea-view” and “choo-ee, choo-choo” or “jer-jooey” or “dzu-wee”; alarm “chee-wit” and continuous “peep”.

Habitat. Forest edges, woodland, scrub, cultivations and gardens, preferably with trees, at 1000–2350 m.

Food and Feeding. Nectar and arthropods. Feeds on variety of plants, including mistletoes (Loranthaceae), giant lobelias (*Lobelia*), aloes (*Aloe*), *Faurea speciosa*, *Grevillea banksii*, *Halleria lucida*, *Impatiens gomphophylla*, *Kigelia africana*, *Symphonia globulifera*, and species of genera *Balthasaria*, *Canna*, *Crotalaria*, *Erythrina*, *Fuchsia*, *Kniphofia*, *Leonotis*, *Musa*, *Protea*, *Prunus*, *Spathodea*, *Syzygium* and *Tecoma*. Forages in pairs. Nectar taken from flowers by perching and by hovering; insects captured by hawking and gleaning, and spiders taken sometimes from webs.

Breeding. Laying in Feb and Mar in Angola, in all months in DR Congo, Feb, Apr–Aug and Oct–Nov in Uganda, Nov–Aug in Kenya, Jan and Mar–Oct in Tanzania, Dec in Zambia, Feb–Mar, Jun–Jul and Dec in Malawi, and Sept–May in Zimbabwe; may nest 4–5 times yearly in equatorial regions (e.g. DR Congo), taking 40–50 days for each cycle. Defends territory from any intruding sunbirds and other bird species, e.g. weavers (Ploceidae) and monarch-flycatchers (Monarchidae). Large nest of dried grass, leaves, bark, down and lichen, woven with spider webs, usually with distinct porch of fibres and grass-heads and with slight “beard” below, lined with grass inflorescences or down, suspended from branch 0.8–1.3 m up; one unusual nest of race *arturi*, suspended at 2.5 m from horizontal branch of pine tree (*Pinus*), was made entirely of dry pine needles and lined with plant down; nest sometimes reused for subsequent breeding attempts. Clutch 1–2 eggs, whitish with grey-brown or lilac spots and blotches; incubation by female only, period 14–16 days; chick or chicks brooded by female, fed by both sexes but mainly by female, nestling period 14–22 days; young roost in nest for 5–6 days after fledging, still fed by female after new nest begun, but independent after 3–4 weeks. Nests parasitized by Klaas's Cuckoo (*Chrysococcyx klaas*) and Diederik Cuckoo (*Chrysococcyx caprius*).

Movements. Apparently nomadic in relation to food supplies.

Status and Conservation. Not globally threatened. Common throughout most of range.

Bibliography. Anon. (1980b), Antikainen (1990), Baker & Baker (2007), Beesley (1972), Chapin (1954, 1978), Cheke & Mann (2001), Cunningham-van Someren (1996), Dowsett-Lemaire (1989a, 1989b, 1990), Friedmann (1937), Fry *et al.* (2000), Gardiner & Meikle (1985), Hall & Moreau (1970), Hamner (1997, 2001), Hockey *et al.* (2005), Jackson (1970), Kramer (1975), Lewis & Pomeroy (1989), Löhl (1979), Lott (1991), Lott & Lott (1991), Mees (1970b), Prinzing & Jackel (1986), Skead (1967), Swynnerton (1908), Tree (1990, 1997a), Zimmerman *et al.* (1996).

52. Malachite Sunbird

Nectarinia famosa

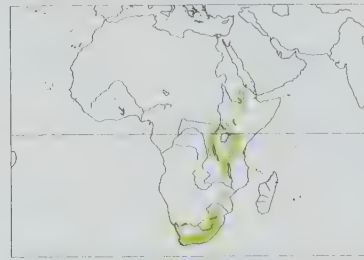

French: Souimanga malachite **German:** Malachitnektarvogel **Spanish:** Suimanga Malaquita
Other common names: Yellow-tufted Malachite/Common Malachite/Long-tailed Emerald Sunbird, Green Sugarbird

Taxonomy. *Certhia famosa* Linnaeus, 1766, Cape of Good Hope, South Africa. Possibly forms a superspecies with *N. johnstoni*. Proposed races *subfamosa* (described from Antotto, in C Ethiopia), *centralis* (Lusasa, in S Uganda) and *aneigularis* (Sotik, in SW Kenya) all considered indistinguishable from *cupreontiens*; *major* (described from Weenen, in KwaZulu-Natal) synonymized with nominate. Two subspecies recognized.

Subspecies and Distribution.

N. f. cupreontiens Shelley, 1876 – Eritrea, Ethiopia, S Sudan (Imatong Mts), E DR Congo, Uganda, Kenya, Tanzania, NE Zambia, N Malawi & N Mozambique.

N. f. famosa (Linnaeus, 1776) – E Zimbabwe and adjacent Mozambique, and S Namibia, South Africa, Lesotho and W Swaziland.

Descriptive notes. Male 24–27 cm, 12–22.5 g; female 13–15 cm, 9.1–17.5 g. Male nominate race breeding has most of body plumage bright metallic malachite-green, but rump and uppertail-coverts brighter golden-green, tertials and greater coverts edged bright green, remiges sooty black edged glossy blue; tail brownish-black, edged dark green on outer webs (except on outer rectrices), central pair of feathers protruding up to 80 mm; iris dark brown; bill and legs black.

Male non-breeding (eclipse) has metallic green

on wing-coverts, rump and uppertail-coverts, but long central tail feathers lost. Female is brown above, with grey-olive wash from neck to uppertail-coverts, tail olive-black, outer rectrices tipped and edged white, adjacent pair with white edges on outer webs, upperwing brown with yellow-olive edges on outer webs; whitish supercilium, pale yellow malar stripe; lacks pectoral tufts, has throat and breast pale yellow with brown blotches and yellow-olive wash, belly similar but less blotched and occasionally bright yellow or green-yellow; flanks olive, undertail-coverts greyish-white. Juvenile is like female, but greener upperparts and yellower underparts and malar stripe; some males have black in centre of throat. Race *cupreontiens* male has bill shorter (26–31 mm) than nominate (30–36 mm), is more golden-green above, blue colour from chest to undertail-coverts darker, less green, central tail feathers also shorter (94–120 mm) than nominate (110–151 mm), non-breeding dress similar to female but retains black remiges and tail, including elongated central rectrices (in contrast to nominate), metallic gloss on wing and uppertail-coverts and, sometimes, a few metallic tips on body feathers. **VOICE.** Song involves whistling “tseuu, tseuu” notes followed by “pesui pesui pesui” or “tik, tik, tik, tik, tik, tik, tik-heezy, heezy, heezy, heezy”; also a fast warble, sometimes interspersed with “chip” calls. Contact calls “tseuu, tseuu” or “tsi-tseer”; other calls include “ssseep” or “sseeem” or “sweenk” and “chip”; alarm a repetitive “trreecce” or slower “tjoep, tjoep, tjoep”.

Habitat. Open habitats, scrubby moorland, forest edge, *Protea* moorland and bamboo at high elevations in Kenya, Malawi and Zambia; also found in restionaceous fynbos, alpine grassland, scrub and gardens. Seldom below 2400 m in Ethiopia; to 3000 m in Tanzania; sea-level to 2800 m in South Africa, but mostly in upland fynbos.

Food and Feeding. Nectar and insects; also two small lizards recorded as prey. Food taken from plants such as giant lobelias (*Lobelia*), aloes (*Aloe*) and red-hot pokers (*Kniphofia*). Other plants visited include mistletoes (Loranthaceae), *Hagenia abyssinica*, and those of genera *Acacia*, *Buddleja*, *Digitalis*, *Erica*, *Erythrina*, *Grevillea*, *Halleria*, *Hypericum*, *Impatiens*, *Jacaranda*, *Kigelia*, *Leonotis*, *Leucospermum*, *Nicotiana* and *Protea*. Forages solitarily, in pairs and in loose groups of 30–40 individuals; also large assemblies (up to 1350 birds/ha in *Leonotis leonurus* patch) at feeding stations. Perches on specialized “rat-tail” of the South African Cape endemic rat’s-tail plant (*Babiana ringens*) to reach inflorescences and effect pollination; feeds also from *Babiana thunbergii*. Pollinaria attached to reach involved in pollination of the orchids *Disa chrysostachya* and *Disa satyriopsis*.

Breeding. Laying recorded in Jul–Sept in Ethiopia, Aug and Dec in Kenya, Mar, May and Jul–Aug in Tanzania, Jun in Zambia, Jan–Feb, Jun and Aug in Malawi, Aug–Mar in Zimbabwe, May–Feb in South Africa, Nov–Jan in Lesotho and Apr in Namibia; double-brooded, often triple-brooded. Territorial, but extra-pair copulations and cloaca-pecking occur. Male courtship involves calling, flicking of drooped wings, fast warbling and wing-flapping, sometimes with tail cocked at sharp angle and waved up and down or from side to side, and exposed pectoral tufts; male then flies vertically before hovering above female and descending to copulate; receptive female utters “pseep-pseep” calls. Male accompanies nest-building female on forays for material, nest may be completed in just 3 days but usually takes 7–30 days; nest oval, usually with porch, sometimes with “beard”, made of grass, fibres, leaves, twigs, rootlets and cobwebs, adorned with lichen or white cocoons, lined with grass, hair, feathers, down, wool and cotton, often placed (not suspended) within bush and with entrance facing inwards, but can be from near ground to 20 m up in tree or bush, often overhanging water; nest sometimes reused for further brood. Clutch 1–3 eggs, often 1 near equator, creamy or grey to brown or green-brown or green-white, freckled olive, grey or brown, dots densest at wider end; incubation by female, period 13 days; chicks fed by female, sometimes also by male, both sexes remove faecal sacs, nestling period 14–21 days; both parents feed fledglings, which return to roost in nest for up to 14 nights. Nests parasitized by Red-chested Cuckoo (*Cuculus solitarius*) and Klaas's Cuckoo (*Chrysococcyx klaas*).

Movements. Nomadic in search of flowers; recoveries up to 161 km from ringing site in South Africa. Moves altitudinally in Kenya, coming down to 1400 m; moves to higher elevations to feed on aloes during droughts in Zimbabwe, where may be nomadic after breeding. Possibly only a non-breeding visitor in S Sudan (Imatong Mts).

Status and Conservation. Not globally threatened. Common in South Africa; locally common in highlands of Kenya, Tanzania and DR Congo (1200–2800 m); uncommon in Ethiopia and Sudan.

Bibliography. Anderson *et al.* (2005), Baker & Baker (2007), Chapin (1954), Cheke (1971a, 1971b, 1978), Cheke & Mann (2001), Craig & Simon (1991), Downs & Brown (2002), Dowsett-Lemaire (1988, 1989a, 1989b), Fraser (1989, 1997b), Fraser *et al.* (1989), Fry *et al.* (2000), Hall & Moreau (1970), Hamner (2001), Hockey *et al.* (2005), Johnson & Brown (2004), Lloyd (1989), Mackworth-Præd & Grant (1945), Manning (2000), Moffet (1990), Nikolaus (1987), Oatley (1995), Porter (1956), Scammell (1963), Siegfried (1985a), Skead (1967), de Swardt (1995, 2001b, 2002, 2003), de Swardt *et al.* (2004), Symes, Downs & McLean (2001), Taylor (1946), Tree (1990), Underhill & Fraser (1989), Uys (1981b), Ward & Underhill (2006), Wolf (1975b), Wolf & Wolf (1976), van Wyk (1984), Zimmerman *et al.* (1996).

53. Red-tufted Sunbird

Nectarinia johnstoni

French: Souimanga de Johnston **German:** Lobeliennektarvogel **Spanish:** Suimanga de Johnston
Other common names: Red-tufted Malachite Sunbird, Scarlet-tufted (Malachite) Sunbird, Long-tailed Sunbird

Taxonomy. *Nectarinia johnstoni* Shelley, 1885, Kilimanjaro, Tanzania.

Possibly forms a superspecies with *N. famosa*. Race *nyikensis* formerly known as *salvadorii*, but latter name invalid, as preoccupied. Proposed race *idia* (described from Mt Kenya) treated as synonym of nominate. Four subspecies recognized.

Subspecies and Distribution.

N. j. dartmouthi Ogilvie-Grant, 1906 – E DR Congo, SW Uganda and W Rwanda.
N. j. itombwensis Prigogine, 1977 – Itombwe Mts (at 2350–3100 m), in E DR Congo.
N. j. johnstoni Shelley, 1885 – highlands of C Kenya and N Tanzania.
N. j. nyikensis Delacour, 1944 – highlands in S Tanzania, NE Zambia and N Malawi.

Descriptive notes. Male 27 cm, 14–17 g; female 14 cm. Male nominate race breeding has iridescent green crown, side of head and neck on otherwise black head, metallic green upperparts, bluish tinge on uppertail-coverts; black tail with green edges, elongated narrow central feathers protruding up to 135 mm; upperwing black, median and lesser wing-coverts iridescent green, greater coverts and alula edged iridescent bluish-green; iridescent green below, scarlet pectoral tufts, bluish-green on belly and flanks, black on thighs and undertail-coverts; underwing black; iris brown; bill and legs black. Male non-breeding (eclipse plumage) has crown and face, mantle and chin to chest dusky olive, breast and flanks brighter olive. Female has head and upperparts brownish-grey, dark brown tail has slight blue tinge, outer rectrices buff on tips and distal edges, wings blackish-brown above and below, with pale edges; throat greyish-brown with pale barring, underparts brownish-olive with dark mottling, middle of abdomen dusky white, occasionally washed with yellow, pectoral tufts one quarter the size of those of male and generally more orange (less red); bare parts as male. Juvenile is like female, but without pectoral tufts. Race *nyikensis* male has shorter wing (72–78 mm) and shorter bill (24–27 mm) than nominate (80–86 mm and 29–32 mm, respectively), female similar to nominate but slightly paler and greyer on malar, throat and middle of abdomen; *dartmouthi* male has bluish tinge in metallic green colours, bluer rump than nominate, uppertail-coverts violet-blue, shorter central rectrices (protruding up to 115 mm), violet-blue on upper belly and flanks, female more sooty above, throat markings less prominent, off-white with brownish-black mottling below, flanks dark brown, yellow wash from breast to flanks; *itombwensis* male has deeper more purple-green metallic colouring than nominate, also bluer (particularly on rump and uppertail-coverts) than previous, female paler and greyer than those two, with undertail-coverts off-white (not dull brown), middle of belly dusky brownish-white. **VOICE.** Song of nominate race begins with weak warble, followed by higher-pitched “tsk tee, tsk tee, tk tk tk”, and even higher drawn-out trill of repeated “s-s”; that of *nyikensis* starts with “tse” notes before a series of repeated “tserrep” notes. Calls include metallic “tspk”, fast “tsp-tk tsp-tk”, repeats of “tiki”, and “cha-cha” and “chk-k”. High-pitched “psurr-psurr-psurr” calls by displaying male.

Habitat. Mostly in Afro-alpine moorland; common where giant lobelias (*Lobelia*), giant groundsels (*Senecio*) and proteas (*Protea*) are present, but occurs also in *Protea* grassland and *Kotschyia-Erica* heathland, *Hagenia-Hypericum* forest, *Hypericum* scrub and bamboo. Confined to high elevations, 1900–4400 m; race *itombwensis* restricted to 2350–3100 m in Itombwe Mts (E DR Congo). **Food and Feeding.** Nectar, pollen, insects (particularly bibionid flies and chironomids) and spiders (Araneae). Food taken from giant lobelias, red-hot pokers (*Kniphofia*), aloes (*Aloe*), proteas, groundsels, heaths (*Erica*), *Hypericum* species and *Tecoma capensis*. Forages singly, in pairs and in mixed groups with other sunbirds. Active through most of day, even in adverse weather; tame. Perches freely on flowers. Catches insects in air by flycatching from bushstop. **Breeding.** Laying recorded in Dec in DR Congo, Nov–Jan in Uganda, Jan, Feb, May, Jul–Oct and Dec in Kenya, Jan in Tanzania, and Jan, Oct and Dec in Malawi. Territorial. In display, male raises bill, fluffs out feathers, raises tail over back, keeps wings partly open, and makes high-pitched calls while turning body clockwise. Oval nest composed of *Usnea* lichens or white plant material, animal hair and brown fibres, lined with pappus, placed from below 1 m to up to 15 m above ground within *Erica* bush, in *Hagenia* tree, in top of grass tussock, in *Lobelia telekii* inflorescences, or among dead leaves below terminal rosettes of *Senecio keniodendrum*; territory 1700–3300 m², size varying according to altitude. Clutch usually 1 egg, but in high-quality territory 2 (4% of nests), white with streaks of pinkish-brown, denser at wider end; incubation by female alone, precise period apparently undocumented despite reports to contrary; chicks brooded by female, usually fed by female alone but sometimes by both sexes at rate of 5–12 visits per hour, nestling period 22 days; fledglings tended by female for c. 14 days. **Movements.** Descends to lower altitudes seasonally in Kenya and N Tanzania. Migrant in Malawi, where absent from Nyika plateau in May–Jun.

Status and Conservation. Not globally threatened. Common to very common throughout range; locally abundant. **Bibliography.** Baker & Baker (2007), Burd (1995), Chapin (1954), Cheke & Mann (2001), Coe (1961, 1967), Dowsett-Lemaire (1988, 1989a, 1989b), Evans, M.R. (1991, 1996, 2003), Evans, M.R. & Barnard (1995), Evans, M.R. & Hatchwell (1992a, 1992b), Evans, M.R. & Thomas (1992), Fry *et al.* (2000), Hall & Moreau (1970), Prigogine (1977), Williams (1951b), Young (1982), Young & Evans (1993), Zimmerman *et al.* (1996).

Genus *DREPANORHYNCHUS*

Fischer & Reichenow, 1884

54. Golden-winged Sunbird

Drepanorhynchus reichenowi

French: Souimanga à ailes dorées **Spanish:** Suimanga Alidorado
German: Goldschwingen-Nektarvogel

Taxonomy. *Drepanorhynchus reichenowi* G. A. Fischer, 1884, Lake Naivasha, Kenya. Genus often subsumed in *Nectarinia*. Birds from Mt Elgon, on Kenya–Uganda border, described as race *alinderi*, but considered inseparable from nominate. Three subspecies recognized.

Subspecies and Distribution.

D. r. lathburyi (J. G. Williams, 1956) – N Kenya.
D. r. reichenowi G. A. Fischer, 1884 – W & S Uganda E to W & C Kenya, and N Tanzania.
D. r. shellyae (Prigogine, 1952) – E DR Congo.

Descriptive notes. Male 16–24 cm, 12.8–17.5 g; females 14–15 cm, 11–15.9 g. Distinctive, rather large sunbird with markedly decurved bill, large golden patches on wing and tail; both sexes have unfeathered V-shaped area on forecrown forming groove, which accumulates pollen as the bird probes in flowers, groove sometimes indistinct but increases in size with wear (becoming up to 9.5 mm long and 3.2 mm wide at its broadest point, near bill). Male nominate race breeding is black above, with bronzy-gold sheen on crown, mantle and back, duller on rump and uppertail-coverts; very long, graduated tail black, central feathers edged golden-yellow and

extending 70 mm beyond rest, which have golden only on outer webs; upperwing black, remiges broadly edged bright golden-yellow (appear all golden), median and lesser wing-coverts copper-coloured, greater coverts, primary coverts and alula edged golden-olive; black below, copper and golden sheen on chin and breast, underwing black; iris dark brown; bill and legs black. Male non-breeding (eclipse plumage) has dull black in place of glossy bronze on head, foreneck and back, a few metallic feathers on lower foreneck and back. Female is olive-green with brown mottling above, but crown, lores and ear-coverts dark brown, dark brown tail edged golden-yellow and graduated, central rectrices extending up to 10 mm beyond others, wing brown with yellow edges (looking all yellow when folded); chin and throat pale yellow, underparts dark olive-yellow, heavy dark brown mottling on centre of abdomen; bare parts as male. Juvenile is like adult female, but underparts olive with extensive black barring, has black face, chin and throat, and less bright yellow edges on remiges and rectrices. Race *lathburyi* is smaller (wing 75–80 mm) than nominate (79–86 mm), with bill more curved; *shellyae* has bill less curved than nominate, female crown grey. **Voice.** Chattering song includes bursts of twitters mixed with high “chi-chi-chi” notes. Calls include quiet “jwee” and “tweep” notes, fast repetition of “cha” and rapid “chuk-chi-chi-chek, cher-cher-cher”.

Habitat. High-lying areas with grassland, montane forest and bamboo clearings, also gardens and agricultural areas; at 1170–3300 m.

Food and Feeding. Insects, including beetles (Coleoptera), Hymenoptera and flies (Diptera), and nectar. Forages singly, in pairs and in groups, sometimes in very large flocks. Takes insects and nectar from plants such as aloes (*Aloe*), *Erythrina abyssinica*, *Fuchsia* species, *Ipomoea batatas*, *Jacaranda mimosifolia*, *Leonotis* species and mistletoes (Loranthaceae). Catches alate ants in flight. Adopts feeding territories in *Leonotis nepetifolia*. Acquires yellow coating of pollen on crown when feeding on lion’s claw flower (*Crotalaria agatiflora*).

Breeding. Egg-laying recorded in May in DR Congo, Jan and Oct in Kenya and Feb and Apr in Tanzania. Globular nest, some with porch and others without, constructed variously with grass, flower stalks. *Usnea* lichens and gossamer, lined with plant down, placed 1 m or more up in *Leonotis* plant, on top of thistle or in shrub. Clutch 1 egg, whitish, heavily mottled with grey-brown, spots denser at wider end; no information on incubation and nestling periods.

Movements. Seasonal altitudinal movements of up to 1000 m or more in response to flowering regimes; one female recovered 101 km from ringing site.

Status and Conservation. Not globally threatened. Common throughout range.

Bibliography. Backhurst (1973, 1977), Baker & Baker (2007), Chapin (1954), Cheke & Mann (2001), Friedmann (1937), Friedmann & Stager (1969), Fry *et al.* (2000), Gill & Wolf (1975a, 1975b, 1977, 1978, 1979), Hall & Moreau (1970), Lewis & Pomeroy (1989), Lott (1991), Prigogine (1952, 1971), Pyke (1979), Sheppard (1958), Travis (1982), Williams (1956), Wolf (1975a), Zimmerman *et al.* (1996).

Genus *CINNYRIS* Cuvier, 1816

55. Olive-bellied Sunbird

Cinnyris chloropygius

French: Souimanga à ventre olive **Spanish:** Suimanga Ventríoliva
German: Olivbauch-Nektarvogel

Taxonomy. *Nectarinia chloropygia* Jardine, 1842, Aboh, Nigeria. Genus often subsumed in *Nectarinia*. Race *bineschensis* poorly differentiated from, and sometimes synonymized with, *orphogaster*; moreover, it is isolated from other races of present species, and has been suggested also as being possibly misidentified *C. reichenowi*. Proposed races *luhderi* (described from Bipindi, in Cameroon) and *insularis* (Bioko) synonymized with nominate; *uelliensis* (Koloka, Angu and Amadi, on R Uelle, in DR Congo) merged with *orphogaster*. Females in Cameroon and DR Congo having light yellow pectoral tufts and red breastband but no metallic plumage described as race *ogilviegranti*, but shown to be aberrantly plumaged females of nominate race. Four subspecies recognized.

Subspecies and Distribution.

C. c. kempi Ogilvie-Grant, 1910 – Senegal E to SW Nigeria.
C. c. chloropygius (Jardine, 1842) – Bioko I (Fernando Póo) and SE Nigeria E to S Chad and Central African Republic, S to NW Angola and W DR Congo.
C. c. orphogaster Reichenow, 1899 – C & E DR Congo and S Sudan S to NE Angola, Rwanda, Burundi, Uganda, W Kenya and W Tanzania.
C. c. bineschensis Neumann, 1903 – SW Ethiopia.

Descriptive notes. 10.5–11 cm; male 4.7–8 g, female 5–7.5 g. Male nominate race is metallic green on head and throat and from crown to uppertail-coverts; upperwing brown, secondaries narrowly edged olive, tail black with dark blue sheen; blue band below throat merges into scarlet breastband (10 mm wide), otherwise olive below, pectoral tufts bright yellow; underwing off-white, washed yellow or grey; iris brown; bill and legs black. Female is olive above, with pale supercilium, dark stripe through eye, brown flight-feathers and wing-coverts edged green-olive, tail black with dark blue sheen; chin off-white, throat pale olive,

underparts olive-tinged yellow; bare parts as male. Immature male resembles female, but more brown above; some subadult males retain white underwing-coverts from immature plumage, even when iridescent feathers present, and thus confusable with *C. minullus*. Race *kempi* male is lighter, more olive, below and has narrower, more orange breastband than nominate; *orphogaster* male has darker abdomen than nominate; *bineschenis* is like previous, but male abdomen is darker, more sooty-coloured. **Voice.** Short song 3–4 seconds, beginning with “pisr-pisr”, then fast rising and falling notes, “sisisisisi-sisisisi-si”, and other warblings. Calls include repetitions of “chip”; also “zit-zit, zeet-zeet” or “psee”.

Habitat. Clearings in forest, cultivations, gardens, well-wooded savanna, coastal thickets and mangroves.

Food and Feeding. Insects, spiders (Araneae), nectar, seeds and bits of flowers. Forages mostly in pairs or small groups. Visits *Cogniauxia podolaena*, *Manihot esculenta*, *Manihot utilissima*, *Occhiothosmus africanus*, *Psidium guajava*, *Spathodea nilotica*, *Thevetia peruviana*, *Touracanthus africanus*, and flowers of genera *Bongainvillea*, *Canna*, *Clerodendrum*, *Coffea*, *Erythrina*, *Heliconia*, *Hibiscus*, *Ipomoea*, *Maerua*, *Musa*, *Solanum* and *Yucca*. Robs flowers of nectar, and hovers in front of flowers.

Breeding. Laying recorded in Oct–Nov in Sierra Leone, Feb and Nov in Liberia, Dec in Ivory Coast, Feb, Apr and Sept–Oct in Ghana, May–Oct in Nigeria, Feb–Jun, Aug–Dec in Cameroon, Sept in Bioko, Aug and Dec–Mar in Gabon, Jan and Sept–Oct in DRCongo, in all months except May and Jul in DRCongo, Jul in Ethiopia, Feb–Mar, Jul–Sept and Nov in Uganda, Nov in Tanzania, and Mar and Dec in Angola. Untidy oval nest made of grass, bark and leaves, with short messy “beard” and porch, lined with grass, plant material, feathers and/or wool, attached 1–10 m up on branch of bush or palm. Clutch 1–3 eggs, long pointed oval, white or grey, with grey blotches or stripes and grey or brown spots concentrated at wider end; incubation by female only, chicks fed by both parents; no information on duration of incubation and nestling periods. Nests parasitized by African Emerald Cuckoo (*Chrysococcyx cupreus*) and Western Green-backed Honeyguide (*Prodotiscus insignis*).

Movements. Partial migrant in W Africa, where some travel N at start of rainy season.

Status and Conservation. Not globally threatened. Generally common throughout much of range, but rare in Ethiopia and Sudan. Occurs in several protected areas, e.g. Korup National Park, in Cameroon.

Bibliography. Ash (1994), Atkins (1994), Baker & Baker (2007), Bannerman (1921a), Bates (1927), Borrow & Demey (2001), Brosset & Énard (1986), Butten (1967), Carroll (1988), Chapin (1954), Cheke & Mann (2001), David & Gosselin (2002b), Eizentraut (1963), Fry *et al.* (2000), Hall & Moreau (1970), Lachenaud (2006a, 2006b), Lewis & Pomeroy (1989), Mariaux & Vanher (1991), Nikolaus (1987), Prendergast (1983), Prigogine (1971, 1972, 1978b), Rand *et al.* (1959), de Roo-de Ridder & de Roo-de Ridder (1969), Seric (1957), Traylor & Parelus (1967), Waltert & Faber (2000), Zimmerman *et al.* (1996).

56. Tiny Sunbird
Cinnyris minullus

French: Souimanga minule **German:** Zwergnektarvogel **Spanish:** Suimanga Enano

Taxonomy. *Cinnyris minullus* Reichenow, 1899, Yaoundé, Cameroon. Genus often subsumed in *Nectarinia*. Supposedly larger birds from Bioko I described as race *amadoni*, and others, from R Luulaba, in DRCongo, described as race *marginatus*; both, however, fall within range of variation of populations elsewhere in species’ area of distribution. Monotypic. **Distribution.** Sierra Leone E to Ghana, and S Nigeria, Bioko I (Fernando Póo) and Gabon E to DRCongo and W Uganda.

Descriptive notes. 9–10 cm; 4.5–6.5 g. Male has head, chin, upper throat and upperparts metallic green, bluer on uppertail-coverts; upperwing very dark brown, greater wing-coverts narrowly edged metallic green, lesser and median coverts metallic green; tail black with metallic blue-purple wash; thin iridescent blue band on lower throat, above scarlet breastband with many metallic blue patches within it; pectoral tufts yellow, dark olive belly and below; inner borders of undersides of flight-feathers greyish-white, axillaries yellowish-white, underwing-coverts white; iris dark brown; bill and legs black. Female is dark olive-green above, with narrow olivaceous-yellow supercilium, dark line through eye, dark brown remiges edged dark yellowish and wing-coverts edged olive-yellow, tail very dark brown with blue gloss, outer rectrix paler, throat grey or dusky olive-green, flecked whitish, underparts olive with yellow wash, yellow most obvious on belly; underwing-coverts and axillaries as male; iris very dark brown, bill black but paler proximally, base of lower mandible yellowish, legs black. Juvenile is similar to female, but with dark grey throat bib (whitish-grey at margins), supercilium shorter and less distinct, underparts washed bright yellow, gape pink-tinged orange-yellow. **Voice.** Song a high-pitched succession of squeaky “tsi-tsi-tsi” or “suisui-sui-sui”, for c. 15 seconds, or shorter burst of “tsi” or “twee”, before a warble including “chip” notes, for 2–3 seconds. Calls “chip” or “chip-chip”.

Habitat. Occurs in mature or secondary forest, forest edges and clearings, and forest savanna mosaic; also found in gardens, cocoa plantations, abandoned agricultural fields, and around villages in forest.

Food and Feeding. Nectar, pollen and small insects. Forages singly and in pairs; joins mixed-species flocks in upper strata of forest. Visits flowers of *Anthoecista*, *Delonix regia*, *Leca*, *Maranthus*, *Mussaenda* and creepers.

Breeding. Egg-laying recorded in Apr–Jun and Oct in Cameroon and Mar, Jun and Dec in DRCongo, and occupied nests in Sept and Nov in Gabon. Small, ovoid nest 13 cm tall, 7.5 cm wide, side entrance 2.5 cm wide sited 9 cm below top, with porch of *Marasmius*, nest always includes bark, and is well made with rootlets of epiphytes, grass stems and dead leaves, held together with cobwebs and filaments of *Marasmius* fungus, lined with kapok, fine grass or pappus, and decorated with bark, lichen, dry leaves or flowers; placed 1.5–3 m up on leafy branch in tree; site sometimes reused in successive years. Clutch 1–2 eggs, long oval, white with green or blue tinge, heavily marked with grey-brown or dark brown spots, or with irregular grey or dark lilac-grey blotches concentrated at wider end; incubation by female alone, both sexes feed nestlings; no information on duration of incubation and nestling periods.

Movements. No data.

Status and Conservation. Not globally threatened. Locally common; rare in Nigeria and mainland Equatorial Guinea; scarce in Uganda, mostly restricted to W forests. Widespread and not uncommon in Gabon, where 2–3 birds/10 ha. Occurs in several protected areas.

Bibliography. Amadon (1953), Bannerman (1948, 1951), Bates (1911), Borrow & Demey (2001), Brosset & Énard (1986), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Christy & Clarke (1994), Eizentraut (1965, 1973), Fry *et al.* (2000), Hall & Moreau (1970), Pérez del Val (1996), Prigogine (1971, 1972), Rand *et al.* (1959).

57. Miombo Double-collared Sunbird
Cinnyris manoensis

French: Souimanga du miombo **German:** Miombonektarvogel **Spanish:** Suimanga del Miombo
Other common names: Miombo/Double-collared Sunbird; Pinto’s Double-collared Sunbird (*pintoi*)

Taxonomy. *Cinnyris manoensis* Reichenow, 1907, Langenburg (= Missale), Malawi. Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. chalybeus*, and sometimes considered conspecific. Recent work indicates that *pintoi* is probably best treated as a separate species; occurs in sympatry with nominate along Muchinga Escarpment in Zambia; apparent ecological separation in the same zone, *pintoi* occupying pure miombo, with nominate found more towards rocky edge habitat with aloes; eggs and nest reported to be recognizably different from those of nominate; also, consistent morphological differences, with no evidence of intergradation. An as yet undescribed taxon, apparently close to present species or to race *whytei* of *C. ludovicensis*, occurs in NE Zambia and Tanzania; may belong with either of these species or represent a distinct species (see page 201). Race *pintoi* formerly referred to by name *intermedius*, but that name is preoccupied. Other proposed races are *gertrudis* (described from Songea, in S Tanzania), *namwera* (Mangoche Mts, in S Malawi), *zonarius* (Zobuc, in border region Malawi–Mozambique) and *bractatus* (Fort Chiquaquia, in N Zimbabwe), all synonymized with nominate. Three subspecies currently recognized.

Subspecies and Distribution.

C. m. pintoi (Wolters, 1965) – C Angola, S DRCongo, SW Tanzania, Zambia (W of Luangwa rift) and N Malawi (N of Ntchisi).

C. m. manoensis Reichenow, 1907 – C & W Tanzania (also isolated populations in N), E Zambia, Zimbabwe, S Malawi (S of Ntchisi) and N Mozambique.

C. m. amicornum (Clancey, 1970) – Mt Gorongosa, in S Mozambique.

Descriptive notes. 13 cm; 6.8–12.8 g. Male nominate race is metallic green with bronze reflections from head to lower back and from chin to upper breast; rump pale olivaceous brown, tips of uppertail-coverts iridescent blue; upperwing greyish-brown, lesser wing-coverts metallic green; tail slightly glossy dark brown, outer rectrix paler and with greyish-white on outer margin; narrow (2 mm deep) violet-blue band above larger (10 mm deep) scarlet band on lower breast; pectoral tufts yellow, belly and vent pale olivaceous; underwing-coverts dull white, axillaries washed yellow; iris dark brown; bill and legs black. Female is greyish-brown on head and upperparts, with dusky brown lores, rump washed with olive, wing greyish-brown, edged pale brown; brownish-grey with some speckles below, belly paler with slight yellow wash, bare parts as male. Juvenile is similar to female. Race *amicornum* is slightly larger than nominate, male greener above, upper breastband more violet and belly darker, female darker above and browner below than nominate; *pintoi* male has uppertail-coverts greyish or narrowly tipped glossy green (without blue or violet), underparts paler grey, and bill shorter and finer than nominate, juvenile similar to female but more olive, male gains adult dress only at end of third year, until when retains many dull olive feathers above and on breast, red and blue chestbands are irregular, and no white on tail. **Voice.** Song a short descending trill and a complicated warble, in bursts of 7–8 seconds, of rising and falling “tsee-see-tsee-tsee”, usually preceding “chip-chip”. Latter also as call; other calls are variations of “zit”, or “zip-chip-chip-chip” or “zip-chip”.

Habitat. Miombo woodland, savanna, riverine woodland, gardens and parks; also thorn-scrub and highland *Leucospermum* areas in Zimbabwe, where reaches 1500 m; found in *Cryptosepalum* forest in Zambia.

Food and Feeding. Nectar, insects, also spiders (Araneae). Takes nectar from flowers of low-growing plants such as aloes (*Aloe*) and species of *Leonotis*, *Hibiscus* and *Kniphofia*, and from flowers of trees such as *Bauhinia*, *Brachystegia speciformis*, *Fauarea saligna*, *Erythrina abyssinica*, eucalypts (*Eucalyptus*) and *Jacaranda mimulopsis*, and from mistletoes (Loranthaceae). Hawks for insects; gleans for invertebrates among mopane trees (*Colophospermum mopane*). Males defend feeding areas from both conspecifics and other species; dominant over *C. talatata* and *C. bifasciatus* at *Cassia singuena* trees. Drinks from birdbaths.

Breeding. Egg-laying recorded in Sept in Tanzania, Aug and Oct–Nov in Zambia, May–Nov and Jan–Feb in Malawi, May in Mozambique, and all year (mainly Sept–Nov) in Zimbabwe. Male displays include swinging upside-down on perch while singing to female carrying nest material; partners perform pivoting actions and face-to-face bowing on perch. Pear-shaped or spherical nest made of grass, cobwebs or plant down, in Zambia of *Usnea* lichen, 2–6 m up on bush, attached by twigs through top of dome; sometimes on house verandah. Clutch 1–3 eggs, pinkish-white, dull grey or light brown with brown streaks along length of egg or brown blotches, in Zambia plain olive or chocolate-coloured; incubation period 14–16 days; nestling period 13–15 days. Undescribed form (possibly belonging to present species or *C. ludovicensis*, or a distinct species) has been found breeding in NE Zambia: nest made of grass; eggs pale and freckled.

Movements. Resident in some areas. Nomadic in Zimbabwe, where ascends to higher altitudes in droughts. One individual recovered 29 km from ringing site. Shifts to seek flowering plants.

Status and Conservation. Not globally threatened. Common in Malawi and Zimbabwe; locally common in Angola; uncommon in Tanzania and Zambia. Occurs in some protected areas; e.g. in Malawi found in Lilongwe Nature Sanctuary and Dzalanayama Reserve.

Bibliography. Baker & Baker (2007), Chapin (1954), Cheke & Mann (2001), Fry *et al.* (2000), Hamner (1997, 2001), Haugard (1995), Hoeky *et al.* (2005), Lane (1992), Macdonald (1958), Manson (1986), Shaw (2001a), Tarboton (2001), Tree (1990, 1997d, 2001), Vincent (1949).

58. Southern Double-collared Sunbird
Cinnyris chalybeus

French: Souimanga chalybée **German:** Halsbandnektarvogel **Spanish:** Suimanga Acerado
Other common names: Lesser/Smaller/Grey-bellied Double-collared Sunbird, Red-collared Sunbird

Taxonomy. *Certhia chalybea* Linnaeus, 1766, Cape of Good Hope, South Africa.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. manoensis*, and sometimes considered conspecific. Additional proposed races in South Africa are *capricornensis* (described from Soutpansberg, in Limpopo Province), synonymized with *subalaris*, and *albilateralis* (from Port Nolloth, in W Northern Cape), considered inadequately differentiated from nominate. Two subspecies recognized.

Subspecies and Distribution.

C. c. chalybeus (Linnaeus, 1766) – S Namibia and W South Africa (Northern Cape, Western Cape).
C. c. subalaris Reichenow, 1899 – E South Africa (Limpopo Province S to Eastern Cape) and Swaziland.

Descriptive notes. 12 cm; 6–10 g. Male nominate race breeding is metallic green on head, throat, upper breast, neck, mantle, back and rump; uppertail-coverts iridescent bright blue, tail black with blue sheen, outer web of outer rectrices whitish; upperwing and primary and greater wing-coverts dark brown, lesser coverts metallic green; green of upper breast bordered below by narrow band (2 mm deep) of iridescent bluish-violet, and under this a scarlet breastband 8–10 mm deep; yellow pectoral tufts, upper belly smoky grey, lower belly, flanks and undertail-coverts paler olive-grey, underwing-coverts pale brown; iris dark brown;

bill and legs black. Male non-breeding (eclipse plumage) is similar to female, but wings and tail as breeding male, metallic colours on mantle to uppertail-coverts and a few on head, chin and throat, and some red feathering on lower breast. Female has crown and nape grey-olive, upperparts grey-brown, washed olive on mantle and upperwing-coverts, pale yellow on bend of wing, tail blackish-brown, paler on outermost feathers, which have whitish outer web and tip; throat and breast olive-grey, sometimes with diffuse streaking, belly and undertail-coverts greyer, axillaries and underwing-coverts pale greyish-yellow; bare parts as male, buccal cavity orange (changing to pink when ready to lay). Juvenile as female; immature male similar to adult but with some olive feathering within metallic plumage, also has eclipse plumage with brown head and only 10–30% of feathers (mostly on nape) glossy green. Race *subalaris* male is darker grey, more olive-tinged, on abdomen than nominate, bill slightly longer (24–26 mm; nominate 21–23 mm), female generally greener and darker above. **VOICE.** Song starts and finishes with a series of 6–12 harsh “ptzzer” or “ssssweee” hisses, and is otherwise a warble of rising and falling “tsee” and a distinctive rising “weeto-weeto-weet” intermixed with rising and falling “weeta witta witta-weeta, witta witta, witta witta wit” and variants. Female also has subsong, indistinguishable from that of males. Calls include “cher-cher”, “swik-swik”, “chee-chee”, “zz, zz, zz, zhik” and a plaintive “tseet”.

Habitat. Varied, including scrub, gardens, fynbos, plantations, protea (*Protea*) areas of highlands and dune thickets; woodland and coastal, inland and evergreen montane forests.

Food and Feeding. Nectar, insects, spiders (Araneae); probes fig fruits (*Ficus*). Associated with the milkweed *Microlooma sagittatum*; the birds collect its pollinia, which become attached to the tongue by slotting into a specialized groove. Visits wide range of other foodplants, including *Brunsvigia orientalis*, *Burchellia bubalisia*, *Canna indica*, *Erythrina lysistemon*, *Erythrina tomentosa*, *Grevillea banksii*, *Halleria lucida*, *Justicia guttata*, *Kniphofia rhodesiana*, *Kniphofia uvaria*, *Lachenalia viridiflora*, *Lachenalia pendula*, *Manihot glaziovii*, *Pelargonium inquinans*, *Phygelius capensis*, *Schotia afra*, *Tecoma capensis*, species of genera *Aloe*, *Bauhinia*, *Cadaba*, *Callistemon*, *Carissa*, *Erica*, *Eucalyptus*, *Gladiolus*, *Lantana*, *Leonotis*, *Leucospermum*, *Lycium*, *Musa*, *Nicotiniana*, *Protea*, *Prunus*, *Salvia*, *Strelitzia*, and mistletoes (Loranthaceae). Hovers in front of flowers, and nectar-robs others. Hawks for insects.

Breeding. Egg-laying Apr–Dec in South Africa; sometimes double-brooded. Territorial. Males may sing from perches for 15 minutes or more, sometimes flashing pectoral tufts at each other; sometimes sings on the wing, and conducts wing-clapping display; male often pecks cloaca of female, usually before mating. Nest built by female, taking 1–4 weeks to do so (one nest built in a week, with peak rate of 39 visits per hour), compact and pear-shaped or oval, constructed with grass, lichen, wool, feathers, twigs and cobwebs, sometimes with porch over entrance, covered externally with cobwebs, lined with feathers, hairs, plant down or (in upland areas) *Usnea* lichen, usually without “beard” but one nest had dangling beard of *Usnea*, can be sited less than 0.2 m above ground, but usually c. 1.5 m up in ericaceous or other shrub and occasionally up to 8 m up (e.g. in *Podocarpus falcatus*); nest sometimes reused. Clutch 1–3 eggs, creamy to grey-white or green-white, densely covered with brown, grey, sepia or black mottles, lines and spots; incubation by female, period 2 weeks; chicks brooded by female, fed by both parents, both also remove faecal sacs, which may be passed to them by 10-day-old nestlings; nestling period 15–19 days; fledglings return to nest to roost for up to 9 nights, remain with parents for up to c. 1 month. Nests parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*).

Movements. Recoveries up to 34 km from where ringed suggest dispersion in search of food, and post-breeding movements indicated by regular times of arrival and departure at some sites. Leaves arid W areas in Jul–Dec, moving into S Eastern Cape May–Nov. Appears suddenly in synchrony with blooming of aloes (*Aloe*).

Status and Conservation. Not globally threatened. Common to fairly common or locally common throughout range.

Bibliography. Brieschke (1991), Cheke & Mann (2001), Chenaux-Repond (1975), Clancey & Irwin (1978), Compton *et al.* (1996), Follet (1990), Fraser (1989, 1997d), Fraser *et al.* (1989), Fry *et al.* (2000), Hall & Moreau (1970), Hockey *et al.* (2005), Keast (1968d), Leon & Nicolson (1997), Lotz & Nicolson (1996), Martin (1983), Martin *et al.* (1991), McCardle (1989), Mortimer & Martin (1991), Oatley (1995, 1997), Pauw (1998), Rebelo (1987b), Schmidt (1964, 1991), Skead (1967), Swynnerton (1916), van Tets & Nicolson (2000), Tree (2001), Uys (1981a), Vincent (1949), van Zijl (1999).

59. Neergaard's Sunbird

Cinnyris neergaardi

French: Souimanga de Neergaard **Spanish:** Suimanga de Neergaard
German: Neergaardnektarvogel
Other common names: Coguno Double-collared Sunbird

Taxonomy. *Cinnyris neergaardi* C. H. B. Grant, 1908, Coguno, Mozambique. Genus often subsumed in *Nectarinia*. Monotypic.

Distribution. SE Mozambique (Beira area S to Inhambane, and S from Maputo) and NE South Africa (coastal belt S to S of Richard's Bay, in KwaZulu-Natal).

Descriptive notes. 10–11 cm; male 6.2–7.1 g, female 5.6–5.9 g. Male has head, throat and upperparts, including median and lesser upwing-coverts, iridescent bright green, uppertail-coverts bright blue, tail dark brownish-black; remiges, primary coverts, alula and greater wing-coverts black; thin iridescent blue band beneath green throat; breast scarlet, thinly speckled with blue, pectoral tufts yellow, belly and undertail-coverts dull black, axillaries also black, underwing-coverts brown; iris dark brown; bill and legs black. Female is grey-brown above, rump more olive, rectrices dark brown, outer pair paler, particularly on outer webs, has narrow buff-white supercilium, dark grey-brown side of head; remiges dark grey-brown, primaries edged greyish-white, secondaries, tertiaries and greater wing-coverts with broader pale grey-brown edges, lesser and median coverts grey-brown; pale grey-brown below, lightly tinged yellow on lower breast and belly, underwing-coverts and axillaries off-white; bare parts as male. Juvenile is similar to female. Voice. Song consists of repetitions of sequence involving “tsui-tsui” followed by rapid burst of “ti-ti-ti-ti...”, for 1–3 seconds.

Habitat. Coastal scrubland, particularly dry sandy thornbush and woodland, clearings, and villages inland.

Food and Feeding. Nectar, small insects, and spiders (Araneae). Takes nectar from aloes (*Aloe*), *Ceroiops tagal*, *Schotia capitata* and *Syzgium cordatum*. Associates with *Chalcomitra amethystina*.

Breeding. Egg-laying in Sept–Jan in Mozambique and Jul, Oct and Nov in South Africa. Territorial males sing from tops of trees. Bulky nest, made of fibres and feathers, camouflaged with insect larvae, lined with white fibres from seedpods of the creeper *Strophanthus lucidus*, hidden in thick clump of *Usnea* lichen or suspended 5–6 m up in *Acacia burkei* tree. Clutch 2 eggs, dull brown with blackish spots and blotches. No other information.

Movements. Present in extreme S Mozambique only in austral summer, indicative of nomadism in non-breeding season.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in South-East African Coast EBA. Not uncommon, but restricted to dry woodland and forest on sandy soil. Coastal habitat threatened by deforestation and by afforestation with non-native species in Mozambique. Occurs in Mkuze Game Reserve, in South Africa.

Bibliography. Anon. (1980a, 2007), Butchart & Stattersfield (2004), Cheke & Mann (2001), Chittenden (1995), Clancey (1952, 1964, 1971), Fry *et al.* (2000), Hall & Moreau (1970), Hockey *et al.* (2005), Johnson (1997), Skeud (1967), Stattersfield & Capper (2000), Tarboton (2001).

60. Stuhlmann's Double-collared Sunbird

Cinnyris stuhlmanni

French: Souimanga de Stuhlmann **Spanish:** Suimanga de Stuhlmann
German: Stuhlmann-Nektarvogel
Other common names: Rwenzori Double-collared Sunbird

Taxonomy. *Cinnyris stuhlmanni* Reichenow, 1893, West Rwenzori, DR Congo.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. prigoginei* and *C. ludovicensis*; sometimes treated as conspecific with first of those. Has been considered conspecific also with *C. afer*, and is closely related to *C. reichenowi*. Four subspecies recognized.

Subspecies and Distribution.

C. s. stuhlmanni Reichenow, 1893 – Rwenzori Mts, in NE DR Congo and W Uganda.
C. s. chapini Prigogine, 1952 – mountains of E DR Congo from W of L Edward (Nord-Kivu District) S to NW of L Tanganyika (Mt Kabobo, in Sud-Kivu).
C. s. graueri Neumann, 1908 – mountains S & E of L Edward (E DR Congo and SW Uganda) S to N tip of L Kivu (Virunga Volcanoes and NW Rwanda above 1800 m).
C. s. schubotzi Reichenow, 1908 – mountains of Nyungwe Forest, in SW Rwanda (S L Kivu), and W Burundi (mountains NE of Bujumbura).

Descriptive notes. 13–14 cm; 6–11.5 g. Male nominate race breeding has head to upper breast and upperparts, including scapulars and lesser and median wing-coverts, metallic emerald-green, uppertail-coverts metallic violet-blue, tail very dark brown with white tips and narrow white edges on two outer feather pairs, graduated, central feather pair 13 mm longer than outer feathers; upperwing mostly dark brown, feathers more olivaceous on edges; lower breast with thin (3 mm deep) metallic violet band, bordered below by broader (16–22 mm deep) scarlet band, with brown speckling; dark olive below, pectoral tufts yellow, underwing-coverts and axillaries grey; iris dark brown; bill and legs black. Non-breeding male resembles female, but wings darker and wing-coverts retain metallic coloration. Female is

dark olive-green above, darker on side of face, wings and tail dark brown, wing feathers with pale edges, primaries with yellow tinge on edges, lesser and median coverts dark olive-green; grey-olive with indistinct darker barring below, centre of belly pale, tinged yellow, underwing-coverts and axillaries white, washed yellow; bare parts as male. Juvenile undescribed. Race *chapini* male has shorter bill (22–25 mm) than nominate, darker red breastband, belly dark grey; *graueri* male is similar to nominate but smaller and shorter-billed (17.5–21.5 mm), with uppertail-coverts more violet blue, breastband brick-red, and abdomen buff-grey, less olive; *schubotzi* female has throat and upper breast darker grey than other races. Voice. Warbling song consists of “chee-oo, che che, chee-oo, che che, se, se, se, se, se, se, se, se, ee chit, che chit-che chit”, rising just before end and then dropping. Calls include “tsp”, “chee-chee” and drawn-out “iseeep”.

Habitat. *Hypericum* scrub, montane forest, bamboo, heaths, forest edges and clearings, above 2000 m.

Food and Feeding. Nectar, insects, and spiders (Araneae). Forages singly and in pairs; sometimes in larger flocks. Visits flowers of *Balthasaria schliehii*, *Crotalaria agatiflora*, *Hypericum revolutum*, *Kniphofia princiae*, *Labellia gibberoa*, *Labellia mildbraedii* and *Symphonia globulifera*. Forages also in manner of a tit (Paridae), in trees.

Breeding. Egg-laying in Jun, Sept and Dec in DR Congo and Sept and Dec in Uganda. Male displays involve hopping with drooped and quivering wings while singing, with pectoral tufts played at right angles to body. Nest built by female, small oval structure constructed from *Usnea* lichen, moss, leaves, feathers and pappus, held together with cobwebs, lined with pappus and feathers, placed 2–5 m up in tree. Clutch 1 egg, dark olive with darker olive freckles (nominate race) or matt white and covered with ash-grey or pale brown markings with dark ring at wider end (*graueri*); no information on incubation and nestling periods.

Movements. No information.

Status and Conservation. Not assessed. Restricted-range species; present in Albertine Rift Mountains EBA. Abundant in Burundi near Rwanda border between 2750 m and 3500 m, but rare below 2400 m. Uncommon in Rwenzori Mts in DR Congo. Abundant above 2750 m on Mt Muhavira, in Uganda.

Bibliography. Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Clancey & Irwin (1978), Dowsett-Lemaire (1990), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Gyldestolpe (1924), Mackworth-Praed & Grant (1945), Prigogine (1952, 1979), Schouteden (1938), Williams (1952).

61. Prigogine's Double-collared Sunbird

Cinnyris prigoginei

French: Souimanga de Prigogine **Spanish:** Suimanga de Prigogine
German: Marungunektarvogel
Other common names: Marungu/Prigogine's Sunbird

Taxonomy. *Cinnyris afer prigoginei* Macdonald, 1958, Marungu Highlands, DR Congo.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. stuhlmanni* and *C. ludovicensis*; sometimes treated as conspecific with one or other of those. Has been considered conspecific also with *C. afer*, and is closely related to *C. reichenowi*. Considered by some to be possibly of hybrid origin, perhaps *C. stuhlmanni* × *C. medioeris*. Monotypic.

Distribution. Marungu Highlands, in SE DR Congo.

Descriptive notes. 13 cm; 8–10.9 g. Male breeding has head and mantle iridescent blue-green with golden reflections, rump blue, uppertail-coverts iridescent purple-blue; uppertail black with bluish tinge, tipped white with narrow white edges on two outer feather pairs; remiges and upperwing-coverts black; narrow breastband iridescent purplish-blue (more blue than uppertail-coverts), below which a very narrow (10 mm deep) dark red band; bright yellow pectoral tufts; belly yellow-olive, lower belly and undertail-coverts grey-brown, undertail dark brown, edged whitish; iris dark brown; bill and legs black. Non-

breeding male may have non-metallic olive intermixed with metallic green feathers on crown, side of head and back, with primaries and wing-coverts brown, not black, and lower abdomen greyish. Female has forehead to rump uniformly olive, uppertail black, outer feathers edged white, remiges dark brown or black, outer edges of primaries with olive-green edges and secondaries with edges more yellow-green; chin and throat dark olive with dusky markings, underparts olive, darker on upper breast, with flanks and vent yellow-olive, undertail black, broadly edged white; bill black with pale base, legs black. Juvenile undescribed. Voice. Song a high-pitched warble. Calls various cheeps and ticking notes.

Habitat. Montane forest, thickets and fields near rivers and streams, in montane areas to at least 1900 m.

Food and Feeding. No data; diet presumably nectar and invertebrates.

Breeding. Birds with active gonads in Feb and Apr. No other information.

Movements. No data.

Status and Conservation. Not assessed. Locally common. Deforestation by humans and streambank erosion by cattle pose threats to this species' restricted habitat.

Bibliography. Benson & Prigogine (1981), Chapin (1954), Cheke & Mann (2001), Clancey & Irwin (1978), Collar & Stuart (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Prigogine (1974), Macdonald (1958), Prigogine (1979), Schouteden (1949).

62. Montane Double-collared Sunbird

Cinnyris ludovicensis

French: Souimanga d'Angola **German:** Bergnektarvogel **Spanish:** Suimanga Angoleño
Other common names: Ludwig's Double-collared Sunbird, Boeage's Montane Double-collared Sunbird

Taxonomy. *Nectarinea* [sic] *ludovicensis* Boeage, 1868, Biballa, Mossamedes, Angola.

On following pages: 63. Northern Double-collared Sunbird (*Cinnyris reichenowi*); 64. Greater Double-collared Sunbird (*Cinnyris afer*); 65. Regal Sunbird (*Cinnyris regius*); 66. Rockefeller's Sunbird (*Cinnyris rockefelleri*); 67. Eastern Double-collared Sunbird (*Cinnyris medioeris*); 68. Moreau's Sunbird (*Cinnyris moreaui*); 69. Loveridge's Sunbird (*Cinnyris loveridgei*).

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. stuhlmanni* and *C. prigoginei*; sometimes treated as conspecific with one or other of those. Has been considered conspecific also with *C. afer*, and is closely related to *C. reichenowi*. Races geographically isolated from each other, possibly represent separate species. Further, an as yet undescribed taxon, apparently close to race *whytei*, occurs in NE Zambia and Tanzania (where fairly common at some localities in Eastern Arc mountains at forest edges and towards rainshadow NW of mountains); may belong with this species or *C. manoensis*, or represent a distinct species (see page 201). Two subspecies recognized.

Subspecies and Distribution.

C. l. ludovicensis (Bocage, 1868) – highlands of W Angola.

C. l. whytei Benson, 1948 – N Malawi (Nyika Plateau) and adjacent parts of Zambia.

Descriptive notes. 12–13 cm; 7–11 g. Male nominate race has head, upperparts and chin to breast iridescent green with gold reflections, uppertail-coverts metallic blue with violet sheen; uppertail black glossed blue, with white tips and narrow white edges on two outer feather pairs; lesser and median wing-coverts metallic green, rest of upperwing dark brown, flight-feathers edged olive-brown; green of upper breast divided from broad red lower breastband by narrow (2 mm wide) violet-blue band; pectoral tufts yellow, rest of underparts olive, pale grey underwing; iris dark brown; bill and legs black. Female is dark grey-brown

above, uppertail-coverts darker, tail black-brown, outermost rectrix and distal portion of adjacent one paler brown and with tips of inner webs grey-white, upperwing dark grey-brown, edged olive-brown, primaries thinly edged more golden olive-brown; narrow supercilium pale buff, face grey-brown, lores black-brown; chin grey-buff, throat and upper breast browner, mottled with buff, otherwise brown-grey below, middle of lower breast and belly paler and tinged olive-yellow, underwing and inner borders of underside of remiges grey-white; bare parts as male. Juvenile undescribed. Race *whytei* male has upper breastband more steel blue and wider (3 mm) than nominate and red breastband darker, more scarlet, and narrower, with some dusky bars, female is darker on chin and throat and with duller underparts greener. Voice. Song (race *whytei*) consists of bursts of high notes, “ti, ti, titi pitsy-pitsy, chu-chu-chu pitsy-pitsy, titititipitsy, piehew, chichichichi...”. Calls include variety of ticking notes; alarm call “tchep”.

Habitat. Montane forest, forest edge and grassland.

Food and Feeding. Nectar and insects. Forages singly and in pairs. Visits variety of flowers, including aloes (*Aloe*), mistletoes (*Loranthaceae*), *Canthium guenzii*, *Clerodendrum quadrangulatum*, *Crotalaria goetzei*, *Disa satyriopsis*, *Gladiolus natalensis*, *Halleria lucida*, *Hypericum revolutum*, *Impatiens gomphophylla*, *Lobelia giberroa*, *Pentas schimperana*, *Syzygium cordatum* and *Tecoma capensis*, and species of genera *Kniphofia*, *Leonotis* and *Protea*.

Breeding. Egg-laying in Feb–Aug in Malawi and birds with enlarged gonads Oct–Dec in Angola; two or three broods per season. Nest-building by female, nest suspended 1.5–5 m up in *Hagenia abyssinica*, *Buddleja salviifolia*, *Erica benguelensis*, *Rhus longipes* or *Anthospermum* species; material sometimes reused for subsequent nests; defended territory 0.1–0.5 ha. Clutch 1 egg, size (race *whytei*) 16.5–18.3 × 11.5–13.2 mm, otherwise undescribed; incubation by female, period c. 2 weeks; chicks brooded and fed by female, sometimes fed also by male, no information on duration of nestling period; fledglings fed by female or by both parents. Undescribed form (possibly belonging to present species or *C. manoensis*, or a distinct species) has been found breeding in NE Zambia; nest made of grass; eggs pale and freckled.

Movements. Apparently resident on Nyika Plateau.

Status and Conservation. Not assessed. Restricted-range species: present in Western Angola EBA. Locally common in Angola and Malawi.

Bibliography. Benson (1948), Cheke & Mann (2001), Dowsett (1983), Dowsett-Lemaire (1988, 1989a), Fry *et al.* (2000), Grant & Mackworth-Præd (1943b), Johnson & Brown (2004), Traylor (1962).

63. Northern Double-collared Sunbird

Cinnyris reichenowi

French: Souimanga de Preuss **German:** Preussnektarvogel **Spanish:** Suimanga de Preuss
Other common names: Preuss's/Nandi Double-collared Sunbird

Taxonomy. *Cinnyris reichenowi* Sharpe, 1891, Sotik, south-west Kenya.

Genus often subsumed in *Nectarinia*. With such treatment, specific name of this species becomes preoccupied and is replaced by next available name, *kikuyuensis*; *preussi* then has date priority and becomes the nominate race. May form a superspecies with *C. afer*. Proposed races *genderuensis* (from Genduru Mts, in Adamaoua Plateau, in NC Cameroon) and *parvirostris* (from Bioko I) considered inseparable from *preussi*. Two subspecies recognized.

Subspecies and Distribution.

C. r. preussi Reichenow, 1892 – Bioko I (Fernando Pó), SE Nigeria, Cameroon and NW Central African Republic.

C. r. reichenowi Sharpe, 1891 – S Sudan, NE DR Congo, SW, NE & E Uganda, Rwanda, Burundi and W & C Kenya.

Descriptive notes. 11–12 cm; 5–10 g. Male nominate race has head, mantle, back, cheek and throat metallic green with steel-blue gloss, rump grey-brown with olive feather tips, uppertail-coverts metallic purple; tail black, glossed blue; upperwing and greater wing-coverts dark brown, lesser wing-coverts metallic green; thin purple band on lower throat, above scarlet breast; pectoral tufts yellow, rest of underparts dark olive-brown, somewhat paler on lowermost areas; underwing brown; iris black or dark brown; bill and legs black. Female is dull brownish olive-green above and on cheek, with remiges edged olive-yellow, tail very dark

brown; chin and throat greyer, latter strongly washed with olive, rest of underparts paler olive than upperparts, with yellow wash on belly, axillaries pale yellow, underwing-coverts white; iris dark brown, bill and legs black. Immature male resembles female. Race *preussi* is very like nominate, but has longer bill (16–19 mm; nominate 14–15 mm) and abdomen browner, less olive. Voice. Song of race *preussi* a burst of “chup-chup-ch-ch-ch” or “tsup-tsup” preceding a run of warbles, inter-

persed with up to c. 10 “psee” notes; song of nominate has a 2-note start before a fast twitter and then “tsip...tsweet...susususrisrisri-tsew-tsutsu-tsu”. Calls various high-pitched “zeet” or “chip”. **Habitat.** Montane heathland in Cameroon and on Bioko, and sometimes down to sea-level; montane, secondary and gallery forest, forest edge, plantations and gardens in E Africa. Reaches 2450 m in Rwanda, and above 1800 m in Sudan.

Food and Feeding. Insects, spiders (*Araneae*) and nectar. Forages singly and in pairs, outside breeding season also in groups; sometimes in mixed-species flocks. Nectar taken from *Erythrina* species, forest trees, aloes (*Aloe*), mistletoes (*Loranthaceae*), herbaceous plants, thistles and creepers. Nectar-robs from *Hibiscus*.

Breeding. Egg-laying recorded in Nov in Nigeria and Aug–Feb in Cameroon, May and Nov in DR Congo, Nov and Jan–Feb in Rwanda, Jan and Aug–Sept in Uganda and Jul in Kenya. Nest built by female alone, domed, with short porch, constructed from grass, moss, lichens and fibres, held together with cobwebs, lined with feathers, suspended 2–15 m above ground and well hidden in moss-covered branches of forest trees. Clutch 1–2 eggs, mauve-grey and pink-grey, heavily speckled black-brown or brown or grey, with grey blotches and blackish stripes. No other information.

Movements. Altitudinal migrant in Cameroon, appearing below breeding range during rainy season in Jul–Sept. Similar pattern in E Africa; common on Mt Elgon (Kenya) at 2800 m in Dec, but absent there in Jul.

Status and Conservation. Not globally threatened. Common on Bioko, and common to locally abundant in Cameroon and Nigeria; common to very common also in S Sudan, DR Congo and Burundi, and locally common elsewhere in E range.

Bibliography. Bannerman (1948, 1951), Bates (1927), Bennun (1986), Borrow & Demeu (2001), Boulton & Rand (1952), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire (1990), Eisenraut (1963), Eyckerman & Cuvelier (1982), Friedmann (1937), Fry *et al.* (2000), Grimes (1971), Hall & Moreau (1970), Lewis & Pomeroy (1989), Louette (1980), Newsome (1986), Nikolaus (1987), Serle (1951, 1957), Zimmerman *et al.* (1996).

64. Greater Double-collared Sunbird

Cinnyris afer

French: Souimanga à plastron rouge **Spanish:** Suimanga Bicollar
German: Doppelband-Nektarvogel

Other common names: Larger Double-collared/Red-breasted Sunbird

Taxonomy. *Certhia afra* Linnaeus, 1766, Cape of Good Hope, South Africa.

Genus often subsumed in *Nectarinia*. May form a superspecies with *C. reichenowi*; has sometimes been considered conspecific with *C. stuhlmanni*, *C. prigoginei* and *C. ludovicensis*. In addition, an undescribed taxon apparently close to present species, but probably closer to *C. ludovicensis* (of race *whytei*) or to *C. manoensis*, has recently been discovered in Eastern Arc mountains of Tanzania and in NE Zambia (see page 201). Races intergrade in SW Eastern Cape. Race *saliens* regarded by some authors as being of dubious validity. Two subspecies currently recognized.

Subspecies and Distribution.

C. a. afer (Linnaeus, 1766) – S South Africa (S Western Cape and SW Eastern Cape).

C. a. saliens (Clancey, 1962) – E South Africa (Limpopo Province and NE Gauteng S to NW KwaZulu-Natal and S Eastern Cape), W Swaziland and E Lesotho.

Descriptive notes. 11.5–12.5 cm; male 9–18 g, female 8.1–14 g. Male nominate race has head to rump metallic green with blue iridescence (but bases of feathers brown), uppertail-coverts iridescent violet, tail brown-black thinly glossed blue, with narrow whitish edges to outermost feather pair, flight-feathers, primary coverts and greater wing-coverts brown, median and lesser wing-coverts metallic green; throat metallic green, narrow blue-violet band above scarlet breast and upper belly, otherwise dark olive-buff below; iris dark hazel; bill and legs black. Female is smaller and shorter-billed than male, has head and upperparts dark

olivaceous grey, tail brown-black with slight blue gloss, outermost feather pair distally pale brown, wing grey-brown, flight-feathers, primary coverts and greater wing-coverts edged buffish; throat and breast grey, speckled with grey-olive, greyish-buff sometimes with yellow tinge below, paler on belly, flanks and undertail-coverts, axillaries and underwing-coverts pale green. Juvenile resembles female. Race *saliens* male is larger than nominate, has lighter non-metallic underparts, lighter red breastband with rest more yellow, female paler and greyish, more heavily patterned on throat and breast and greener on middle of lower underparts. Voice. Song, by both sexes, a melodious twitter involving “weetu” whistles, alternating between loud and soft, between series of 20 or more “tsi” notes, this followed by 3 or 4 “tsk” notes or fast repetitions of “weet” or “tscheep” (five times per second for 30 seconds). Varied calls include “sskert”, “tsig-tsig”, “chay-ing-chay-ing”, also “ch, ch, ch, cher-rrreee” and “issweeee”.

Habitat. Open habitats with scrub, from coastal plains to Afriomontane forest edge, including succulent karoo, *Protea* savanna, fynbos, moist woodland, parks and gardens.

Food and Feeding. Insects, including beetles (*Coleoptera*), flies (*Diptera*), homopteran bugs, Hymenoptera and Lepidoptera; also spiders (*Araneae*); also nectar and plant juices. Forages singly, in pairs and in small groups; joins mixed-species flocks. Takes spiders from their webs; seizes insects on the wing in sallies and by hovering. Gleans flowers and leaves for arthropods. Probes flowers for insects and nectar; takes juices of figs and grapes, and partial to liquid exudate at exit holes of fig-wasp *Elisabethiella baijnathi* in the fig *Ficus burtt-daveyi*. Visits *Acacia sieberiana*, aloes (*Aloe*), *Ananas comosus*, *Burchellia buhalisia*, *Crotalaria agatifolia*, *Disa chrysostachya*, *Hypericum revolutum*, *Kniphofia princiae*, *Lobelia giberroa*, *Lobelia mlsbraedii*, *Plumbago auriculata*, *Protea caffra*, *Protea roupelliae*, *Pyrostegia venusta*, *Spermacoce dibrachiata*, *Strelitzia reginae*, *Symphonia globulifera*, various figs (including *Ficus burtt-daveyi*), and species in the genera *Balthasaria*, *Bauhinia*, *Canna*, *Cotyledon*, *Erica*, *Erythrina*, *Gasteria*, *Hibiscus*, *Schotia*, *Tecoma* and *Vitis*.

Breeding. Egg-laying in all months in South Africa; up to three broods. Male sings with head pointing skywards in close proximity to rivals, which respond with head-bobbing; cloaca-pecking common. Displaying male sways left and right, bobs head, fans tail and shows pectoral tufts, also indulges in jerky display-flights; partners may swing upside-down from perches. Nest built by female, taking 10–24 days, oval, with side entrance near top, porch of grass extending 3.5–6 cm out, construction variable, some neat and others messy, materials include grass, bark, twigs, roots, leaves, lichen, string, rags, small fruits, leaf mould, feathers, wool or fur, held together with cobwebs, decorated with leaves, old snakeskin, lichen and even cloth, lined with feathers and wool, placed 1.5–7 m up in tree or shrub. Clutch 1–2 eggs, white, grey or green-white, heavily marked

with light slate-grey or olive or brown speckles, streaks, lines and spots; incubation by female, period 15 days; chicks fed by both parents, nestling period 2 weeks; both also feed fledglings for c. 10 days after latter leave nest. Nests parasitized by Klaas's Cuckoo (*Chrysococcyx klaas*).

Movements. Moves, including altitudinally, in response to flowering of plant sources.

Status and Conservation. Not globally threatened. Common or locally common in South Africa. **Bibliography.** Benson & Prigogine (1981), Brieschke (1991), Cheke & Mann (2001), Clancey (1962, 1970c), Clancey & Irwin (1978), David & Gosselin (2002b), Fry *et al.* (2000), Hall & Moreau (1970), Harebottle (1999), Harrison (1997a), Hockey *et al.* (2005), Hutton (1985), Johnson & Brown (2004), Keast (1968d), Lloyd (1989, 1991), Lloyd & Craig (1989), Macdonald (1985), Milstein (1963), Oatley & Best (1997), Schoeman (1990), Skead (1954, 1967), de Swardt (1991a), de Swardt & Schoeman (1997).

65. Regal Sunbird

Cinnyris regius

French: Souimanga royal

German: Königsnektarvogel

Spanish: Suimanga Real

Taxonomy. *Cinnyris regia* [sic] Reichenow, 1893, Central Africa = Rwenzori, DR Congo. Genus often subsumed in *Nectarinia*. Probably closely related to *C. rockefelleri*. Proposed race *kivuensis* (from Kivu Volcanoes, in DR Congo) considered indistinguishable from nominate. Two subspecies recognized.

Subspecies and Distribution.

C. r. regius Reichenow, 1893 – E DR Congo, SW Uganda, W Rwanda and W Burundi.

C. r. anderseni J. G. Williams, 1950 – W Tanzania.

Descriptive notes. 10–11 cm; 5–8 g. Male nominate race is iridescent emerald-green from head to rump, including scapulars and median and lesser upperwing-coverts, and from chin to upper breast; uppertail-coverts violet; tail graduated, central rectrices protrude 3 mm beyond rest, dark brown with violet sheen, outer rectrices paler than others; remiges dark brown, edged olive-green; narrow violet upper breastband above scarlet centre of lower breast and belly, bright yellow on side of breast and flanks, olive-green thighs and vent, red undertail-coverts; underwing-coverts off-white with yellow wash, axillaries dull olive, under-

side of remiges grey; iris dark brown; bill and legs black. Female is dark olive-green above, remiges dark brown, secondaries with outer webs elongated and brown-olive, lesser and median wing-coverts olive, tail dark brown with violet sheen, outermost feathers paler; chin and throat dusky white, lightly streaked yellow, breast darker, otherwise yellow-green below, underwing-coverts white, tinged yellow, axillaries pale green, inner webs of undersides of remiges fringed pale grey; bare parts as male. Juvenile resembles female, but juvenile male has iridescent green throat patch and shoulder patches, red patches on chest, belly and base of undertail-coverts, pale yellow belly; immature male as adult male, except that upperparts, face and neck to chest as adult female but with a few metallic-coloured feathers. Race *anderseni* differs from nominate in having bill broader at base, male has red below altering posteriorly to orange, with abdomen duller olive-yellow; flanks more olive, undertail-coverts chrome-orange (not red), female has upperparts washed grey. Voice. Song consists of repetitions of rapid twitter of rising and falling notes, followed by "tsi". Calls include "djer", "dzit", "dit" and "tchic-tchic".

Habitat. Montane forest, clearings, bamboo and scrub, at 1500–3100 m.

Food and Feeding. Insects and nectar. Forages singly and in pairs. Seeks food from plants such as mistletoes (Loranthaceae), *Englerina woodfordioides*, *Lobelia giberroa*, *Oxyanthus troupinii*, *Symphonia gabonensis*, *Symphonia globulifera*, *Triumfetta cordifolia* and species in genera *Albizia*, *Canthium*, *Impatiens*, *Ipomoea*, *Pavetta*, *Sericostachys*, *Syzgium* and *Virecacia*.

Breeding. Egg-laying Apr–May in DR Congo and Apr–Jun and Oct in Uganda. Oval nest made of fibres and moss, lined with plant down and feathers, suspended 4–5 m up in bamboo, fern or other available plant. Clutch 1 egg, grey, grey-brown at wider end, where dark grey speckles concentrated. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Restricted-range species: present in Albertine Rift Mountains EBA. Common or locally common.

Bibliography. Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Dowsett-Lemaire (1990), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Hall & Moreau (1970), Kunkel (1966), Prigogine (1971), Schouteden (1938), Williams (1950a).

66. Rockefeller's Sunbird

Cinnyris rockefelleri

French: Souimanga de Rockefeller

Spanish: Suimanga de Rockefeller

German: Blutbrust-Nektarvogel

Taxonomy. *Cinnyris rockefelleri* Chapin, 1932, Mount Kandashomwa, eastern DR Congo.

Genus often subsumed in *Nectarinia*. Probably closely related to *C. regius*. Monotypic.

Distribution. Mountains of E DR Congo.

Descriptive notes. 12 cm; 5–5.5 g. Male has head to rump, including scapulars, bright metallic green with golden tinge, uppertail-coverts glossy violet-blue, tail blue-black; remiges black-brown, outer portions of outer webs edged olive-green, as are lesser and median wing-coverts, secondaries have unusually long outer webs (conspicuous even when wing folded); chin to upper breast metallic green, bordered below by narrow (4 mm) violet band, upper belly bright scarlet, bordered by yellow (sometimes belly brighter scarlet than lower breast, as some yellow feathers intermixed), pectoral tufts bright yellow; lower belly, flanks

and thighs dark olive-green with some brighter olive-green streaks, undertail-coverts scarlet; underwing-coverts dull white, some tipped olive, undersides of remiges with white borders on

outer edges of inner webs; iris brown; bill and legs black. Female has dark olive and black forehead and crown (appearing mottled), conspicuous pale olive supercilium reaching 3 mm behind eye, black lores and thin eyestripe, pale yellow-olive ear-coverts; upperparts dark olive-green, rounded tail dark brown, central feather pair tinged dark blue and 3 mm longer than outermost rectrix, remiges dark brown, broadly edged yellow-green, outer webs of secondaries elongated as in male; chin and throat yellowish-green, chest and breast darker, lower belly and undertail-coverts bright olive-green with creamy yellow tinge (but duller than chin and throat), underwing-coverts white with yellowish edges (visible on folded wing), underside of remiges grey-brown, inner webs edged white; bare parts as male. Juvenile undescribed. Voice. Song apparently undescribed. Contact calls reported as harsh "schick schick".

Habitat. Highland valleys and streams in tall bamboo and heath (Ericaceae) zones, including arborescent heather at 2050–3300 m.

Food and Feeding. Few data. Diet insects and, presumably, nectar. Forages singly and in pairs; occasionally joins mixed-species flocks.

Breeding. Birds with enlarged gonads in May and in primary moult in Jul. No other information.

Movements. No data.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in Albertine Rift Mountains EBA. Poorly known. Thought to have very small population, estimated at merely 250–999 individuals, which is considered stable. Occurs in N Itombwe Mts and mountains to N & W of L Kivu, in E DR Congo; single unconfirmed records from Rwegura, in Burundi, and Nyungwe, in Rwanda. Maximum potential area of distribution estimated as 9800 km². Parts of restricted range probably threatened by deforestation. Some protection afforded by the Kahuzi-Biéga National Park, W of L Kivu, but illegal activities known to take place there at times (e.g. armed militias carried out illegal hunting, logging and mining in 2001). Protection of Itombwe Mts should be sought as a priority.

Bibliography. Anon. (2007f), Butchart & Stattersfield (2004), Chapin (1954), Cheke & Mann (2001), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett-Lemaire (1990), Fry *et al.* (2000), Gaugris (1976), Gaugris *et al.* (1981), Hall & Moreau (1970), Hendrickx & Massart-Lis (1952), Prigogine (1971), Stattersfield & Capper (2000).

67. Eastern Double-collared Sunbird

Cinnyris mediocris

French: Souimanga du Kilimanjaro

Spanish: Suimanga del Kilimanjaro

German: Füllebornnektarvogel

Other common names: Usambara Double-collared Sunbird (*usambaricus*); Forest Double-collared Sunbird (*fuelleborni*)

Taxonomy. *Cinnyris mediocris* Shelley, 1885, Kilimanjaro, Tanzania.

Genus often subsumed in *Nectarinia*. May form a superspecies with *C. moreaui* and *C. loveridgei*. Recent analyses of mitochondrial DNA suggest that nominate race, *usambaricus*, and *fuelleborni* may represent three distinct species, but status of *bensoni* obscure. Four subspecies recognized.

Subspecies and Distribution.

C. m. mediocris Shelley, 1885 – W & C Kenya and N Tanzania.

C. m. usambaricus Grote, 1922 – SE Kenya and NE Tanzania.

C. m. fueleborni Reichenow, 1899 – C & S Tanzania, NE Zambia (Mafinga Mts) and N Malawi (Karonga District).

C. m. bensoni J. G. Williams, 1953 – S Malawi and N Mozambique.

Descriptive notes. 11–12 cm; 5.2–10.7 g. Male nominate race has head and neck, upperparts, including lesser and median wing-coverts, and chin to breast iridescent golden-green, tinged blue near tips of feathers, lores black, uppertail-coverts metallic methyl-blue; tail very dark blackish-brown and glossy, slightly graduated, outermost feather and distal half of adjacent one paler and tipped white on inner webs, outermost also on outer web; upperwing dark greyish-brown, remiges and greater wing-coverts with olive-yellow edges; thin band of methyl-blue on uppermost breast, broad scarlet (grenadine-red) breastband (10–13 mm deep),

lemon-yellow pectoral tufts (11–21 mm long), belly and vent light olive-yellow; underwing-coverts off-white, axillaries pale greenish; iris dark brown or black; bill and legs black. Female is dark olive-green above, lores darker, tail glossy grey-brown, slightly graduated, outer two feathers tipped brown-white on inner webs and outermost also on outer web, remiges dark brown, edged olive-green, median and lesser wing-coverts dark olive; chin and throat olivaceous green with yellow speckling, underparts olive-yellow, darker on breast and flanks, underwing-coverts white with yellow wash, axillaries olivaceous yellow; bare parts as male. Juvenile resembles adult female, but darker below. Race *usambaricus* male has uppertail-coverts violet or royal-blue (instead of methyl-blue), grenadine-red breastband narrower (6–8 mm) than nominate and with grey-brown wash below it, belly more yellowish than in other races and washed grey, female greener, with deeper olive throat; *fuelleborni* male has uppertail-coverts grey or metallic green proximally, tipped violet or purplish (instead of blue), scarlet to orange-red breastband broader (11–20 mm deep) than those of nominate and previous and often with yellow at sides, differs further in having olive-green belly to vent without yellow (but sometimes with brown tinge) and undertail-coverts sometimes scarlet-tipped, scarlet-washed or all scarlet, female darker than nominate and previous; *bensoni* male differs from nominate in having uppertail-coverts violet, rather than blue, and breastband darker red, from all other races in dusky (sooty) olive-green belly and vent lacking any trace of yellow, female indistinguishable from last but darker than nominate. Voice. Song consists of "tseep", a 0.5-second gap, another "tseep" and then a descending "ts-szurr" followed by a warble, e.g. "peety-jateece-jatece-jatece-tsrrt-tsrrt-ja-peety-peety-peety-ja", likened to sound made by shaking a metal chain. Calls include "chek chek" and "tse", also fast series of "tchep tchep tchep tchep" as alarm.

Habitat. Upland areas such as montane forests, bamboo stands, heathland, open grassy areas and gardens.

Food and Feeding. Nectar; also insects, including flies (Diptera), Hymenoptera and Neuroptera, also spiders (Araneae) and small molluscs. Nectar taken from wide range of plants, including *Acaia abyssinica*, *Bridelia brideliifolia*, *Canthium guenzii*, *Carduus kinensis*, *Crotalaria goetzei*, *Dombeya goetzei*, *Echinops amplexicaulis*, *Erica arborea*, *Faurea saligna*, *Hagenia abyssinica*, *Halleria lucida*, *Hoslundia opposita*, *Protea kilimandscharica*, species in the genera *Clematis*, *Englerina*, *Erythrina*, *Hypericum*, *Impatiens*, *Kniphofia*, *Leonotis* and *Lobelia*; also visits *Usnea* lichen, presumably in search of invertebrates. Forages singly and in pairs; joins mixed-species parties. Forages on leaves, nectar-robs plants, and catches flying ants in flight.

Breeding. Egg-laying recorded in Jul and Dec in Kenya, Jun, Aug and Oct–Jan in Tanzania, and Apr–Oct in Malawi. Male displays pectoral tufts to other males while courting female. Male assists in building nest, a domed pouch made of *Usnea* lichen and grass strands, lined with down and feathers, suspended 2–2.5 m above ground; same territory of c. 0.2 ha of forest maintained by pair year after year. Clutch 1–2 eggs, pale green-white with indistinct grey-brown marks; no information on incubation and nestling periods.

Movements. Descends to lower altitudes after breeding.

Status and Conservation. Not globally threatened. Common throughout range.

Bibliography. Baker & Baker (2007), Benson & Benson (1977), Bowie *et al.* (2004a), Cheke (1971a, 1971b, 1972), Cheke & Mann (2001), Dowsett (1983), Dowsett & Dowsett-Lemaire (1984), Dowsett-Lemaire (1988, 1989a, 1989b), Friedmann (1937), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Hall & Moreau (1970), McCarthy (2006), Selater & Moreau (1933), Stuart & van der Willigen (1980), Williams, A.A.E. (1978), Williams, J.G. (1950b, 1953c), Zimmerman *et al.* (1996).

68. Moreau's Sunbird

Cinnyris moreau

French: Souimanga de Moreau **German:** Moreaunektarvogel **Spanish:** Suimanga de Moreau

Taxonomy. *Cinnyris mediocris moreau* W. L. Selater, 1933, Maskati, Nguru Range, Tanzania. Genus often subsumed in *Nectarinia*. May form a superspecies with *C. mediocris* and *C. loveridgei*; former suspicion that this species may be a hybrid between those two is not borne out by recent DNA analyses, which strongly indicate its validity as a full species and suggest that it is sister to *C. loveridgei*. Monotypic.

Distribution. Mountains of E Tanzania.

Descriptive notes. 11–12 cm; 5.1–10.4 g. Male has head to lower back, including scapulars and lesser and median wing-coverts, and chin to breast iridescent bronzy green, rump non-metallic olive-green, uppertail-coverts glossy purplish-violet at tip; slightly graduated tail dark brown, faintly glossed, with paler outer feathers, upperwing very dark brown, edged olive-yellow; narrow band (2 mm deep) of glossy blue on chest, above red to orange patch (10–15 mm deep) on middle of lower breast bordered by yellow on side of breast, strontium-yellow pectoral tufts not well defined (as yellow feathering continued on each side of scarlet breast

patch); belly to vent dark olive-yellow, underwing-coverts and axillaries pale greenish-yellow; iris dark brown or black; bill and legs black. Female is olive-green above, with metallic green-grey edges on crown and mantle, tail very dark brown with paler outer feathers, narrow olive-yellow edges to rectrices in fresh plumage, remiges and greater wing-coverts very dark brown, edged olive-ochre, breast and abdomen bright olive-yellow, chin and throat greyer, underwing-coverts and axillaries pale green-yellow; iris dark brown, bill and legs black. Juvenile male has head to uppertail-coverts dusky grey-olive, is dusky yellow-olive below, brighter and more yellow on lower breast and middle of abdomen, which is duskier and less yellow than adult; immature female resembles adult but duller below. **Voice.** Song a fast outburst of high-pitched notes. Calls consist of regularly spaced chirps.

Habitat. Areas with moist montane forest and clearings in mountainous regions; mainly at 1300–1850 m, but to 2500 m in Udzungwa Mts.

Food and Feeding. Few data available. Expected to take nectar and insects, but to date only foodplant known is *Achyroperum carvalhii*. Forages, sometimes in mixed-species groups, in canopy or in bushes.

Breeding. Egg-laying in Dec, and other breeding activity recorded in Aug–Oct. Small domed purse-shaped nest, built by female, of leaves or grass, suspended 1–10 m up in shrub or tree. Clutch assumed to be of 1–2 eggs (nest with two chicks, and two fledglings together in Aug–Sept); eggs whitish with grey-brown marks. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Tanzania–Malawi Mountains EBA. Has small range in Nguru, Nguu, Uvidunda, Ukaguru and Udzungwa Mts; common or abundant in suitable areas, e.g. in Nguu Mts and Ukagurus. Appears to be forest-dependent, and therefore presumably sensitive to destruction or degradation of forest habitat. Occurs in Udzungwa Mountains National Park and, in Ukagurus, Mamiwa Kisara Forest Reserve.

Bibliography. Anon. (2007), Baker & Baker (2007), Bowie *et al.* (2004a), Butchart & Stattersfield (2004), Cheke & Mann (2001), Dinesen *et al.* (2001), Evans & Anderson (1993a, 1993b), Ejlsdals *et al.* (1997), Fry *et al.* (2000), Fuggles-Coeleman (1986), Hall & Moreau (1970), Jensen & Brogger-Jensen (1992), McCarthy (2006), Selater & Moreau (1933), Seddon *et al.* (1999a, 1999b), Stattersfield & Capper (2000), Stuart & van der Willigen (1980), Williams (1950b, 1950c).

69. Loveridge's Sunbird

Cinnyris loveridgei

French: Souimanga de Loveridge

Spanish: Suimanga de Loveridge

German: Orangebauch-Nektarvogel

Taxonomy. *Cinnyris loveridgei* E. J. O. Hartert, 1922, Uluguru Mountains, east Tanzania. Genus often subsumed in *Nectarinia*. May form a superspecies with *C. mediocris* and *C. moreau*; recent DNA analyses suggest that present species is sister to latter. Monotypic.

Distribution. Uluguru Mts, in E Tanzania.

Descriptive notes. 12 cm; male 9–12.5 g, female 7.5–11 g. Male has head to breast and upperparts, including scapulars and lesser and median wing-coverts, iridescent green, apart from non-metallic olive-green rump and purple-violet terminal uppertail-coverts; graduated tail very dark brown, slightly glossy above; upperwing very dark, almost black, secondaries, tertials and primary coverts edged golden-olive (forming wing patch on folded wing); narrow (3 mm) band of metallic violet on upper breast, above orange-ochre breast patch that merges with warm aniline-yellow on side of breast and abdomen, latter tinged olive with

faint orange wash in middle; pectoral tufts not sharply defined (olive-yellow feathering continues onto side of breast); underwing-coverts pale grey-olive, axillaries yellow; iris brown; bill and legs black. Female has crown and side of face olive-grey, contrasting with olive-green upperparts, mantle feathers having green-grey or blue-grey metallic edges, tail very dark brown with paler outer feathers; upperwing dark grey-brown, primaries edged paler brown, secondaries and tertials edged yellowish, primary and greater wing-coverts dark greyish-brown, edged olive-green, median and lesser wing-coverts dark olive-green; chin pale olive-grey, throat dark olive-green, breast and abdomen olive-yellow, underwing-coverts and axillaries white with yellow wash; bare parts as male. Juvenile resembles female, young male distinguishable by pale grey throat and upper breast, remainder of underparts pale grey-green, crown grey, nape and upperparts green-grey. **VOICE.** Song, throughout day (from 25 minutes before sunrise, peak 15 minutes before sunrise and during hour before dusk), a very fast but short (3–4 seconds) warble of high-pitched “tsi” notes, uttered in such quick succession as to be reminiscent of sound made by an insect; these sequences may be initiated by “tsp-tee, tsp-tee”. Calls metallic “tsk” or “pzit”.

Habitat. Montane forest, clearings, plantations with a few trees and shrubs, and more open areas with bamboo, at 1200–2580 m.

Food and Feeding. Nectar; also insects, including caterpillars, flies (Diptera), beetles (Coleoptera) and mayflies (Ephemeroptera); also spiders (Araneae). Seen at flowers of a pea crop, an *Albizia*-like tree, *Lusitanthus cereiflorus* and *Impatiens ulugurensis*. Forages singly and in pairs, also in mixed-species flocks. Insect-catching methods include sallying.

Breeding. Egg-laying in Aug–Mar, and other breeding activity recorded in Apr and Aug. Territorial. Nest a bulky oval, with large side entrance 30–50 mm in diameter at top, no porch, made of grass and moss held together with cobwebs, lined with moss, fine grass or plant down, suspended from bush or tree at mean height of 3–1 m above ground in understorey. Clutch 1–3 eggs, shiny dark olive-green with irregular dark mottling; incubation and most parental duties by female alone; no information on duration of incubation and nestling periods.

Movements. No data.

Status and Conservation. ENDANGERED. Restricted-range species: present in Tanzania–Malawi Mountains EBA. Global population probably c. 37,000 individuals, and confined entirely within three forest reserves covering total of c. 260 km². Threatened by habitat destruction. Field research required in order to determine extent to which this species is capable of tolerating further degradation of its habitat.

Bibliography. Anon. (2007), Baker & Baker (2007), Bowie *et al.* (2004a), Cheke & Mann (2001), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Hall & Moreau (1970), McCarthy (2006), Stuart & van der Willigen (1980), Svendsen *et al.* (1995), Tottrup & Larsen (2005), Tottrup *et al.* (2004), Williams (1950b, 1950c, 1951a).

PLATE 15

70. Beautiful Sunbird

Cinnyris pulchellus

French: Souimanga à longue queue **German:** Elfennektarvogel **Spanish:** Suimanga Colilargo
Other common names: Beautiful Long-tailed Sunbird

Taxonomy. *Certhia pulchella* Linnaeus, 1766, Senegal.

Genus often subsumed in *Nectarinia*. It has been suggested that this species and *C. nectarinioides* link the “*C. mariquensis* complex” with the “*C. chalybeus* complex”. Proposed races *aeger* (described from Aïr, in Niger) and *lucidipectus* (from Wad Medani, on Blue Nile in EC Sudan) considered inseparable from nominate. Two subspecies recognized.

Subspecies and Distribution.

C. p. pulchellus (Linnaeus, 1766) – Mauritania, Senegal and Guinea-Bissau E to Sudan, Eritrea and W Ethiopia, S to Sierra Leone, C Nigeria, N Cameroon, Central African Republic, NE DR Congo, Uganda and NW Kenya.

C. p. melanogastrus (G. A. Fischer & Reichenow, 1884) – W, C & S Kenya and Tanzania.

Descriptive notes. Male 14–17 cm, 5.6–10.2 g; female 9–11 cm, 5.6–8 g. Male nominate race breeding has head, upperparts and upperside-coverts bright metallic green, uppertail-coverts tipped bright metallic green, this merging to blue near dark brown bases; tail blue-black, inner rectrices narrowly fringed metallic green, central rectrices fringed broadly with metallic green at base but narrowly along elongated section (which projects 55–65 mm); remiges dark brown; chin to upper breast metallic green with golden reflections, lower border with narrow metallic blue band; scarlet patch in centre of breast,

yellow feather tips at side of breast, abdomen bright metallic green, undertail-coverts more metallic blue, thighs blackish-brown, vent, axillaries and underwing-coverts black; iris black or dark brown; bill and legs black. Male non-breeding (eclipse plumage; sometimes omitted in equatorial regions) is similar to female, grey-brown above and dull yellow below, but wing and tail feathers black, elongated rectrices sometimes (not always) retained, metallic green feathers on chin, throat, wing-coverts and a few on rump and uppertail-coverts retained (sometimes those on chin and throat lost, leaving pale throat patch). Female lacks iridescence, has crown to rump yellow-tinged dull brown, darker brown on ear-coverts, wing-coverts and tail-coverts, narrow white or pale yellow supercilium behind eye, black-brown tail slightly glossed bronze-green or bluish, rectrices narrowly tipped white, outer pair more broadly so and with white on edge of outer web, remiges and greater wing-coverts dark brown, all with pale olive edges, other wing-coverts, alula and tertials edged pale brown; chin and throat whitish, underparts yellow-tinged, with variable indistinct blackish-brown mottling on breast and flanks, white undertail-coverts, axillaries and underwing-coverts tinged yellow; bare parts as male. Juvenile male as female, but with vertical black streak on throat and upper chest flanked by cream moustachial stripes, and duller below; immature female as adult, but occasionally with brighter yellow underparts, and lacks black throat of immature male. Race *melanogastrus* has longer bill (20–22 mm) than nominate (14–19 mm), and male has black abdomen, red breast patch tends to be wider, undertail-coverts with metallic green-blue tips, and central tail feathers protrude less, female has more dusky streaking below. **VOICE.** Song consists of a warble of rising and falling high-pitched notes, involving “ti-tsu-tswée” and similar variants, lasting for nearly one minute, sometimes including rising series of 3–4 “tsi” notes, or sometimes intermixed with many fast repeats of “che” and a few bursts of “chip-chip”. Calls consist of “chip-chip” or similar sounds, repeated.

Habitat. Dry thorn savannas, riversides and gardens; also in mangrove scrub and along beaches at coast.

Food and Feeding. Nectar and small flowers (e.g. of *Acacia*); insects, and spiders (Araneae). Forages singly, occasionally in small groups. Visits flowers of genera *Acacia*, *Albizia*, *Aloe*, *Bauhinia*, *Bombax*, *Bougainvillea*, *Calotropis*, *Canna*, *Combretum*, *Commiphora*, *Delonix*, *Gmelina*, *Hibiscus*, *Ipomoea*, *Jacaranda*, *Lantana*, *Manihot*, *Moringa* and mistletoes (Loranthaceae); observed also at *Carica papaya* and *Leptadenia heterophylla*. Invertebrates sometimes taken from windows or eaves of houses.

Breeding. Breeds during rainy seasons; laying recorded in Jun–Oct in Mauritania and Senegal, Jun–Mar in Gambia, Jul in Mali, Jun in Burkina Faso, Jul–Sept in Ghana, Jun–Jul in Niger, Feb and Jun–Oct in Nigeria, Jul–Aug in Chad, Jul in Eritrea, Mar and Jun–Oct in Sudan, Feb–Mar, May–Jun and Aug–Oct in Uganda, May–Jul in Kenya, and Dec–Jul in Tanzania. Polygamy suspected, as male may court two females simultaneously. Male displays to female by spreading wings and tail. Territorial; males display to each other from treetops, showing colours of underparts in upright pose, flick wings, and jerk fanned tail from side to side. Nest purse-shaped, with central entrance, most without both porch and “beard” but either may be present occasionally; made variously of fibres, bark, twigs, grass, leaves, cobwebs, vegetable down, plant stems, feathers, lichen and snakeskin, lined with feathers or vegetable down, suspended 1–6 m above ground from tree. Clutch 1–2 eggs, slightly glossy, variously green, blue-grey, brown or grey-white with violet-grey spots, purple-black S-shaped marks, brown or ash streaks and blotches; incubation of eggs and brooding of chicks by female alone; no other information.

Movements. Some resident throughout range, except in far N. Complex movement patterns apparently related to flowering of mistletoes. Populations in S parts of W Africa travel N to breed Feb–Apr, returning S in Sept–Oct; in N part of range, some populations present in dry season migrate S at start of rains, breeding S of dry-season quarters.

Status and Conservation. Not globally threatened. Common throughout most of range. Occurs in many protected areas, examples being Comoe National Park, in Ivory Coast, Waza National Park, in Cameroon, Awash National Park, in Ethiopia, Murchison Falls National Park, in Uganda, and Serengeti and Arusha National Parks, in Tanzania.

Bibliography. Baker & Baker (2007), Bannerman (1948), Borrow & Demey (2001), Carroll (1988), Chapin (1954), Cheke & Mann (2001), Friedmann (1937), Fry (1970), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Hall & Moreau (1970), Koenig (1956), Lewis & Pomeroy (1989), Mundy & Cook (1972), Newby (1980), Nikolaus (1987), Pettet (1977), Serle (1943a), Thonnerieux *et al.* (1989), Zimmerman *et al.* (1996).

71. Mariqua Sunbird

Cinnyris mariquensis

French: Souimanga de Mariqua **German:** Bindennektarvogel **Spanish:** Suimanga del Marico
Other common names: Marico/Southern Bifasciated Sunbird; Western Bifasciated Sunbird (*mariquensis*); Swahili Sunbird (*osiris*)

Taxonomy. *Cinnyris mariquensis* A. Smith, 1836, north of Kurrichaine [= Marico District], North West Province, South Africa.

Genus often subsumed in *Nectarinia*. May form a superspecies with *C. shelleyi*, and both sometimes included in a larger superspecies with *C. congensis*, *C. erythrocerus* and *C. nectarinioides*. Proposed races *ovamboensis* (described from Ovamboland, in NC Namibia) and *lucens* (Pongola Town, in N KwaZulu-Natal, NE South Africa) both synonymized with nominate, and *hawkeri* (Jifa Medir, in Somalia) with *osiris*. Three subspecies recognized.

Subspecies and Distribution.

C. m. osiris (Finsch, 1870) – locally in Eritrea, Ethiopia, Somalia, SE Sudan (Didinga Mts), N Uganda and N Kenya.

C. m. swahelicus Reichenow, 1891 – locally in C Uganda, extreme E DR Congo, Rwanda, Burundi, C & S Kenya, Tanzania and NE Zambia.

C. m. mariquensis A. Smith, 1836 – WC & S Angola (S from Cuenza Valley) and Namibia E to SW Zambia, Botswana, C & S Zimbabwe, N South Africa and S Mozambique.

Descriptive notes. 11–14 cm; male 9.1–14.2 g, female 7–12.3 g. Male nominate race is metallic green with golden reflections on head to rump, including lesser and median upperside-coverts, and to throat and upper breast; uppertail-coverts metallic dark blue-green; tail very dark brown, all except outer two feather pairs edged metallic green; wing feathers very dark brown, but paler than tail; base of throat ringed by narrow band of iridescent dark violet-blue, below this a purple-maroon breastband (8–10 mm deep) mixed with violet feathering; otherwise black below, including underwing-coverts and axillaries; iris dark

brown; bill and legs black. Female has thin brownish-white supercilium, brown crown, ear-coverts, cheek and upperparts, much darker brown uppertail-coverts and tail, outer tail feather with wide white patch at tip of inner web and white on outer edge; throat and breast dull whitish with variable amounts of heavy black marks, belly also with brown patches, tinged with pale yellow, undertail-coverts buffy-white with black-brown and white streaks, dull white axillaries and underwing-coverts; bare parts as male. Juvenile resembles female, young male distinguished by having black or grey throat bordered white, malar streak and underparts washed yellow, heavy black streaks on breast, yellow-white supercilium and shoulder patch conspicuous, remiges and tertials tipped light brown, broader on secondaries and tertials, central rectrices glossy dark blue with green tinge, outer pair brown with white edges above and below. Race *swahelicus* is shorter-billed than nominate, male has greyer abdomen; *osiris* male has more violet-blue on abdomen and lower edge of throat, broader upper (violet) breastband, darker and narrower lower (maroon) breastband, female more heavily marked on throat and breast. **VOICE.** Complex song may last for a few minutes, involves jumble of “chur-chur”, “chip-chip-chip”, “tsi-tsi”, “b-r-r-r-zi” whistles, warbles and trills. Calls a repeated “chip-chip”.

Habitat. Inhabits dry acacia (*Acacia*) savanna, edges of riverine forest and swamp-fringing forest, as well as gardens and moist woodland. Lowlands and middle elevations; up to 2000 m in Sudan (Didinga Mts).

Food and Feeding. Feeds on nectar; also insects, including flies (Diptera), Lepidoptera, Hymenoptera and termites (Isoptera), as well as spiders (Araneae). Forages singly and in pairs, sometimes with other sunbirds. Visits flowers of genera *Acacia*, *Aloe*, *Bauhinia*, *Cadaba*, *Callistemon*, *Capparis*, *Crotalaria*, *Erythrina*, *Geranium*, *Grevillea*, *Jacaranda*, *Kigelia*, *Kniphofia*, *Leonotis*, *Schotia*, *Tecoma* and *Thevetia*, and mistletoes (Loranthaceae). Takes insects by leaf-gleaning, hawking and hovering.

Breeding. Egg-laying recorded in Mar in Somalia, May in Ethiopia, Feb, Jun, Aug–Sept and Nov in Uganda, all months except Aug and Oct in Tanzania, Feb and Sept–Oct in Zambia, Jan–Jul and Sept–Oct in Zimbabwe, Nov in Botswana, Jul in Mozambique and Aug–Apr in South Africa. Territorial throughout year; males sing from tops of trees near each other, in duetting duels, maintaining upright poses. Courting male flies around female, hovers in front of her and then lands beside her. Nest built by female alone, a thick-walled oval with small porch, made of white down or woolly material and grass, decorated with bark, seeds, flowers and feathers and held together by cobwebs, lined with feathers, suspended 1–8 m up in tree or shrub; same site may be used in successive years or twice in a season. Clutch 1–3 eggs, whitish to greyish-white or greenish-white, heavily marked with pale brown, black, grey or olive streaks, dots, lines and blotches; incubation by female, period 2 weeks; no information on nestling period; fledglings return to nest to roost. Nests parasitized by Diederik Cuckoo (*Chrysococcyx caprius*) and Klaas’s Cuckoo (*Chrysococcyx klaas*).

Movements. Apparently nomadic in Zimbabwe, Mozambique and Uganda. In Uganda presence at Kampala erratic, although noted there in all months. In Zimbabwe moves to C plateau May–Jun to breed, leaving for lower altitudes Nov–Dec. One individual recovered 51 km from ringing site in South Africa. Abandons arid Kalahari areas during droughts.

Status and Conservation. Not globally threatened. Generally common in most of range, but less common in S Tanzania. Occurs in several protected areas, among which are Awash National Park, in Ethiopia, Lake Mburo National Park, in Uganda, Shaba and Buffalo Springs Game Reserve, in Kenya, Serengeti and Tarangire National Parks, in Tanzania, and Etosha National Park, in Namibia.

Bibliography. 72. Shelley's Sunbird

Cinnyris shelleyi

French: Souimanga de Shelley

Spanish: Suimanga de Shelley
German: Scharlachbrust-NektarvogelOther common names: Shelley's Double-collared/Black-bellied Sunbird, Zambesi Valley (Double-collared) Sunbird; Hofmann's Sunbird (*hofmanni*)**Taxonomy.** *Cinnyris shelleyi* Alexander, 1899, Zambezi River, 60 miles [c. 95 km] below junction of Kafue-Zambezi Rivers, on Zambia-Zimbabwe border.Genus often subsumed in *Nectarinia*. May form a superspecies with *C. mariquensis*, and both are sometimes included in a larger superspecies together with *C. congensis*, *C. erythrocerus* and *C. nectarinioides*. It has been suggested that the races may represent two distinct species, and that these may not necessarily be sister taxa; further study required. Two subspecies currently recognized.**Subspecies and Distribution.***C. s. hofmanni* Reichenow, 1915 – E Tanzania.*C. s. shelleyi* Alexander, 1899 – SW Tanzania, extreme SE DR Congo, Zambia, extreme NW Zimbabwe, Malawi and N Mozambique.**Descriptive notes.** 9–13 cm; 8 g. Male nominate race breeding has metallic emerald head, throat and neck with bright yellowish-green, gold and copper reflections, mantle, back and median and lesser upperwing-coverts similar but with less kaleidoscopic reflections; uppertail-coverts dark emerald; remiges, primary coverts, alula, greater wing-coverts and tail dark brown-black, flight-feathers with olive-yellow edges, central rectrices narrowly edged metallic green; thin blue-violet band below green throat, broad (10–15 mm wide) scarlet breastband; belly, flanks and undertail-coverts very dark brown, axillaries andunderwing-coverts brown; iris brown; bill and legs black. Non-breeding male (eclipse plumage) has remiges and rectrices as breeding plumage, and red breastband present and some black may remain on belly; otherwise as female, apart from some metallic feathers on head and mantle and, mainly, on chin, throat and uppertail-coverts. Female is grey-tinged green-brown above, darker on cheek, with thin brownish-white supercilium, tail very dark brown, outermost feather paler and broadly tipped white, remiges dark brown, primaries with dull white edges, secondaries edged pale green; pale brown below, tinged green-yellow posteriorly, chin and throat heavily dark-mottled, dark streaking on breast, flanks and undertail-coverts, brownish-white underwing-coverts and axillaries; bare parts as male. Juvenile both sexes has black chin and throat between pale moustachial stripes, dark upper breast and dark marks on breast and flanks, and more yellow on underparts than female; immature male has scarlet breastband. Race *hofmanni* has bill shorter (18–20 mm) and more curved than that of nominate (20–23 mm), and is smaller with shorter wing (mean 58.5 mm; nominate mean 63.8 mm), male also has scarlet chestband narrower and flanks, belly and undertail-coverts blacker, female greener above with yellowish supercilium, blacker tail, some orange-red on breast, and dusker centres of breast and flank feathers. Voice. Fast warbling song, including “chibbee-cheeu-cheeu” phrase. Calls are a “chip”, a chattering “didi” and a high-pitched “seep-seep”.**Habitat.** Usually in brachystegia (*Brachystegia*) woodland, occasionally in *Baikiaea* or acacia (*Acacia*) woodland and gardens. Occurs in woodland, scrub and gardens at 500–1200 m in E Tanzania (race *hofmanni*).**Food and Feeding.** Nectar, insects, and spiders (Araneae). Forages high in trees. Visits flowers of *Holmskioldia*, *Lagerstroemia*, *Tecoma* and mistletoes (Loranthaceae); forages in *Terminalia* and in *Phragmites* reedbeds.**Breeding.** Laying recorded in Feb and Apr in Tanzania, Aug–Nov in Zambia, Nov in Zimbabwe, and Aug and Oct in Malawi; double-brooded. Nest constructed of leaves, bark and grass or lichen, bound with cobwebs and lined with feathers, which protrude from and hide entrance, positioned 2–3 m up in bush. Clutch 1–2 eggs, pale olive, with fine purple specks or black blotches all over or restricted to wider end. No other information.**Movements.** No data.**Status and Conservation.** Not globally threatened. Locally common to uncommon in Tanzania; uncommon and sparingly distributed in Malawi and Zambia. In Malawi, occurs in Lilongwe Nature Sanctuary, where rare, and in Dzalanama Reserve.**Bibliography.** Baker & Baker (2007), Brooke (1964), Chapin (1954), Cheke & Mann (2001), Dowsett *et al.* (2008), Fry *et al.* (2000), Hall & Moreau (1970), Hooley *et al.* (2005), Irwin (1981a, 2005), Newby-Varty (1945, 1948), Pollard (2001), Skead (1967), Tree *et al.* (1991).

73. Congo Sunbird

Cinnyris congensis

French: Souimanga du Congo

German: Kongonektarvogel

Spanish: Suimanga Congoleño
Other common names: Congo Black-bellied/Long-tailed Congo Sunbird**Taxonomy.** *Nectarinia congensis* van Oort, 1910, Boma, Lower Congo; error = Irebu, Upper Congo, DR Congo.Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. erythrocerus*, and both sometimes included in a larger superspecies with *C. mariquensis*, *C. shelleyi* and *C. nectarinioides*. Monotypic.**Distribution.** PR Congo and DR Congo (forested banks of R Congo and lower R Ubangi).**Descriptive notes.** Male 19 cm, 15.5–19 g; female 11 cm, 15.5–16.5 g. Male is metallic green above, bluer on uppertail-coverts; greater upperwing-coverts black with purple-blue reflection, median and lesser coverts metallic green, remiges black; graduated tail dull black, edged metallic blue-green, narrow elongated central pair of rectrices protrude 46–75 mm; lores black, chin to upper breast metallic green above narrow strip of metallic blue, merging with broad scarlet band (24 mm deep, 15 mm wide) on lower breast; otherwise dull black below, apart from green tips on some flank feathers and undertail-coverts; axillaries and underwing-coverts black; iris dark brown; bill and legs black. Female is dark brown-olive above, with narrow pale line running from above eye to behind eye; tail black-brown with faint green sheen (especially on edges) and brownish feather tips increasing in size towards outer tail, outermost pair with brownish-white distal half of**Habitat.** Forested riverine areas.**Food and Feeding.** Takes small spiders (Araneae), and probably insects and nectar. Visits flowers of *Caesalpinia regia*.**Breeding.** Male seen next to nest suspended from bush 2 m above river and birds in breeding condition in Jul–Dec. No other information.**Movements.** No data.**Status and Conservation.** Not globally threatened. Locally common to rare. Common along banks of R Congo. In DR Congo, fairly common on upper R Congo up to Isengi (at mouth of R Lomami) and on lower Ubangi (S from Impfondo, at least) and lower R Momboyo. Rare and local in PR Congo part of range, where occurs along R Ubangi and R Lefini.**Bibliography.** Bannerman (1948), Borrow & Demeu (2001), Chapin (1954), Cheke & Mann (2001), Fry *et al.* (2000), Hall & Moreau (1970), Rand *et al.* (1959).

74. Red-chested Sunbird

Cinnyris erythrocerus

French: Souimanga à ceinture rouge

Spanish: Suimanga Pechirrojo
German: Schmucknektarvogel**Taxonomy.** *Nectarinia erythrocerus* Hartlaub, 1857, White Nile, S of 8° N, south Sudan.Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. congensis*, and both sometimes included in a larger superspecies with *C. mariquensis*, *C. shelleyi* and *C. nectarinioides*. Monotypic.**Distribution.** S Sudan, E DR Congo, Rwanda, Burundi, Uganda, W Kenya and NW and extreme W Tanzania, with isolated records in C & E Tanzania.**Descriptive notes.** Male 15 cm, 8.2–10 g; female 12 cm, 7.4–9.5 g. Male has head and upperparts metallic green, more blue-green from nape to rump and on scapulars, lores black, uppertail-coverts violet; very dark brown tail tinged glossy blue and edged blue-green, narrow central rectrices protruding 18–25 mm; median and lesser upperwing-coverts iridescent green-blue, rest of wing very dark brown, with faintly bluish glossed edges; thin violet-blue band on upper breast above broader red band, otherwise black below, including underwing-coverts and axillaries; iris dark brown; bill and legs black. Female is green-brown above, with dark mottling on forehead and crown, thin supercilium pale yellow-brown, cheek dark, broad malar stripe green-yellow, very dark brown remiges fringed green-yellow, very dark brown tail graduated and tinged glossy blue; chin and throat heavily mottled dark, underparts pale green-yellow, heavily streaked dark on breast and upper belly, thighs dark green-brown, undertail-coverts brown-white with dark centres, axillaries and underwing-coverts pale green-yellow, latter with dark centres; bare parts as male. Juvenile is as female but greener, young male with blacker chin and throat. Voice. Brief twittering song “tsi-si-sip-see-see-swee” or about seven repetitions of “tsi” followed by “tsip”. Calls include repetitions of “jik” or “trink”.**Habitat.** Edges of rivers and wetlands in savanna areas; also near water in forest, cultivations and gardens. To 1800 m.**Food and Feeding.** Nectar, insects, and spiders (Araneae). Forages generally in pairs. Visits flowers of genera *Erythrina*, *Nectarosia* and *Tamarindus*.**Breeding.** Egg-laying in Feb–Nov in Uganda and Feb, Mar and May in Tanzania. Small, neat, elongated ovoid nest, with or without porch, made from grass, down, leaves, bark and cobwebs, thickly lined with plant down, feathers and wool, adorned externally with leaf skeletons and dead flowers, and suspended 2–5 m up from bush or tree branch. Clutch 1–3 eggs, white, bluish-white or grey with grey or brown streaks and blotches. No other information.**Movements.** No data.**Status and Conservation.** Not globally threatened. Common throughout range in suitable habitat.**Bibliography.** Baker & Baker (2007), Carswell *et al.* (2005), Chapin (1954), Cheke & Mann (2001), Fry *et al.* (2000), Grant & Macleworth-Praed (1943b), Hall & Moreau (1970), Lewis & Pomeroy (1989), Schouteden (1938), Zimmerman *et al.* (1996).

75. Black-bellied Sunbird

Cinnyris nectarinioides

French: Souimanga nectarin

Spanish: Suimanga Ventrinegro
German: Mennigbrust-Nektarvogel

Other common names: Smaller Black-bellied Sunbird

Taxonomy. *Cinnyris nectarinioides* Richmond, 1897, plains east of Kilimanjaro, Tanzania.Genus often subsumed in *Nectarinia*. Has been thought possibly to be part of a superspecies which includes also *C. mariquensis*, *C. shelleyi*, *C. congensis* and *C. erythrocerus*. Has been suggested that this species and *C. pulchellus* link the “*C. mariquensis* complex” with the “*C. chalybea* complex”. Two subspecies recognized.**Subspecies and Distribution.***C. n. erlangeri* (Reichenow, 1905) – extreme SE Ethiopia (banks of R Daua), S Somalia and NE Kenya.*C. n. nectarinioides* Richmond, 1897 – SE Kenya and NE Tanzania.

Descriptive notes. Male 13 cm, female 10 cm; 4–6 g. Male nominate race breeding has head, upperparts, including lesser wing-coverts, and chin and throat metallic golden-green with blue reflections, bases of feathers black, uppertail-coverts dark metallic blue, edges purple occasionally; uppertail black, tinged glossy greenish-blue at edges and with faint glossy blue bands across feathers, elongated central rectrices protrude 16–22 mm beyond the rest; brown-black remiges, primaries browner, secondaries tinged glossy purple-blue; metallic dark purple-blue band on chest above broad (13–19 mm deep) orange-red breastband, pectoral tufts yellow, rest of underparts black, slightly streaked white on flanks; iris brown or black; bill and legs black. Non-breeding male (eclipse plumage) similar to breeding, but upperparts dull brown with green metallic patches, some metallic green on throat, and some whitish-yellow feathers in breastband and underparts. Female is dull yellow-olive above, streaked dark brown on crown and mantle, with yellow streak over eye, dark brown remiges with pale yellow outer edges; tail as male, but outer feathers broadly tipped white on inner margin and with narrow white strip on outer edge, inner web of end of adjoining pair also tipped white, central rectrices not elongated; pale yellow below, chin to throat, side of breast and flanks finely streaked dusky brown to olive-grey, pale yellow malar streak, middle of belly and undertail-coverts pale yellow; bare parts as male. Juvenile is as female, but wing feathers yellower at margins, chin and throat brown-grey and contrasting malar stripe pale yellow, breast mottled, not streaked. Race *erlangeri* male has breastband redder and less deep (12 mm), metallic feathering blue-green, less golden-green, and lacks pectoral tufts. **VOICE.** Song consists of 6–20 “tsk”, “chip” or “che” notes, repeated 6–7 times per second, followed by brief warble of rising and falling “tsi” notes accelerating at end of sequence; whole song repeated during periods of more than three minutes. The “tsk”, “chip” or “che” notes are used also as calls.

Habitat. Arid acacia (*Acacia*) savanna and riverine vegetation. **Food and Feeding.** Nectar, insects, and spiders (Araneae). Forages mainly at higher levels in trees. Visits flowers of acacias, baobab (*Adansonia digitata*) and mistletoes (Loranthaceae, especially genus *Loranthus*). **Breeding.** Nest with egg in late Apr in Somalia; laying recorded in Apr–Aug and Nov in E Africa. Nest purse-shaped, usually with porch and “beard”, made of grass and cobwebs, adorned with bark and dead leaves, lined with feathers or vegetable down, and placed in low tree or bush. Clutch 1–2 eggs, pale olive-grey or olive-brown or yellow-green, densely covered with dark olive-brown stripes and speckles. No other information. **Movements.** No data. **Status and Conservation.** Not globally threatened. Locally common in Kenya and NE Tanzania; uncommon in Somalia; rare in Ethiopia. Possibly occurs also in SW Ethiopia, where reportedly seen at L Abaya; confirmation required. **Bibliography.** Cheke & Mann (2001), Friedmann (1937), Fry *et al.* (2000), Grant & Mackworth-Praed (1943b), Hall & Moreau (1970), Kahindi & Kageci (1995), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Zimmerman *et al.* (1996).

76. Common Purple-banded Sunbird

Cinnyris bifasciatus

French: Souimanga bifascié **German:** Porphyrektarvogel **Spanish:** Suimanga Bandeado
Other common names: Purple-banded Sunbird, Little Purple-banded/(Little) Bifasciated/Short-billed Sunbird

Taxonomy. *Certhia bifasciata* Shaw, 1811, Malembo, Cabinda, Angola. Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. tsavoensis*, and the two are sometimes treated as conspecific. Proposed race *strophium*, described from Manhiça (Sul do Save), in Mozambique, considered indistinguishable from *microrhynchus*. Two subspecies currently recognized.

Subspecies and Distribution.

C. b. bifasciatus (Shaw, 1811) – SW Central African Republic and Gabon S, discontinuously, to W Angola (Cabinda S to Benguela, also Namibe and C Huila). *C. b. microrhynchus* Shelley, 1876 – E DR Congo, Uganda and Kenya S to extreme E Angola (NE Moxico), NE Namibia (Caprivi), extreme N Botswana, E Zimbabwe, Mozambique and E South Africa; Zanzibar and Mafia I, off Tanzania.

Descriptive notes. 9–12 cm; male 6.5–8.1 g, female 6–6.5 g. Male nominate race in breeding plumage has head to throat and upperparts, including lesser and median wing-coverts, metallic green, tinged gold, becoming metallic blue on uppertail-coverts; remiges and greater upwing-coverts black, glossed dark blue, rectrices dark blue, outer webs edged metallic blue-violet; metallic purple-blue upper breastband above second band of purple-red or red-maroon (6–9 mm deep), otherwise brown-black below; iris dark brown; bill and legs black. Non-breeding male retains breeding plumage on wings and tail, with some metallic feathers still on upperparts, head, throat and breast, and some black feathers on abdomen. Female lacks iridescence, is all greyish-olive above apart from narrow white stripe above eye, lores darker than forehead, wing dark brown, remiges narrowly edged yellowish-olive, blue-black tail, outermost two pairs of rectrices edged white or pale grey; chin and throat whitish, slight olive tinge on throat, otherwise pale yellow below, with dark streaks on breast, axillaries white, tipped pale yellow, underwing-coverts white, washed yellow; bare parts as male. Immature male is darker brown above than adult female, has chin and throat black, otherwise yellowish below with heavy black mottling, first metallic feathers appear on lesser wing-coverts and throat; immature female as adult but darker brown on upperparts, with throat and breast grey, abdomen with yellow wash. Race *microrhynchus* male is brighter green, less bronzy, on head and upperparts and has maroon breastband broader (8–12 mm deep) and more violet than nominate, female more heavily streaked below, both sexes have shorter bill (male 16–20 mm) than nominate (male 21.5–23 mm). **VOICE.** Song consists of either high-pitched descending “titiitititi-trooo” trill, occasionally preceding a

warble, or repetitions of 0.5-second sequences of “treeee-ti-ti-tooo”. Male call “b-r-r-r-zi”, to which female responds with “b-r-r-r”; another call is “tsikit-y-dik”.

Habitat. Coastal and riverine habitats, savanna woodland, broadleaf woodland, miombo woodland, dry forest, moist evergreen forest, cultivation, grassland and gardens.

Food and Feeding. Nectar, seeds and insects. Also takes spiders (Araneae) from webs and feeds them to fledglings. Forages singly and in pairs; often mixed with other sunbirds. Visits flowers of *Acacia albidia*, *Albizia*, aloes (*Aloe*), *Cassia singuena*, *Leonotis*, *Manihot glaziovii*, *Mimusops caffra*, *Punica granatum*, *Syzygium cordatum*, *Tecoma mollis* and mistletoes (Loranthaceae).

Breeding. Egg-laying recorded in May and Oct in Angola, Aug in DR Congo, Jun and Aug–Sept in Uganda, Jul in Kenya, Jan and Aug–Sept in Tanzania, Mar–Dec in Zanzibar, Jan and Aug–Nov in Zambia, May and Aug–Oct in Malawi, Mar, Jun and Sept–Dec in Zimbabwe, and Sept–Nov in Mozambique and South Africa. Small ovoid nest made of grass, fibres, down and cobwebs, extravagantly adorned with leaves, lichens and seeds and often with “beard”, lined with feathers and down, and suspended 1–10 m up in e.g. tree or bamboo. Clutch 1–2 eggs, white to pale grey or dark greenish or purple-grey, with darker grey streaks and black, purple or grey speckles and lines concentrated at wider end; no information on duration of incubation and nestling periods; both parents feed nestlings.

Movements. Resident and migratory. In NE Gabon present Feb–May. In South Africa present as far S as Durban only during austral winter. In Zimbabwe, leaves lowveld in Apr–Jul and moves to highveld, returning Nov–Jan, when some may go as non-breeders to S Mozambique Nov–May. In Tanzania, ascends to higher elevations in cooler season.

Status and Conservation. Not globally threatened. Common in most of geographical range, but less so in DR Congo, Kenya, Uganda, Tanzania and S Zambia. Range of *microrhynchus* possibly extends N to S Sudan, S Ethiopia and S Somalia, but possible confusion in those areas with *C. tsavoensis* unresolved; field study required. Occurs in several protected areas, e.g. Mikumi National Park, in Tanzania, and Mkuze Game Reserve, in South Africa.

Bibliography. Baker & Baker (2007), Benson (1944), Borrow & Demey (2001), Brooke (1970b), Chapin (1954), Cheke & Mann (2001), Clancey (1979a), Clancey & Williams (1957), Edwards (1988), Fry *et al.* (2000), Hall & Moreau (1970), Hamner (1981, 1989), Hockey *et al.* (2005), Jones (1996), Lewis & Pomeroy (1989), Prinzing *et al.* (1989), Sclater & Moreau (1933), Shead (1967), Tree (1991, 1997b), Zimmerman *et al.* (1996).

77. Tsavo Purple-banded Sunbird

Cinnyris tsavoensis

French: Souimanga du Tsavo **German:** Tsavonektarvogel **Spanish:** Suimanga del Tsavo

Taxonomy. *Cinnyris bifasciatus tsavoensis* van Someren, 1922, Tsavo, Kenya.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. bifasciatus*, and sometimes treated as conspecific. Monotypic.

Distribution. E Kenya and NE Tanzania.

Descriptive notes. 9–11 cm; 6–7.6 g. Male has head to throat and upperparts, including median and lesser wing-coverts, iridescent green, rump and uppertail-coverts blue; very dark brown rectrices, slightly glossed on top, with metallic green margins, remiges black; two narrow breastbands, upper one (2 mm deep) violet, lower one (3–5 mm deep) maroon, otherwise underparts, including underwing-coverts and axillaries, black; iris, bill and legs black. Female is grey-green above, with narrow brown-white supercilium, grey-brown cheek, long whitish malar stripe; tail darker and slightly glossy, outer three pairs of rectrices

tipped whitish, whitish edges on outermost feather pair, wings dark brown, edged olive, grey tips on median and lesser wing-coverts; throat pale creamy, underparts pale brownish-white, breast streaked grey-brown, yellow wash below, underwing-coverts and axillaries off-white; bare parts as male. Juvenile is as female, but has darker chin and throat and contrasting pale malar stripes, dark brown barring on abdomen. **VOICE.** Song consists of rapid sequence of “tsusitiseesee, chuchiti-tsi-tsi-tsi-tsi-tsitisee-see-see-see-chitisee” or similar.

Habitat. Dry savanna with acacia (*Acacia*) or *Commiphora*, and riverine woodland.

Food and Feeding. Nectar and insects. Forages singly and in pairs. Visits flowers of *Delonix elata*. Gleans items from small branches; also catches insects in flight.

Breeding. Egg-laying in Oct in Kenya. Compact ellipsoid nest made of strips of wood, grasses, bark, dried acacia buds and twigs, held together with cobwebs, suspended 2 m above ground near end of small branch of acacia. Clutch 1 egg, matt pale grey, with darker grey blotches and spots concentrated at wider end, superimposed with fine grey-brown spots and speckles. No other information available.

Movements. No data.

Status and Conservation. Not assessed. Generally not uncommon. Fairly common in Tsavo National Park, in Kenya. Possibly present also in S Sudan, S Ethiopia and S Somalia, but whether individuals recorded in those areas are of this species or *C. bifasciatus* is unresolved; research needed.

Bibliography. Cheke & Mann (2001), Clancey & Williams (1957), Fry *et al.* (2000), Hall & Moreau (1970), Lack (1985), Serle (1943a), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

78. Violet-breasted Sunbird

Cinnyris chalcornelas

French: Souimanga à poitrine violette **Spanish:** Suimanga Pechivioleta
German: Veilchenbrust-Nektarvogel

Other common names: Kenya Violet-breasted Sunbird

Taxonomy. *Cinnyris chalcornelas* Reichenow, 1905, Kismaayo, southern Somalia.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. pembae*, and often considered conspecific. Also, a possible relationship with *C. notatus* has been proposed. Monotypic.

Distribution. S Somalia and SE Kenya.

Descriptive notes. 11–12 cm; 7–9.5 g. Male breeding has head and upperparts, including median and lesser wing-coverts, iridescent emerald-green, uppertail black with slight blue gloss, remiges blue-black; chin and throat iridescent blue-green, broad (7–8 mm deep) band on upper breast violet, otherwise black below, including underwing-coverts and axillaries; iris dark brown; bill and legs black. Non-breeding male retains blue-black remiges and tail and iridescent wing-coverts, but

otherwise as female except for iridescent green patches interspersed on grey-brown plumage of back, crown and cheeks, grey line 3 mm broad from base of bill to lower chest, and grey patches in black of belly. Female has brownish-white supercilium, brown cheek, with crown and upperparts grey-brown, tinged green, uppertail-coverts darker, very dark brown rectrices slightly glossy above, variably some with whitish tips, outermost pair with narrow whitish outer margin, dark grey-brown remiges with greyish margins; pale brownish-white below, slightly streaked on throat, breast and flanks, with yellow wash on centre of abdomen, underwing-coverts dark brown, axillaries off-white; bare parts as male. Juvenile male resembles adult female, but has black throat with iridescent green centre, iridescent green shoulder patch, some black on lower belly, and broad white margins on outer edges of inner primaries. VOICE. Trilling song as "chrrrrrrrrsssswwzzzzlllll" or slower sequence of notes, ending with "chee-per-chichi-woo-per-chichi-chee-dzurr". Calls "chip" and "chut".

Habitat. Coastal thornbush.

Food and Feeding. Few data. Diet presumably includes nectar and insects. Forages singly and in pairs, at times in small groups; one group of 100 individuals seen at acacia trees (*Acacia*). Visits flowers of acacias, *Hibiscus* and *Millingtonia*.

Breeding. Nestlings in Dec and nest-building observed in Apr, Jul and Oct in Somalia. Female alone builds nest. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Locally fairly common in Somalia; rather uncommon in Kenya.

Bibliography. Ash & Miskell (1998), Cheke & Mann (2001), Clancey & Williams (1957), Fry *et al.* (2000), Hall & Moreau (1970), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

79. Pemba Sunbird

Cinnyris pembae

French: Souimanga de Pemba **German:** Pembanektarvogel **Spanish:** Suimanga de Pemba
Other common names: Pemba Violet-breasted/Pemba Purple-banded Sunbird

Taxonomy. *Cinnyris pembae* Reichenow, 1905, Pemba Island.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. chalcomelas*, and often considered conspecific. Also, a possible relationship with *C. notatus* has been proposed. Monotypic.

Distribution. Pemba I and adjacent islets, off E Tanzania.

Descriptive notes. 9–10 cm. Male has head and upperparts, chin and throat iridescent green with blue reflections; lesser upperwing-coverts purple, largest outer lesser coverts and median coverts iridescent green, rest of wing black, with narrow metallic green edges on greater coverts; glossy violet band on upper breast, remaining underparts, underwing-coverts and axillaries black; iris dark brown; bill and legs black. Female is greenish grey-brown above, with white supercilium, uppertail grey-brown, glossed dark blue, with dark olive margins, T3–T5 with white tips, outermost feather with white patch at tip of inner web and white edge

on outer web; remiges dark grey-brown with pale yellow margins; pale cream or yellow below, yellower on belly and sometimes towards vent, underwing-coverts and axillaries white; bare parts as male. Juvenile is as female, but chin and throat darker, has broad off-white malar stripe and grey mottling below. VOICE. Song consists of up to 15 "tslink" notes before warble of rising and falling notes. Calls repetitive "tslink-tslink-tslink" or "tslunk".

Habitat. Varied, with no particular preferences. Found in tropical moist forest dominated by *Odyenda zimmermannii*, coastal rag scrub, clove and rubber plantations and farmland. Visits habitations.

Food and Feeding. Insects; also nectar, and berries of *Flueggia virosa* and fruits of *Areca catecha*. Visits flowers of *Carica papaya*, *Cocos nucifera*, *Manihot esculenta*, *Musa*, *Phoenix reclinata* and *Syzygium aromaticum*.

Breeding. Egg-laying in May–Jan. Thick-walled, purse-shaped nest, lined with down from *Imperata cylindrica*, without "beard", suspended 1–2 m up in shrub. Clutch 2 eggs, green-white with ashy-brown streaks and blotches. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Restricted-range species: present in Pemba EBA. Common on Pemba and nearby small islands.

Bibliography. Archer & Parker (1993), Archer & Turner (1993), Baker & Baker (2007), Catry *et al.* (2000), Cheke & Mann (2001), Clancey & Williams (1957), Fry *et al.* (2000), Hall & Moreau (1970), Lewis & Pomeroy (1989), Pakenham (1979), Zimmerman *et al.* (1996).

PLATE 16

cm 5

80. Orange-tufted Sunbird

Cinnyris bouvieri

French: Souimanga de Bouvier **German:** Bouviernektarvogel **Spanish:** Suimanga de Bouvier
Other common names: Bouvier's (Orange-tufted) Sunbird, Southern Orange-tufted Sunbird

Taxonomy. *Cinnyris bouvieri* Shelley, 1877, Landana, Cabinda, Angola. Genus often subsumed in *Nectarinia*. Has been thought perhaps to form a superspecies with *C. osea*, *C. oustaleti*, *C. talatala* and *C. asiaticus*. Birds from W shore of L Tanganyika, in E DR Congo, described as race *tanganyicae*, but considered inadequately differentiated from birds elsewhere in species' range. Monotypic.

Distribution. Scattered localities from SE Nigeria (Obudu and Mambilla Plateaux) and W & C Cameroon S to Equatorial Guinea, S & E Gabon, PR Congo and N Angola, E to W & S Central African Republic, DR Congo, Uganda, extreme W Kenya, NW Tanzania and NW Zambia.

Descriptive notes. 11–12 cm; 7–10 g. Male is metallic green above, except for metallic purple forehead, copper-tinged green ear-coverts and bluer uppertail-coverts; dark brown wing feathers, including greater wing-coverts; black tail, central feathers glossed dark blue and with metallic green edges on both webs, other rectrices except outermost pair with metallic green edges on outer webs; chin and upper throat dull black, bordered with metallic purple, lower throat and upper breast metallic green, narrow purple band on chest above broader dark maroon band; pectoral tufts orange above and lemon-yellow below, rest of

underparts, including axillaries and underwing-coverts, dark brown; iris dark brown; bill and legs black. Female is mouse-brown above, with indistinct olive wash on rump, sometimes a pale supercilium present; upper tips of tertials edged off-white and outer edges of secondaries edged buff, black tail, outer feathers of which edged and tipped white; grey-brown chest streaked yellow, belly pale yellow, undertail-coverts and underwing-coverts pale yellow, axillaries a mixture of pale yellow and white; bare parts as male. Immature male is as adult female, but throat and breast darker and belly less yellow. **VOICE.** Song begins with quiet "tswee" before a louder "tsi" and then a warble terminating in "tsi-pu, tsi-pu, tsi-pu, tsi-pu, tsi-pu, tsi-pu tsi" or "chieta-chieta-chieta-chit" or similar; some notes may be repeated in sequences lasting for more than 2 minutes. Calls include "cheep", "ziet" and "chip-ip".

Habitat. Varied, including grassland, savanna woodland, forest edge and plantations; to 2050 m. **Food and Feeding.** Nectar and insects. Forages singly, but sometimes in groups; occasionally with other sunbirds. Visits flowers of *Acanthus*, *Erythrina*, *Manihot glaziovii* and leguminous shrubs.

Breeding. Egg-laying recorded in Oct in Cameroon, Nov in Kenya, Jun in DR Congo, and Mar in Zambia. Purse-shaped nest made of grass and cobwebs, lined with down, suspended from thistle, bush or grass. Clutch 2 eggs. No other information.

Movements. Unknown. Some possible migration, as records in Gabon and Uganda apparently seasonal, but timing of records could be attributable also to species' scarcity.

Status and Conservation. Not globally threatened. Generally uncommon. Locally common in NW parts of range, e.g. at edge of montane forest in Nigeria and in N highlands of Cameroon.

Bibliography. Baker & Baker (2007), Bannerman (1948, 1951), Benson (1966), Benson & Irwin (1966), Benson *et al.* (1971), Borrow & Deme (2001), Brosset & Éard (1986), Chapin (1954), Cheke & Mann (2001), Fry *et al.* (2000), Hall & Moreau (1970), Lippens & Wille (1976), Lynes (1938), McCarthy (2006), Rand *et al.* (1959), Serle (1950, 1957), Zimmerman *et al.* (1996).

81. Palestine Sunbird

Cinnyris osea

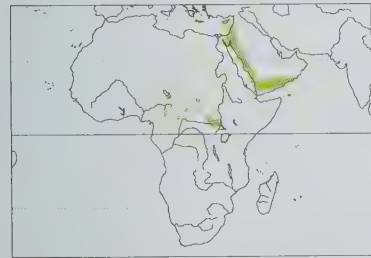

French: Souimanga de Palestine **German:** Jerichonektarvogel **Spanish:** Suimanga Palestino
Other common names: (Northern) Orange-tufted Sunbird; Chad Orange-tufted Sunbird (*decorsei*)

Taxonomy. *Cinnyris osea* Bonaparte, 1856, "Plaines de Jéricho" = Palestine. Genus often subsumed in *Nectarinia*. Has been thought perhaps to form a superspecies with *C. bouvieri*, *C. oustaleti*, *C. talatala* and *C. asiaticus*. Proposed race *butteri* (described from Kajo Kaji, in S Sudan) considered inseparable from *decorsei*. Two subspecies recognized.

Subspecies and Distribution.

C. o. osea Bonaparte, 1856 – Lebanon, Israel, Palestine, NE Egypt, S Syria, Jordan, W Saudi Arabia, Yemen and S Oman.

C. o. decorsei Oustalet, 1904 – widely scattered localities at L Chad and in E Cameroon, Central African Republic, W & S Sudan, NE DR Congo and NW Uganda.

Descriptive notes. 8–10 cm; male average 7.6 g and female average 6.8 g (nominate). Male nominate race breeding has purple forehead, metallic blue-green (blue in some lights) on rest of head and upperparts, except for dark metallic blue uppertail-coverts; tail as back, lesser and median upperwing-coverts metallic green, rest of wing dark brown; side of face metallic green, chin black, throat metallic purple with green gloss in lower section, breast violet with gold reflections, pectoral tufts orange-red above and yellow below; rest of underparts, including underwing-coverts, black, lower breast and belly with metallic tinge; iris

dark or dark brown; bill and legs black. Male non-breeding resembles female below, but wings and tail as in breeding plumage, underparts dull black with iridescent patches, and some white near tail. Female is dull grey-brown above with indistinct bluish-green tinge on rump, darker brown wing-coverts, tail black glossed blue; light greyish-brown below, belly very faintly washed yellow,

axillaries pale yellow, underwing-coverts grey-white mixed with yellow and brown, no pectoral tufts; bare parts as male. Immature male is like adult female but brighter yellow on belly, when moulting into breeding plumage has dark areas broken up by white and metallic green patches; immature female as adult but more yellow on underparts. Race *decorsei* is smaller than nominate, male lacks iridescence on lower breast and belly, no non-breeding plumage known, female is darker and browner (less grey) above and with indistinct olive tinge on rump, light brown with yellow tinge below. **VOICE.** Song of race *decorsei* described as "chwing-chwing-chwing..." or "chwee-chwee-chwee...", that of nominate much more varied and with dialects; repertoire includes repetitions of "tsk, tsk, wee, wee, wee, tsk-choo, choo, choo", a warble of fast high-pitched rising and falling notes and various trills and whistles, in addition to mimicry of songs of other bird species. Calls of nominate include "tsk", "tchoo-twit", "tiu", "fifi", "seep seep", "seep tehink tehink", "pee-pee", "dzee" and "teweeit te-weeit"; of *decorsei* "chip-ip-ip-ip".

Habitat. Savannas, bushy riversides, rocky valleys, gardens and parks, orchards, juniper (*Juniperus*) woods and cypress (*Cupressus*) groves. In Yemen, absent at sea-level but occurring at 250–3200 m.

Food and Feeding. Nectar, fruits, seeds, also spiders (Araneae) and insects. Forages singly and in pairs; sometimes gregarious outside breeding season, when small groups of up to eight individuals observed to feed together. Visits flowers of many genera, including *Acacia*, *Aloe*, *Anagallis*, *Anchusa*, *Bauhinia*, *Begonia*, *Bougainvillea*, *Capparis*, *Citrus*, *Clerodendrum*, *Cordia*, *Convolvulus*, *Cordia* (*Cordia abyssinica*), *Cytisus*, *Echinops*, *Euphorbia*, *Hibiscus*, *Jasminum*, *Lavandula*, *Nolana*, *Lonicera*, *Loranthus*, *Lupinus*, *Lycium*, *Malvaviscus*, *Moringa*, *Nerium* (oleander), *Nicotiana*, *Orostegia*, *Phoenix*, *Plicosepalus*, *Punica*, *Pyrostegia*, *Robinia*, *Tecoma*, *Thevetia*, *Yucca*, *Zinnia* and *Zygophyllum*. Feeds by perching on plants, and by hovering in front of flowers.

Breeding. Egg-laying recorded in Apr–May in Lebanon and Jordan, Feb–Sept in Israel. Feb, Mar and May in Arabia, Jun in Egypt and Nov–Dec in Sudan, and breeds Jan–Feb in N DR Congo; two or three broods. Forms pair-bonds and holds territory, but male promiscuous, up to at least six males following receptive female for as long as 4 days before laying begins; rivals have singing duels and commit infanticide. Courting male approaches female, exposes pectoral tufts, and jerks up and down, with head held erect and neck outstretched, while spreading tail and drooping wings.

Nest built by female alone, taking 8–21 days, an untidy and pear-shaped structure made from grass, stems, roots, leaves, down, bark, paper and polythene shreds, bound with hair, wool and cobwebs, and with "beard" of leaves and twigs, lined with feathers, wool, leaves and bits of paper, suspended 0.5–1.0 m up in bush; territory 0.3–14.3 ha. Clutch 1–3 eggs, rarely 4, slightly glossy, white, covered with fine grey or grey-brown or red-brown or yellow-green spots, concentrated at wider end; incubation by female, leaving nest four times per hour during daylight, incubation period 12–14 days; chicks brooded by female, fed by both parents, both also remove faecal sacs, nestling period 13–14 days; fledglings return to roost in nest for 7–10 days after leaving nest.

Movements. Nominate race mostly resident, but wanders and makes altitudinal movements, e.g. in Jordan and Oman; some visit Syria in non-breeding season. Race *decorsei* ascends to higher altitudes (2000–3000 m) in Sudan (Jebel Marra) to breed during Sept–Jan; breeders present in Uelle grasslands, in N DR Congo, only in Oct–Mar, but non-breeding destinations unknown.

Status and Conservation. Not globally threatened. Uncommon in much of range; locally common, and in some places abundant, especially in N of range. Very common and widespread in Israel and Palestine, where population increased during last century; locally common in Jordan, where densities of 2–8 pairs/km²; common above 1500 m in SW Saudi Arabia and at 250–2800 m in N Yemen. Has increased numbers and expanded range in S Syria following establishment of settlements.

Bibliography. Andrews *et al.* (1999), Baha el Din (1985), Borrow & Deme (2001), Chapin (1954), Cheke & Mann (2001), Cramp & Perrins (1993), David & Gosselin (2002b), Eisikowitch & Nahari (1982), Eriksen (1998), Fry *et al.* (2000), Gallagher & Woodcock (1980), Goldstein & Yom-Tov (1988), Goldstein *et al.* (1986), Hall & Moreau (1970), Hambly *et al.* (2007), Harrison (1975), Kumerloeve (1960), Leader *et al.* (2000, 2005), Markman, Pinshow & Wright (1999), Markman, Tadmor-Melamed *et al.* (2006), Markman, Yom-Tov & Wright (1995, 1996), Nikolaus (1987), Paz (1983), Rahmani *et al.* (1994), Ramadan-Jaradi *et al.* (2008), Roxburgh & Pinshow (2000), Sclater & Mackworth-Præd (1918), Shirihai (1996), Tadmor-Melamed *et al.* (2004).

82. Shining Sunbird

Cinnyris habessinicus

French: Souimanga brillant **German:** Glanznektarvogel **Spanish:** Suimanga Brillante
Other common names: Abyssinian Sunbird

Taxonomy. *Nectarinia habessinica* Hemprich & Ehrenberg, 1828, Eilat, Eritrea. Genus often subsumed in *Nectarinia*. Five subspecies recognized.

Subspecies and Distribution.

C. h. habessinicus (Hemprich & Ehrenberg, 1828) – NE Sudan, Eritrea and N & C Ethiopia.

C. h. kinnearyi Bates, 1935 – W Saudi Arabia (S Hijaz S to Asir).

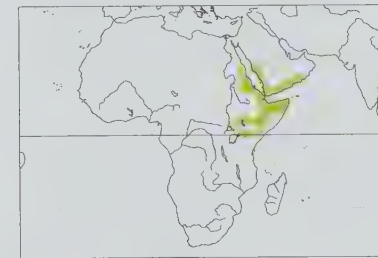

C. h. hellmayri Neumann, 1904 – extreme SW Saudi Arabia, Yemen and SW Oman.

C. h. alter Neumann, 1906 – E Ethiopia and N Somalia.

C. h. turkanae van Someren, 1920 – SE Sudan, NE Uganda, Kenya, S Ethiopia and S Somalia.

Descriptive notes. 13 cm; male 9.5–11.5 g, female 7–11 g. Male nominate race has purple forehead, otherwise head and upperparts iridescent green, with golden sheen above and on chin to upper breast, also lesser and median wing-coverts, uppertail-coverts bluer; rectrices black, tinged violet, central pair with narrow metallic green margins, upperwing dull black with violet tinge; thin blue-green band above broad (7.5–11 mm deep) scarlet breast-band, latter bordered below by narrow iridescent dark blue band, pectoral tufts yellow, otherwise black below, including underwing-coverts and axillaries; iris dark brown; bill and

legs black. Female has crown and upperparts pale grey-brown, uppertail-coverts darker, dark brown tail with faint blue tinge, inner webs of two outer pairs of rectrices tipped off-white, remiges dark grey-brown, edged buff; chin grey-white, otherwise pale brown-grey below, with slight mottling on throat and breast, yellow tinge on belly, dark streaks centrally on grey-white undertail-coverts, whitish underwing-coverts darker at bases, light brown axillaries; bare parts as male. Juvenile resembles female, but with black throat (darker in male), bordered off-white, reaching onto breast;

immature often with dark centres of breast feathers, male with chin to neck metallic green and indications of red chestband. Race *alter* male has slightly deeper breastband (9–13 mm) bordered metallic blue or violet-green, and larger bill (22.5–25 mm; nominate 18.5–20.5 mm), female darker than nominate and often with greenish-orange breastband; *hellmayri* male has crown metallic blue, breastband made indistinct by subterminal green-blue bars (suggesting narrow red collar below metallic throat), female darker than previous; *kinneari* male has shorter bill (18.5–20 mm) than last (21.5–23.0 mm), red breastband less obscured by blue subterminal bars, female very dark, more black-brown, and appears scaly (especially on throat, belly and undertail-coverts); *turkanae* male has broader (14–19 mm deep) and paler red breastband than nominate, with imperceptible or no metallic fringe, female with palest underparts of all. Voice. Song a warbling sequence of fast “eh eh eh ch ch” preceding series of attenuated “chee-chee-chee”. Calls include sharp “tsp, tsp, tsp” notes. **Habitat.** Dry thornbush and dry riverbeds with flowering plants, cultivations, gardens, rocky hill-sides and montane forest; sea-level to 1800 m.

Food and Feeding. Nectar, fruits of *Salvadora persica*; insects and spiders (Araneae). Forages singly, in pairs and in groups; sometimes large flocks of up to 75 individuals. Visits flowers of *Acacia*, *Alone*, *Calotropis procera*, *Capparis decidua*, *Delonix elata*, *Ficus*, *Phoenix dactylifera*, *Salvia*, *Stereospermum*, *Ziziphus spina-christi* and others. Feeds by perching on plants and by hovering in front of flowers.

Breeding. Laying recorded in Mar–Jul in Arabia, Dec–Jan in Sudan, Dec–Feb in Eritrea, Apr in Ethiopia, Feb–May Somalia and Apr–Jul in Kenya; sometimes double-brooded. Displaying male stretches up and shuffles along perch towards female, then swings body from side to side before suddenly fluffing out plumage and exposing pectoral tufts; may take off vertically and return to perch to sing. Nest built by female, oval in shape and with distinct porch, made from fibres, grass, leaves, insect cocoons and cobwebs, lined with plant wool (from seeds of *Ipomoea* or *Calotropis*) and feathers, suspended 1–7 m up in thorny tree or shrub, e.g. *Euphorbia*. Clutch 1 egg, white, with pale grey-brown blotches and black scrawls at wider end; nestling fed by both sexes; no information on incubation and nestling periods.

Movements. Wanders in search of flowering plants.

Status and Conservation. Not globally threatened. Very common in N of range, e.g. Red Sea hills of Sudan; becomes uncommon in S, e.g. in N Kenya. Occurs in Awash National Park, in Ethiopia, and in Buffalo Springs National Reserve and Shaba Game Reserve, in C Kenya.

Bibliography. Al Safadi & Kasperek (1995), Archer & Goodman (2001), Cheke & Mann (2001), Eriksen (1998), Friedmann (1937), Fry *et al.* (2000), Gallagher & Woodcock (1980), Granichi (1988), Hall & Moreau (1970), Lewis & Pomeroy (1989), Meinertzhagen (1954), Rahmani *et al.* (1994), Williams (1954), Zimmerman *et al.* (1996).

83. Splendid Sunbird

Cinnyris coccinigastrus

French: Souimanga éclatant **German:** Rotbauch-Nektarvogel **Spanish:** Suimanga Espléndido

Taxonomy. *Certhia coccinigastra* Latham, 1801. Africa – Senegal.

Genus often subsumed in *Nectarinia*. Monotypic.

Distribution. Senegal E to S Sudan and NE DRCongo, and NC Gabon.

Descriptive notes. 13–14 cm; 12.3–15.3 g. Male has forehead to centre of crown and ear-coverts metallic purple, lores black, back of head metallic steel-blue, lower neck, mantle, scapulars, back, rump, and lesser and median upperwing-coverts metallic golden-green, uppertail-coverts steel-blue, some edged purple; remiges and greater wing-coverts black; black tail edged metallic steel-blue or green on outer webs; side of face and throat metallic purple, breast metallic steel-blue with scarlet feather edges (appearing barred), long pale yellow pectoral tufts; rest of underparts, including axillaries and underwing-coverts, black.

undertail-coverts broadly tipped metallic steel-blue; iris dark brown; bill dark brown or black; legs blackish-purple or black. Female has grey forehead, lores, cheeks and ear-coverts dark olive, faint white stripe over eye, otherwise olive-washed grey-brown above, upperwing dark brown, edged olive-green, inner secondaries with pale tips, tail black-brown with green sheen, all rectrices except central pair with narrow white tip; chin and throat white, underparts pale yellow with grey feather centres (appearing mottled), but centre of belly pure yellow, axillaries pale yellow, underwing-coverts white, some tipped yellow; iris dark brown, bill and legs greenish-black. Immature male is as adult female but without grey forehead, and has upperparts browner, chin and throat grey-black (glossy purple on subadult), bill dark brown; immature female has darker brown crown than adult, throat patch less extensive than on young male, underparts duller, breast darker. Voice. Common song a series of 6–9 clear descending whistles, “chip-chee-cho-cho-choo-choo-choo” or “pitew-tew-pitew-pitew-pitew”, alternative song of 6–8 notes rendered as “Oh—what a splendid-bird-I am”; local variations in dialect maintained for up to 3 years, but not after 30 years, and some males only 40 m apart sing different dialects. Fluty calls, chirps and plaintive “chee-tee, chip, tsehp” and “choo”; “djew-djew-djew” as alarm.

Habitat. In most habitats from coast to N Guinea savanna, except mature forest.

Food and Feeding. Nectar, seeds, also spiders (Araneae) and insects, including flying ants (Formicidae) and termites (Isoptera), taken in the air. Forages singly and in pairs, also sometimes in groups of twelve or more individuals in flowering tree. Visits flowers of *Berlinia grandiflora*, *Bombax*, *Caesalpinia pulcherrima*, *Carica papaya*, *Manihot glaziovii*, *Milletia thomingii* and *Parkia*. Hovers at flowers and leaves; probes bark of oil palm (*Elaeis guineensis*) to take sap.

Breeding. Egg-laying recorded in Sept–Oct in Senegal and Sierra Leone, Jul–Oct in Gambia, Mar–Apr, Jun, Sept–Oct and Dec in Ghana, and Mar–Jun in Nigeria; sometimes double-brooded. Territorial male sings from regular perches and performs courtship song flights before landing high up, to be joined on branch by female, latter holding tail depressed and wings drooped. Nest built by female alone, pouch-shaped and with porch, made of fibres, grass, bark, down and cobwebs, lined with down, suspended from thin branch 2–3 m up. Clutch 1–2 eggs, matt and varying in colour from pale grey to dark brown, with grey and brown mottles, streaks, speckles and blotches concentrated at wider end; incubation of eggs and rearing of young by female alone; no information on duration of incubation and nestling periods.

Movements. Resident and migratory. In W Africa, migratory populations tend to move N to N savanna during May–Oct wet season, returning S in Dec–Apr; in Liberia, however, reported in N only in Oct–Jan and in Burkina Faso only Nov–May. Present NE: Gabon Sept–Nov.

Status and Conservation. Not globally threatened. Common throughout most of range. Occurs in several protected areas, such as Comoé National Park, in Ivory Coast.

Bibliography. Blancou (1939), Borrow & Demeey (2001), Bouet (1942), Chapin (1954), Cheke & Mann (2001), Fry *et al.* (2000), Girmes (1974, 2007), Grote (1924), Hall & Moreau (1970), Payne (1978), Schnell *et al.* (1985), Serle (1950, 1956, 1957), Traylor & Parelius (1967), Walsh *et al.* (1990).

84. Johanna's Sunbird

Cinnyris johannae

French: Souimanga de Johanna

Spanish: Suimanga de Johanna

German: Grünscheitel-Nektarvogel

Other common names: Madame Verreaux's Sunbird

Taxonomy. *Cinnyris johannae* J. Verreaux and É. Verreaux, 1851. Gabon.

Genus often subsumed in *Nectarinia*. Racial affiliation of populations in Nigeria uncertain; tentatively included in nominate, but further study required. Two subspecies recognized.

Subspecies and Distribution.

C. j. fasciatus (Jardine & Fraser, 1852) Sierra Leone and SW Mali E to SW Benin.

C. j. johannae J. Verreaux & É. Verreaux, 1851 – SW & SE Nigeria and S Cameroon E to Central African Republic and NE DRCongo, and S to PRCongo and NW Angola (Cabinda).

Descriptive notes. 13–14 cm; male 12.6–14.7 g, female 11–15 g. Male nominate race has lores black, rest of head to upper throat and upperparts, including lesser and median upperwing-coverts, metallic golden-green, greater wing-coverts and remiges black, tail black with blue-purple sheen; metallic purple lower throat and upper breast above dark crimson middle and lower breast and upper flanks, feathers in upper section of breast with metallic purple subterminal bands; large pectoral tufts lemon-yellow, rest of underparts, axillaries and underwing-coverts black; iris dark brown; bill black; legs black, yellow on soles.

Female has head and upperparts dark brown-olive, rump brown with olive edging, narrow creamy supercilium and thin dark eyestripe, dark olive lores, dark grey-brown upperwing, remiges narrowly edged olive, tertials and wing-coverts narrowly edged pale olive, tail black-brown with brown-white tips, tips broader on outer two feather pairs; chin and throat cream-coloured, thinly streaked dark brown, underparts light yellow and heavily streaked, streaks heaviest (and dark olive-grey) on breast and flanks, abdomen pale olive-yellow, undertail-coverts pale olive-yellow with dark olive-grey streaks, axillaries pale yellow, inner underwing-coverts white and outer ones brown, mottled white; iris dark brown, bill and legs black. Immature male is as adult female, with striped underparts, but grey streaking denser and side of throat, flanks and breast darker. Race *fasciatus* is very like nominate, but male has lighter red on underparts and female is generally less dark. Voice. Song a complex high-pitched warble of rising and falling whistling notes. Calls include “wit”, singly or many in quick succession, also a descending “tsiooooo” and “tswee”.

Habitat. Mature forest, secondary forest, clearings, gardens and cocoa plantations.

Food and Feeding. Insects, spiders (Araneae), pollen, fruits of *Macaranga assava* and *Macaranga barteri*, and nectar. Forages singly and in groups of up to five individuals; mostly in upper levels of vegetation. Visits flowers of *Anthocheista*, *Psydrax*, *Syzygium congolense* and mistletoes (Loranthaceae); looks for insects in *Usnea* lichen.

Breeding. Egg-laying recorded in May in Liberia and Jul in Ghana. Messy nest with loose “beard”, made of bark and moss or lichen, held together by fungal fibres, adorned with leaves, lined with palm fibres, suspended 2–35 m up in palm or other tree. Clutch 1–2 eggs, very pale blue, with many red-brown spots concentrated at wider end. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Common in Liberia; uncommon or rare in rest of its geographical range. Occurs in Tai National Park, in Ivory Coast.

Bibliography. Bannerman (1948), Borrow & Demeey (2001), Bouet (1942), Chapin (1954), Cheke & Mann (2001), Fry *et al.* (2000), Gray (1986), Hall & Moreau (1970), Holman (1949), Lachenaud (2006b), Rand *et al.* (1959).

85. Superb Sunbird

Cinnyris superbus

French: Souimanga superbe

German: Prachtnektarvogel

Spanish: Suimanga Soberbio

Taxonomy. *Certhia superba* Shaw, 1811, Malembo, Cabinda, Angola.

Genus often subsumed in *Nectarinia*. Four subspecies recognized.

Subspecies and Distribution.

C. s. ashantiensis Bannerman, 1922 – Sierra Leone and S Mali E to Togo and NW Benin.

C. s. nigeriae (Rand & Traylor, 1959) – SE Benin and S Nigeria.

C. s. superbus (Shaw, 1811) – S Cameroon, Central African Republic and DRCongo (except NE) S to W Angola.

C. s. buvuma van Someren, 1932 – NE DRCongo, Uganda, W Kenya and extreme NW Tanzania.

Descriptive notes. 14–16 cm; male 13.8–14.7 g (*ashantiensis*), 17–24 g (*buvuma* and nominate), female 13.2 g (*ashantiensis*), 16–20.6 g (*buvuma* and nominate). Male nominate race has dark metallic blue-green on forehead and crown (reflecting greenish at some angles), black lores, metallic green stripe over eye, bronzy ear-coverts and cheek, metallic gold-green or blue-green upperparts; remiges and greater upperwing-coverts black, lesser and median coverts metallic green; chin metallic purple, throat and upper breast deep metallic blue (looking purple in some lights), rest of underparts dark maroon-red except for black

central and lower belly, thighs and undertail-coverts, the last with maroon tips; axillaries and underwing-coverts black; iris dark brown; bill and legs black. Female is grey-brown with olive wash above, with broad yellow-white supercilium from lores to behind dark olive ear-coverts, uppertail-coverts olive-green, wing dark brown, flight-feathers with light yellow or olive margins, except for grey-brown lesser wing-coverts, black-brown rectrices tipped pale brown (apart from

central pair); chin yellow-white, otherwise green-yellow below, with varying amounts of brown mottling on breast, undertail-coverts orange-yellow, axillaries and underwing-coverts yellow-white; iris dark brown, bill black, legs dark grey. Young male resembles female but slightly larger, occasionally with green tinge on back. Race *ashantiensis* is smaller (male wing 67–74 mm, male bill 26–29 mm) than nominate (72–83 mm, 28–33 mm), metallic cap of male smaller, not extending back to nape; *huvuma* male has upperparts darker and greener, less golden, than nominate and is darker below; *nigeriae* male is brighter red below than nominate. VOICE. Song consists of sequences of “weet-choo weet-choo witchoo witch”, “weetch-doo, weetch-doo” and variants. Calls “chip” and “sweet”.

Habitat. Mature forest and secondary forest, gallery forest, forest edge, coffee plantations, savanna, mangroves, tree nurseries, overgrown cultivations and clearings. Found in forest at up to 1400 m in Liberia and Uganda, but does not penetrate montane forest.

Food and Feeding. Nectar, seeds, including those of *Xylopia aethiopica*, fruits, also insects, spiders (Araneae) and snails. Forages generally singly and in pairs. Visits *Berlinia grandiflora*, *Bombax*, *Carica papaya*, *Citrus limon*, *Citrus sinensis*, *Coffea*, *Erythrina abyssinica*, *Erythrina indica*, *Erythrina mildbraedii*, *Markhamia*, *Musa*, *Occhthocosmus africanus*, *Spathodea* and mistletoes (Loranthaceae). Grabs chironomid midges in flight; hovers in front of flowers.

Breeding. Egg-laying recorded in Feb and Nov in Ghana, Jul in Nigeria, Feb, Jul and Oct–Nov in Cameroon, Oct–Mar in Gabon, Apr in PR Congo, Mar–May and Jul–Sept in Uganda and Dec in Angola; season probably Jul–Dec in DR Congo and breeding activity observed in Nov in Tanzania. Male displays with wings outstretched, song and fast movements. Nest built by female alone, taking a day to a month to complete the task, an untidy structure made variously of grass, fibres, strips of banana bark, leaves, *Usnea* lichens and moss, decorated with lichen or moss, loose “beard” hanging for 30–60 cm below, lined with grass, fibres, banana bark or seed down, suspended 2–10 m above ground and usually well hidden, appearing like bundle of dead grass. Clutch 1 egg, sometimes 2, glossy cream or pale blue-white with grey, dark slate or purple-black speckles and blotches, sometimes concentrated at wider end; incubation by female, but male assists in feeding of chicks; no information on duration of incubation and nestling periods. Male may start breeding activities before gaining full adult plumage.

Movements. No data.

Status and Conservation. Not globally threatened. Common in Liberia and Gabon; locally common in Angola; not uncommon in Ghana, Togo and Nigeria, and in Uganda. Occurs in several protected areas, e.g. Korup National Park, in Cameroon.

Bibliography. Baker & Baker (2007), Bannerman (1948), Borrow & Demey (2001), Bouet (1942), Carroll (1988), Chapin (1954), Cheke & Mann (2001), David & Gosselin (2002b), Friedmann & Williams (1971), Fry *et al.* (2000), Hall & Moreau (1970), Herroelen (2006), Lachenaud (2006a, 2006b), Rand & Traylor (1959), Rand *et al.* (1959), Traylor & Parelius (1967).

86. Rufous-winged Sunbird

Cinnyris rufipennis

French: Souimanga à ailes rousses **German:** Rotflügel-Nektarvogel **Spanish:** Suimanga Alirrojo

Taxonomy. *Nectarinia rufipennis* Jensen, 1983, Udzungwa Mountains, Tanzania.

Genus often subsumed in *Nectarinia*. Relationships of this species unclear. Monotypic.

Distribution. E escarpment of Udzungwa Mts, in E. Tanzania.

grey, tipped grey, underwing dark grey with pale grey underwing-coverts; iris dark brown; bill and legs black. Male non-breeding plumage has white patches on red chestband and mottling on head. Female has crown, face and nape greyish-olive and back and underwing-coverts olive-green, feathers of crown, nape, underwing-coverts and back with black centres (these areas appear mottled), lower nape to uppertail-coverts glossed turquoise, uppertail-coverts more green-tinged olive than back; uppertail black, outer edges brown with turquoise tinge and tipped white; underwing blackish-grey, remiges with red-brown outer edges, broadest on secondaries, greater wing-coverts with grey outer edges; olive-green below, paler on chin and belly, black feather centres giving streaked or spotted effect (variable), undertail black, tipped white, underwing-coverts grey; bare parts as male. Juvenile undescribed. VOICE. Male song a high-pitched trilling, accompanied by high-pitched chirping by female. Varied calls include “see-it” during foraging, loud “tyew”, trilling “tiddit”, and a “drep-drep” flight call.

Habitat. Moist montane forest with lichens, mosses and epiphytes, venturing out into glades within 20 m of forest edge. At 600–1700 m; most common at 1500–1700 m.

Food and Feeding. Nectar; probably also insects, as leaf-gleaning observed. Forages singly and in pairs; joins mixed-species flocks. Feeds 0.5–30 m from ground. Visits flowers of *Achyrosperrum carvalhi*, *Achyrosperrum radicans*, *Leucas densiflora*, *Tecoma capensis* and mistletoes (Loranthaceae).

Breeding. Juvenile being fed by female in Jan, and other breeding activity observed in Feb. Nest made of grass, rootlets and cobwebs, suspended at 5 m from shoot of *Sinarundinaria alpinum* bamboo. No other information.

Movements. Probably undertakes altitudinal movements in synchrony with availability of flowers and insects, but some resident at preferred sites.

Status and Conservation. VULNERABLE. Restricted-range species: present in Tanzania–Malawi Mountains EBA. Locally common. Has small range covering c. 3360 km² and decreasing population estimated at 10,000–19,999 individuals. Known from eight localities, all within well-protected areas: occurs in forests of Mwanibana and Iwonde, both in Udzungwa Mountains National Park, at Ukami, Ndundulu and Nymbanitu, in West Kilombero Scarp Forest Reserve, and in Katemele, Kiranzi-Kitungulu and Uzungwa Scarp Forest Reserves. Any suitable habitat in intervening, non-protected areas probably declining in extent and/or quality as a result of deforestation and forest degradation. This species’ future survival appears to be dependent on conservation of forests in its restricted geographical range.

Bibliography. Anon. (2007), Baker & Baker (2007), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar & Stuart (1985), Collar *et al.* (1994), Dinesen *et al.* (1993), Fry *et al.* (2000), Jensen (1983), Jensen & Brøgger-Jensen (1992), Stattersfield & Capper (2000), Stuart *et al.* (1987).

87. Oustalet’s Sunbird

Cinnyris oustaleti

French: Souimanga d’Oustalet **German:** Angolanektarvogel **Spanish:** Suimanga de Oustalet
Other common names: Oustalet’s White-bellied/Angola (White-bellied)/Caconda White-bellied Sunbird (*oustaleti*); Zambian Sunbird (*rhodesiae*)

Taxonomy. *Nectarinia oustaleti* Bocage, 1878, Caconda, Huila, Angola.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. talatala*; both have sometimes been considered to be part of a superspecies that also includes *C. bouvieri*, *C. oseae* and *C. asiaticus*. Two subspecies recognized.

Subspecies and Distribution.

C. o. oustaleti (Bocage, 1878) – WC Angola.

C. o. rhodesiae Benson, 1955 – NE Zambia and W & SW Tanzania.

Descriptive notes. 10–11 cm. Male nominate race breeding is iridescent green above, except for iridescent blue-green crown and iridescent blue uppertail-coverts; remiges very dark brown with paler margins; rectrices black, faintly tinged blue, webs of central pair and outer webs of T2–T5 edged iridescent blue, outermost rectrix brown, tipped white on outer web; chin and throat iridescent green-blue above two breastbands, upper one purple with some maroon at base, narrower lower one brown-black; otherwise white below, with orange-and-yellow pectoral tufts, whitish underwing-coverts and axillaries; iris dark

brown; bill and legs black. Male non-breeding (eclipse plumage) resembles female, but has pectoral tufts and metallic colours on wing-coverts and uppertail-coverts, is greyer on throat and breast, and has sparse metallic feathering on body. Female has head and upperparts dark grey-brown, with thin pale supercilium backwards from above eye, longest uppertail-coverts blacker with tips glossed greenish; remiges dark grey-olive with narrow pale buff edges; rectrices black, central two or three pairs narrowly edged metallic green, outer pair dusky white on outer web and with broad white tips on inner webs, other rectrices narrowly tipped white; greyish-buff to greyish-olive throat, breast and flanks appear streaked (as feathers have off-white fringes), rest of underparts somewhat paler and unstreaked; bare parts as male. Juvenile is dark grey-brown above, including wings, black tail with outer webs of outermost feather pair tipped dusky white, the rest except central pair narrowly tipped off-white, throat and breast grey, otherwise dusky white below, with pale yellow wash in middle of abdomen. Race *rhodesiae* is very like nominate, but bill smaller (male 17–19 mm; nominate male 19–22 mm), female has paler belly. VOICE. Song consists of ascending and descending high-pitched notes. Calls include repetitions of “cheep” and varied notes and sequences such as “chip”, “chip-chuu-chuu”, “tu-ter-twee, tu-ter-twee” with the “tu” higher-pitched, and “tzzip”.

Habitat. *Brachystegia*–*Isoberlinia* woodland, dense scrub and secondary growth.

Food and Feeding. Insects and spiders (Araneae); also, presumably, nectar. Forages singly and in small groups, often low down. Visits flowers of *Diplolophium*, *Canna*, *Nectaros* and *Parinari mohoba*.

Breeding. Egg-laying months Oct–Feb in Angola and Mar–Jun in Zambia. No other information.

Movements. Poorly known. Recorded as vagrant in N Malawi.

Status and Conservation. Not globally threatened. Locally common in Angola; rare in Zambia and Tanzania.

Bibliography. Aspinwall (1989), Baker & Baker (2007), Benson *et al.* (1971), Chapin (1954), Dillingham (1984), Dowsett-Lemaire & Dowsett (2006), Fry *et al.* (2000), Hall (1960), Hall & Moreau (1970), Moyer (1983), Williams (1955).

88. White-breasted Sunbird

Cinnyris talatala

French: Souimanga à ventre blanc

German: Weißbauch-Nektarvogel

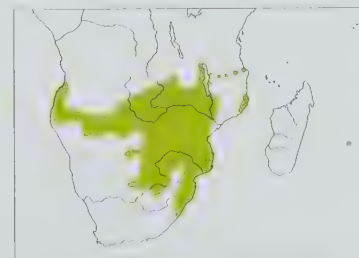

Spanish: Suimanga Pechiblanco

Other common names: (Southern) White-bellied Sunbird

Taxonomy. *Cinnyris talatala* A. Smith, 1836, between Orange River and Kurrichaine, South Africa.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. oustaleti*; both have sometimes been considered to be part of a superspecies that also includes *C. bouvieri*, *C. oseae* and *C. asiaticus*. Proposed races *anderssoni* (described from NW Namibia), *lumbo* (from Lumbo, in N Mozambique) and *arestus* (from near Eshowe, in KwaZulu-Natal) considered inadequately differentiated from birds elsewhere in species’ range. Monotypic.

Distribution. SW & S Angola and N Namibia E to Zambia, Malawi and patchily to SE Tanzania, S to N & E Botswana, Zimbabwe, Mozambique, Swaziland and E South Africa (North West and Limpopo Provinces S to N Free State and Kwazulu-Natal).

Descriptive notes. 10–12 cm; 6–4–10 g. Male breeding has head and upperparts, including median and lesser underwing-coverts, iridescent green, uppertail-coverts iridescent blue-green, remiges and primary and greater coverts brown, outer margins of remiges pale buff when fresh, rectrices green-black with green margins, outermost feather pair tipped whitish on inner web; chin and upper throat iridescent blue, lower throat reflecting green; upper breastband blue above and purple below, bordered below by black band; yellow pectoral tufts; belly normally yellow-white but sometimes grey with yellow middle, or white with yellow in centre

or completely pale yellow, flanks and undertail-coverts whitish; iris dark brown; bill and legs black. Male in supposed non-breeding plumage has wing and tail as breeding, but metallic feathers re-

stricted to middle of chin, upper breast, head, back and uppertail-coverts, otherwise as adult female (existence of this eclipse plumage in doubt, and such individuals may be subadults). Female is grey-olive or brown above, wing-coverts without iridescent green (but some are glossy on lesser wing-coverts), tail olive-black, rectrices (except outer two pairs) glossy green on outer edges, outer rectrices with outer web and tip and part of inner web white; throat and breast greyish-olive, belly yellow or off-white, undertail-coverts pale yellow-white; bare parts as male. Juvenile male is as adult female, but with black throat and hint of iridescence on forehead, shoulders and rump. Voice. Song complex and varied, often starting with up to 6 "tsk" notes, sometimes leading into melodic warble, before "tsweet-tsweet-tsi-tsi-tsi" for 2 seconds and then a trill or "weeah-weeah, tchwee-tchwee" followed by up to 18 "teli" notes; both sexes sing. Calls and songs sometimes include mimicry of Common Bulbul (*Pycnonotus barbatus*), Chestnut-vented Warbler (*Sylvia subcaerulea*), Neddicky (*Cisticola fulvicaupilla*), Rattling Cisticola (*Cisticola chiniana*), Black-chested Prinia (*Prinia flavicans*), Bronze Mannikin (*Lanius cucullata*) or Streaky-headed Seed-eater (*Serinus gularis*).

Habitat. Dry savanna woodland, *Banksia*, *Combretum*, mombi and mopane woodlands, gardens, parks and riverine forest.

Food and Feeding. Insects, such as aphids (Aphidoidea), and nectar. Forages singly, in pairs and in small, loose groups. Visits variety of flowering plants, including *Acacia sieberiana*, *Aloe arborescens*, *Banksia plurijuga*, *Bauhinia galpinii*, *Callistemon viminalis*, *Capparis tomentosa*, *Cassia singuena*, *Combretum mossambicense*, *Cordia africana*, *Dalbergia nitidula*, *Dicentra spectabilis*, *Dioscorea chrysostachya*, *Erythrina abyssinica*, *Erythrina lysistemon*, *Halleria lucida*, *Ipomoea lobata*, *Jacaranda mimosifolia*, *Leonotis leonurus*, *Rosmarinus officinalis*, *Tecoma capensis*, *Tithonia tagetiflora* and mistletoes (Loranthaceae). Hovers in front of flowers to feed, and capable of flying backwards. Drinks from birdbaths.

Breeding. Laying recorded in Sept–Oct in Zambia, Jan and Apr–Oct in Malawi, Jun–Dec in Zimbabwe, Feb–Mar in Namibia, Jan, Mar, Jul and Sept–Dec in Botswana, Feb–Aug in Mozambique, and Jul–Feb in South Africa; sometimes double-brooded. Male display involves uttering warbling song while in semi-circular flight, before returning to perch. Nest built by female, taking 4–8 days, consisting of an untidy oval structure made from grass, leaves and cobwebs, with or without porch and lining, occasionally adorned with dead leaves and other material (such as newspaper), suspended 0.2–3.2 m above ground from shrub or tree, including from exotic cactus *Cereus peruvianus*. Clutch 1–2 eggs, white with purple-grey and olive speckles concentrated at wider end or with indistinct pale fawn and light ash speckles; incubation by female, period 13–14 days; both sexes may feed chicks and remove faecal sacs, nestling period 14–15 days; fledglings return to nest to roost for up to 4 nights, and continue to be fed by female for a week.

Movements. Resident and migratory. Some apparently move from drier W & S areas of S Africa to wetter E & N areas in dry austral winter months, and may go farther W if austral summer rains above average; influxes in Zimbabwe in May–Sept, and common Feb–Jul but rare Aug–Jan at Mazabuka (Zambia). Breeding visitor Namibia, Oct–Apr. Active migration to NE observed in N Botswana in Apr.

Status and Conservation. Not globally threatened. Abundant to locally common throughout geographical range. Occurs in several protected areas, e.g. Etosha National Park, in Namibia, Lwonde National Park, in Malawi, and Mkuze Game Reserve, in South Africa.

Bibliography. Borello (1992), Buchanan & Steyn (1964), Chapin (1954), Cheke & Mann (2001), Cliney (1962, 1967a), Cole (1992), Cyrus (1989), David & Gosse (2002b), Earle (1981a, 1981b, 1981c, 1982), Fry *et al.* (2000), Hall & Moreau (1970), Hamner (1981, 1989), Herremans (1992), Hockey *et al.* (2005), Hustler (1985), Johnson & Brown (2004), Kochler *et al.* (2006), Mackworth-Praed & Grant (1948), McCarthy (2006), Medland (1992), Nicolson & Fleming (2003), Shaw (2001a), Skead (1967), Tree (1988, 1990, 1991, 1997f), Traylor (1962), Vincent (1949).

89. Variable Sunbird

Cinnyris venustus

French: Soumanga à ventre jaune. **German:** Ziernektarvogel. **Spanish:** Suimanga Variable. **Other common names:** Yellow-bellied/Yellow-breasted/Buff-breasted/Buff-chested Sunbird; White-bellied (Variable)/Somali Sunbird (*albiventris*); Orange-bellied (Variable) Sunbird (*igniventris*).

Taxonomy. *Certhia venusta* Shaw, 1799, Sierra Leone.

Genus often subsumed in *Nectarinia*. Has been thought to be closely related to, and possibly forming a superspecies with, *C. ustulata*. Other proposed races include *bliski* (described from S shore I, Stefanie, in SW Ethiopia), synonymized with *albiventris*, and *sukensis* (from R Turkwell, in N Kenya), merged with *fazoglensis*; *kunziae* (Malanje, in N Angola), *massae* (Malawi), *cymescens* (Zanzibar) and *stierlingi* (Uhehe, in S Tanzania) are all treated as synonyms of *falkensteini*. Five subspecies recognized.

Subspecies and Distribution

C. v. venustus (Shaw, 1799) = Senegal, Gambia and Sierra Leone E to Nigeria, N Cameroon and Central African Republic.

C. v. fazoglensis (Heuglin, 1873) = E Sudan, Eritrea and W Ethiopia.

C. v. albiventris (Strickland, 1852) = E & S Ethiopia, Somalia and NE Kenya.

C. v. falkensteini G. A. Fischer & Reichenow, 1884 = SE Sudan S to W & S Kenya, and from S Gabon and W Angola E to S DR Congo, Tanzania (including Pemba I and Zanzibar), Zambia, Malawi, Zimbabwe and Mozambique.

C. v. igniventris Reichenow, 1899 = E DR Congo, Uganda, Rwanda and Burundi.

Descriptive notes. 10–11 cm; 5–10 g. Male nominate race has front half of crown metallic purple, lores black, rest of crown, ear-coverts, throat, neck and upperparts, including lesser and median upperwing-coverts, metallic green, uppertail-coverts metallic blue (green in some lights); remiges and greater upperwing-coverts brown, greater coverts, primary coverts and alula finely edged metallic green when fresh, black tail edged metallic blue or green, outer two feather pairs tipped pale grey; chin and upper breast metallic purple, latter fusing with unglossy black area at lower border, otherwise pale yellow below, pectoral tufts yellow and

scarlet (sometimes only yellow), undertail-coverts white, tinged yellow, underwing-coverts white, axillaries pale yellow or white; iris dark brown; bill and legs black. Non-breeding male may retain metallic feathers on chin, throat, upper breast, lesser wing-coverts and uppertail-coverts and a few on back, otherwise resembles female but more olive-brown; some populations may lack eclipse plumage. Female is smaller than male, has crown and upperparts grey-brown, tinged olive on rump and lesser wing-coverts, wing darker, rectrices black, tinged glossy green, with whitish tips, broadest on outer pair of feathers, which also with pale outer webs; chin and throat whitish, otherwise pale yellow below, underwing-coverts and axillaries white with yellow tinge; bare parts as male. Immature male is as adult female, but throat and breast with dusky markings, appearing as dark streak on throat, and no pale tips on outer tail feathers. Race *albiventris* male has white abdomen, female grey-brown above, faint streaking on throat and breast, off-white below; *falkensteini* male is deeper yellow below than nominate, eclipse plumage (not acquired by all males) more like breeding (only 10–20% of metallic feathers lost, dusky feathers present on crown and chest), immature at end of first year acquires plumage with only 50–80% of full metallic complement, becoming fully adult after third moult (at end of second year); *fazoglensis* male resembles previous, but has metallic green, not purple-blue, on throat above purple breast; *igniventris* male differs in having orange-scarlet in centre of chest, scarlet pectoral tufts. Voice. Song consists of repetitions of a sequence of 3–4 "tsch-tsch-wee" notes followed by fast trilling of up to 15 "eh" notes, sometimes preceding high-pitched warble of rapid ascending and descending notes. Subsong of "tsrrr" trill followed by "tschi-pu". Calls include "chip-chip", "chop-tsee-tsk-tsk", "tser-tze-zip" and "tew-tew-tew"; "cheer-cheer" or "tshwee, tshwee, tshwee" alarm calls.

Habitat. Thornbush savanna, brachystegia (*Brachystegia*) woodland, forest, forest edge, wooded ravines, farmland, parks, open coastal habitats, mangroves, coconut plantations, inselbergs, montane savanna, slopes with proteas (*Protea*), also in gardens in urban areas; generally in moister and more wooded areas in S part of range. Lowlands and mountains; to 2700 m in Rwenzori Mts (DR Congo–Uganda).

Food and Feeding. Nectar, insects, and spiders (Araneae). Forages singly, in pairs and in small groups; joins mixed-species flocks. Visits variety of flowers, including those of *Acacia sieberiana*, *Acrocarpus fraxinifolius*, *Aloe*, *Albizia coriaria*, *Berlinia grandiflora*, *Callistemon citrinus*, *Combretum mozambicense*, *Erythrina humeana*, *Fourea speciosa*, *Grevillea banksii*, *Grewia similis*, *Halleria lucida*, *Hibiscus*, *Jacaranda mimosifolia*, *Kniphofia*, *Leonotis mollissima*, *Parkia filicoides*, *Protea*, *Prunus*, *Symphonia globulifera*, *Tecoma*, *Thevetia peruviana*, and mistletoes (Loranthaceae). Mistletoes include e.g. *Tapinanthus globiferus*, closed flowers of which the bird itself opens in order to reach the nectar. Gleans leaves for insects, and probes and hovers in front of flowers; catches insects on the wing. Drinks from birdbaths.

Breeding. Laying recorded in Mar in Gambia, Oct in Sierra Leone, Dec in Liberia, Jul in Togo, Oct–Jan in Nigeria, Nov–Jan Sudan, Jun in Eritrea and Apr–Oct Ethiopia, Aug–Sept in DR Congo, Feb–Mar and Sept–Oct in Uganda, all months (peaks Jan, May and Jul) in Tanzania, Apr and Jul–Oct in Zambia, Feb–Aug and Dec in Malawi, Jan–Dec in Zimbabwe and Apr–Sept in Mozambique; sometimes double-brooded. Female does bulk of nest-building, male helping occasionally, task taking 10–20 days, nest an untidy flimsy oval with porch, sometimes short "beard", made variously from grass, reeds, rootlets, fibres, flowers, leaves and cobwebs, lined with vegetable down or feathers, placed 0.9–2 m up in creeper, bush or small tree. Clutch 1–3 eggs, matt white to grey-green or grey-white, very densely speckled with ash-brown, brown, fawn, greyish or purple-grey spots, concentrated at wider end; incubation by female, period c. 2 weeks; chicks fed by both sexes, nestling period 18 days. Nests parasitized by Klaas's Cuckoo (*Chrysococcyx klaas*).

Movements. Variously resident, nomadic and migratory, but movements unclear. Ascends to higher altitudes during droughts in Zimbabwe, where one ringing recovery showed movement of 25 km. Resident on coast in Nigeria but absent in other S habitats there during Apr–Oct, when occurs in N Nigeria. Present Gabon Mar–Oct.

Status and Conservation. Not globally threatened. Common over most of its geographical range; rare in extreme S. Occurs in a number of protected areas in most parts of range.

Bibliography. 90. Dusky Sunbird

Cinnyris fuscus

French: Souimanga fuligineux **German:** Rußnektarvogel **Spanish:** Suimanga Oscuro
Other common names: White-vented Sunbird, Namaqua Sunbird

Taxonomy. *Cinnyris fuscus* Vieillot, 1819, Great Namaqualand, Namibia. Genus often subsumed in *Nectarinia*. Has been thought to form a superspecies with *C. cupreus*. Two subspecies recognized.

Subspecies and Distribution.

C. f. inclusus (Clancey, 1970) – coastal SW Angola (Benguela, and Namibe S to R Cunene).
C. f. fuscus Vieillot, 1819 – Namibia, W & C South Africa and S Botswana.

Descriptive notes. 10 cm; male 7–10 g, female 6–7 g. Male nominate race breeding has head blackish-brown with faint purple-blue iridescence, upperparts dark brown with blue, purple and bronze-green iridescent tinge; tail black slightly glossed blue above, upperwing brown, lesser and median upperwing-coverts very dark brown with green reflections; throat and breast black-brown with purple and bronze-green reflections, lower breast sooty black, pectoral tufts orange (sometimes yellowish-orange), upper belly white, lower belly and undertail-coverts whitish or buffish, axillaries and underwing-coverts dark brown; iris dark

brown; bill and legs black. Male non-breeding (eclipse plumage) lacks black plumage except on throat and from head to rump, and a few metallic feathers may remain on upperparts and lesser wing-coverts. Female has head, upperparts and upperwing dull brown, uppertail-coverts and tail very dark black-brown, throat and underparts very pale grey-olive, whitish on lower belly and undertail-coverts, underwing-coverts white, axillaries grey; bare parts as male. Juvenile is like female, but greener upperparts and tinged yellow on underparts. Race *inclusus* male has purple-tinged glossy (not matt) black area below metallic throat, and whiter flanks and undertail-coverts than nominate, lacking brown feathers. Voice. Song begins with “tst” and then a “trr-trr-trr...” trill for c. 2 seconds, changing down in tone half-way through before ending with “tschut”; trill variable, and variety of other songs noted, e.g. “sweek, week, wee-aswirrik, e.e.e.” and husky “shreep-chip, chip, chip, chip, chip, chip, chip, chip”. Calls also varied, include “tsk”, “weeh, weeh” and flight call of “ji-dit”.

Habitat. Dry country, including semi-arid coastal plains with sand dunes (but not sandy desert), acacia (*Acacia*) scrub along watercourses, inselbergs with scattered bushes, hillside scrub, also orchards and gardens.

Food and Feeding. Insects and nectar. Forages mostly in pairs, sometimes in groups; aggregations of hundreds occasionally recorded, e.g. at large patches of *Nicotiana*. Associates with other sunbirds. Food taken from such plants as *Drosanthemum luderitzii*, *Leonotis oxymifolia*, *Lycium campanulatum*, *Nicotiana glauca*, and those of genera *Acacia*, *Aloe* (of at least seven species), *Cadaba*, *Canna*, *Crassula*, *Crocosmia*, *Hibiscus*, *Lantana*, *Psilocaulon*, as well as *Tapinanthus oleifolius* and other mistletoes (Loranthaceae). Hawks for insects; hovers in front of flowers. Drinks water at pools.

Breeding. Egg-laying recorded in all months (peak Feb–Apr) in Namibia and Aug–Mar in South Africa; in years when rains begin early, males may breed when still moulting out of eclipse plumage; possibly double-brooded. Aerial courtship displays; moth-like flights during male encounters with other males. Oval nest made of grass, fibres, bark, leaves and cobwebs, adorned with wool or miscellanea such as tissue paper, lined with plant down or hair from gemsbok (*Oryx oryx*), placed low down, 0.1–1.65 m above ground, in shrub or tree, often beside watercourse. Clutch 1–3 eggs, white with a few grey-blue, purple-brown or brown blotches, mottles and spots; incubation by female, period 12–13 days; female alone broods chicks and removes faecal sacs, but both sexes feed chicks, of which only one usually survives, nesting period 13–15 days; young fed by parents for 2–3 weeks after leaving nest. Nests known to be parasitized by Klaas’s Cuckoo (*Chrysococcyx klaas*).

Movements. Nomadic in response to availability of flowering plants and droughts; may irrupt into SW Cape region of South Africa.

Status and Conservation. Not globally threatened. Locally common to very common in Angola and Namibia; rather uncommon in South Africa but locally more numerous, mainly in W of range there. Occurs in Spitskop Nature Reserve, in South Africa.

Bibliography. Cheke & Mann (2001), Clancey (1970b), Fraser & Wheeler (1991), Fry *et al.* (2000), Hall & Moreau (1970), Harrison (1997b), Hockey *et al.* (2005), Jensen & Clinning (1974), Molyneux (1976), Sked (1967), Williams *et al.* (1986).

91. Ursula’s Sunbird

Cinnyris ursulae

French: Souimanga d’Ursula **German:** Graubrust-Nektarvogel **Spanish:** Suimanga de Úrsula
Other common names: Fernando Po (Mouse-coloured) Sunbird, Ursula’s Mouse-coloured Sunbird

Taxonomy. *Cyanomitra ursulae* Alexander, 1903, Mount St Ysabel, Bioko.

Genus often subsumed in *Nectarinia*. Has been thought to be closely related to, and possibly forming a superspecies with, *C. venustus*. Monotypic.

Distribution. Mountains of SW Cameroon and Bioko I (Fernando Póo).

Descriptive notes. 9–10 cm; 5.3–7.3 g. Male has forehead and forecrown grey, tinged metallic blue, sides of face grey, hindcrown and upperparts olive-green, upperwing black-brown, edges of remiges and all upperwing-coverts yellowish, tail black-brown with olive-yellow edges; chin and throat pale brown, breast greyer, otherwise pale yellow-tinged olive below, orange-red pectoral tufts; axillaries and underwing-coverts white; iris brown; bill and legs black, toes dark grey. Female is like male, but pectoral tufts duller orange. Immature resembles adult but without pectoral tufts and metallic feathering, has chin and upper throat mottled grey and whitish, throat and upper chest dark grey-green, otherwise yellow-olive below, brightest on belly. Voice. Songs include de-

scending high-pitched trill and complex sequence with “tzip-tzip-tzip”, a whistling warble, trills, “tseep” and “weet”. Calls include “tsit-tsit”, “tche-tchu”, and bursts of accelerating and slightly falling “tseep-tseep-tseep-tseep”.

Habitat. Primary and secondary forest and forest edges in highlands. At 950–1250 m on Mt Cameroon, 950–2050 m on Mt Kupé; 1000–1200 m on Bioko, where found particularly in moss forest.

Food and Feeding. Nectar, seeds, insects, some spiders (Araneae). Forages singly and in pairs; associates with other sunbirds. Visits

flowers of *Rauvolfia vomitaria*, also those of families Flacourtiaceae and Rubiaceae; forages in shrubs on forest floor and in trees.

Breeding. Egg-laying in Jan, Mar and Dec in Cameroon. Nest a compact cushion, mostly of moss with some rootlets and cobwebs, short moss porch but no “beard”, placed low down (3.5–4.2 m) among moss-covered branches, creepers, lianas or shrub. Clutch 1–2 eggs, white, tinged chestnut; chicks fed by both parents. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Cameroon Mountains EBA. Uncommon to locally common in Cameroon, but possibly often overlooked; rare on Bioko. Appears to be dependent on largely undisturbed forest within its small range, and is potentially at risk from further forest clearance.

Bibliography. Anon. (2007f), Bannerman (1948), Borrow & Demeu (2001), Butchart & Stattersfield (2004), Cheke & Mann (2001), Fry *et al.* (2000), Hall & Moreau (1970), Pérez del Val (1996), Stattersfield & Capper (2000), Stuart & Jensen (1986).

92. Bates’s Sunbird

Cinnyris batesi

French: Souimanga de Bates **German:** Einfarb-Nektarvogel **Spanish:** Suimanga de Bates
Other common names: Bates’s Olive Sunbird

Taxonomy. *Cinnyris batesi* Ogilvie-Grant, 1908, River Ja, Cameroon, and Camma River, Gabon. Genus often subsumed in *Nectarinia*. Monotypic.

Distribution. E Liberia, Ivory Coast, Ghana, and from Nigeria and S Cameroon E to N PR Congo and Central African Republic, and S, including Bioko I (Fernando Póo), to S Gabon; also NW Angola (Cabinda), E, C & SE DR Congo and extreme NW Zambia.

Descriptive notes. 9–10 cm; 5.7–7 g. Male is dark olive above, with faint pale stripe above eye, dark brown wings edged pale yellow, black tail widely edged green-olive, outer rectrices tipped olive; paler grey-olive below, yellowish on central belly; wispy pale yellow feathers (paler, sometimes white, at base) at side of breast appear as pectoral tufts, but probably elongated axillaries or underwing-coverts; iris dark brown; bill black, pale base of lower mandible; legs black. Female is like male, but elongated underwing-coverts paler, less yellow, and sometimes all white or reduced. Juvenile is similar to adult. Voice. Song a quiet

trill followed by nasal “ts-tsp” or repetitions of “ts”. Calls include “tsk”, “weet”, “tseep” and “tsp-tsp ch-ch-chur”.

Habitat. Primary forest, forest edges and cultivations with tall trees, also clearings and secondary growth.

Food and Feeding. Nectar, berries, fruits, insects and spiders (Araneae). Forages singly and in small groups in canopy; joins mixed-species flocks. Visits flowers of *Macaranga assas* and flowers in forest canopy, where usually found on mossy branches with epiphytes.

Breeding. Laying recorded in Jul and Dec in Cameroon, Feb in DR Congo and Feb–Mar in Gabon. Nest a pouch made of pappus, leaves and cobwebs, adorned with moss, lined with cottony fluff, suspended 2–3 m above ground in bush. Clutch 1–2 eggs, matt light pink with grey-green or pinkish spots and blotches, or brown with a few deep brown or yellow-brown blotches. No other information.

Movements. No data.

Status and Conservation. Not globally threatened. Rare to uncommon in most of its range, but may be overlooked. Common in Cameroon and locally common in Equatorial Guinea and in Gabon. Densities of 30–60 birds/km² recorded in Gabon.

Bibliography. Amadon (1953), Bannerman (1948), Bates (1911), Benson & Irwin (1966), Borrow & Demeu (2001), Bouet (1942), Brosset & Erard (1986), Chapin (1954), Cheke & Mann (2001), Eisentraut (1963), Fry *et al.* (2000), Hall & Moreau (1970), Mackworth-Præd & Grant (1973), Pérez del Val (1996), Prigogine (1971, 1972), Prinzing *et al.* (1989), Williams (1958, 1959).

93. Copper Sunbird

Cinnyris cupreus

French: Souimanga cuivré **German:** Kupfernektarvogel **Spanish:** Suimanga Cobrizo
Other common names: Coppery/Copper-coloured Sunbird

Taxonomy. *Certhia cuprea* Shaw, 1811, Malembo, Cabinda, Angola.

Genus often subsumed in *Nectarinia*. Has been thought to form a superspecies with *C. fuscus*. Nominative race exhibits clinal variation in size, which increases from W to E. Described race *septentrionalis* (from Mpumu, in Uganda) is synonymized with nominate and *vaughanjonessi* (from Kasempa, in Zambia) with *chaleus*. Two subspecies recognized.

Subspecies and Distribution.

C. c. cupreus (Shaw, 1811) – SW Mauritania, Senegal, Gambia and Sierra Leone E to Cameroon, Central African Republic, S Sudan, W Ethiopia, Uganda and W Kenya (W of Rift Valley), and from Gabon and NW Angola (Cabinda) E to DR Congo (except SE) and W Tanzania.
C. c. chalcus (Hartlaub, 1862) – Angola (except Cabinda), SE DR Congo, Zambia, SW Tanzania, Malawi, NE Namibia (Caprivi Strip), N Botswana (Chobe National Park, Kasane) N Mozambique and N Zimbabwe.

Descriptive notes. 12–13 cm; male 8.4–11.4 g (*chalcus*), 6.8–8.4 g (*cupreus*, W Africa) and 7.5–11 g (*cupreus*, Kenya), female 7.3–10.2 g (*chalcus*), 5.5–8.3 g (*cupreus*, W Africa) and 7.2–8.9 g (*cupreus*, Kenya). Male nominate race breeding has head, throat and neck metallic copper with gold, red, green or black reflections; upperparts, lesser and median upperwing-coverts and breast metallic purple, greater upperwing-coverts and remiges blackish with blue gloss, tail similar but more purple; underparts below breast black with slight gloss, underwing-coverts and axillaries black; iris dark brown; bill black; legs black. Male

non-breeding (eclipse plumage) has almost no iridescence, although a few metallic feathers retained among otherwise olive upperparts, and lesser wing-coverts and uppertail-coverts have metallic purple tips; underparts yellowish, some black on belly and flanks. Female is smaller and significantly less heavy than male, lacks metallic colours, has crown and upperparts brownish-olive, darker olive-brown ear-coverts, black lores, narrow pale yellow supercilium, dark brown remiges edged olive and pale-tipped, black tail glossed dark blue and outer rectrices browner with paler ends and outer webs; underparts olive with yellow wash, axillaries pale yellow, underwing-coverts white, yellow at edges; iris dark brown, bill and legs black. Immature male is like male in eclipse plumage but without any metallic colour on lesser wing-coverts; immature female as adult. Race *chalcus* male is more green-bronze, less purple, and longer-winged than nominate, in eclipse plumage head, mantle and throat olive-green (not metallic) and metallic patch on wing-coverts and uppertail-coverts retained. **Voice.** Song of nominate race an oft-repeated sequence of c. 18 “chip” notes, speeding up into trill of up to 10 fast notes; song of *chalcus* a warble with “tsck” notes intermixed. Calls include various utterances such as “pst”, “cht-cht”, “keek”, also high-pitched “cher, cher, cher...” alarm.

Habitat. Mainly savannas; also degraded forest, woodland, swamps, mangroves, coastal thickets, cultivations, gardens and urban areas. To 2100 m in mountains.

Food and Feeding. Nectar, fruits, insects, sometimes taken in mid-air, and spiders (Araneae). Forages singly, males sometimes in groups; sometimes joins mixed-species flocks, normally if certain other sunbirds present. Visits variety of species, such as *Acacia polyacantha*, *Aloe cameronii*, *Bauhinia petersiana*, *Berlinia grandiflora*, *Brachystegia boehmii*, *Callistemon viminalis*, *Combretum mossambicum*, *Erythrina latissima*, *Jacaranda acutifolia*, *Leonotis leonurus*, *Passiflora quadrangularis*, *Prunus persica*, *Tecoma capense*, *Thunbergia lancifolia* and *Trichodesma physaloides*. Probes flowers, also often nectar-robbs from bases of flowers. Insects sometimes taken in mid-air.

Breeding. Egg-laying recorded in May–Jun and Sept–Oct in Gambia, Aug–Oct in Sierra Leone, Jun–Jul in Ghana and Togo, Aug–Oct in Nigeria, Sept–Oct in Cameroon, Jul–Aug in Sudan, Apr and Nov in Angola, Dec–Apr, Jun and Sept in DR Congo, Mar–Dec in Uganda, Mar–Jun, Aug and Dec in Tanzania, Dec–Mar and Jun in Zambia, Jan–Mar in Malawi, and Sept–Feb in Zimbabwe; sometimes double-brooded, e.g. in Nigeria. Territorial; intruders, including other bird species, aggressively repelled. Displaying male flies to above tree height, then zigzags in undulating flight, singing all the time; courtship behaviour involves leaning forwards, stretching neck, with bill held open and secondaries crossed over rump, tail twisted to one side, puffing out body feathers and shivering while calling. Nest built by female alone, pear-shaped, with grass porch and “beard”, made of grass, leaves, lichen, bark, roots, fibres, down and cobwebs, lined with roots and pappus, suspended 0.75–4.5 m up in creeper, bush or tree. Clutch 1–3 eggs, brown to light grey or pale green-white, with sepia, olive, dark brown, black, purple-brown or ash-grey blotches, spots and streaks; incubation by female or by both parents, period 2 weeks; both parents feed chicks, female removes faecal sacs and tidies nest, nestling period 11–16 days. Nests parasitized by Diederik Cuckoo (*Chrysococcyx caprius*) and Klaas’s Cuckoo (*Chrysococcyx klaas*).

Movements. Partially migratory in W Africa, where some move N into savanna during rainy season (Apr–Oct) to breed. In Malawi recorded above 475 m only in Sept–May, and present in C of country (at Lilongwe) Oct–Mar, but in S (at Nchalo) noted only in Apr–Dec. Nomadic in Zimbabwe, and ringing recoveries reveal movements of up to 43 km.

Status and Conservation. Not globally threatened. Abundant or common throughout most of range; locally common in Zambia and Malawi, and uncommon in Sudan. May breed rarely in extreme SW Mauritania (Lower R Senegal area). Occurs in a number of protected areas, such as Murchison Falls National Park, in Uganda, and Lilongwe Nature Sanctuary, in Malawi.

Bibliography. Baker & Baker (2007), Bannerman (1948, 1951), Borrow & Demei (2001), Carroll (1988), Chapin (1954), Cheke & Mann (2001), Davey & Davey (1990), Fry *et al.* (2000), Hall & Moreau (1970), Hanmer (1981, 1989), Hockey *et al.* (2005), Howells (1971), Irwin (1981a), Lynes (1938), Mackworth-Præd & Grant (1945), Mariaux & Vaucher (1991), Nikolaus (1987), Oatley (1996), Prinzing & Jackel (1986), Rand *et al.* (1959), Serle (1957), Skead (1967), Tree (1990, 1991, 1997c), Tyler *et al.* (2008), Zimmerman *et al.* (1996).

94. Purple Sunbird
Cinnyris asiaticus

French: Souimanga asiatique **German:** Purpurnektarvogel **Spanish:** Suimanga Asiático

Taxonomy. *Certhia asiatica* Latham, 1790, Gurgaon, Haryana, north India. Genus often subsumed in *Nectarinia*. Has sometimes been considered to be part of a superspecies that also includes *C. bouvieri*, *C. osea*, *C. oustaleti* and *C. talatala*. Three subspecies recognized. **Subspecies and Distribution.** *C. a. brevirostris* (Blanford, 1873) – E Arabian Peninsula (N United Arab Emirates, N & C Oman), and SE Iran, E Afghanistan, Pakistan and W India (W Rajasthan and W Gujarat). *C. a. asiaticus* (Latham, 1790) – India (except W & E), Nepal and Sri Lanka. *C. a. intermedius* (Hume, 1870) – E India (Assam S to Orissa and N Andhra Pradesh) and Bangladesh E to Myanmar, S China (S Yunnan) and Indochina. **Descriptive notes.** 10–11 cm; male 6.9–11 g, female 5–10 g. Male nominate race breeding is dark metallic blue and purple above, with uppertail black, glossed blue; metallic purplish-blue on lesser upperwing-coverts, sometimes also on margins of median and faintly on greater upperwing-coverts and remiges; dark metallic blue and purple on throat and breast, sides blue-green, belly dark purple

brevirostris has shorter bill than nominate, male greener above and often lacks reddish-brown pectoral band, female paler, juvenile whiter on flanks; *intermedius* male has more violet-purple upperparts, chin and throat than nominate, female is darker above and richer yellow below, juvenile more buffy grey below. **Voice.** Song an excited “cheewit-cheewit” rapidly repeated 2–6 times, usually by male, and warbling “swi-swi-swi-a-col-a-oli” or “sisisi-sew-sew-sew”; also “t’k’k’k’...k’k’/ché/wing!- ché/wing!- ché/wing!” and variants, sometimes interspersed with call notes. Calls include “chip”, frequent loud “chweet”, rising “sweep”, hard “zik”, upslurred “chwing” and similar; in flight a shrill chirp; loud, harsh, monotonous whistle; crackling alarm call.

Habitat. Usually around flowering shrubs and trees in dry and deciduous forests, thorn-scrub, cultivation and gardens. Lowlands, generally to 1500 m, but to 1830 m in Nepal, to 2100 m in Oman and to 2400 m in S India (Nilgiri Hills).

Food and Feeding. Small insects, and spiders (Araneae); nectar, also fruits, particularly of mistletoes (Loranthaceae) but also grapes. Forages singly, in pairs and in small to medium-sized groups; larger groups (up to 200 individuals) observed in non-breeding season. Visits flowers of aloes (*Aloe*), *Avicenna marina*, *Calotropis procera*, *Lycium*, *Prosopis cineracea*, *Prosopis juliflora* and *Maerua crassifolia*.

Breeding. Breeding in all months, chiefly in dry season; laying recorded in Jan–Jul (also nestlings and a female with enlarged ovary, both Jul) in Oman, and Apr–May in Pakistan; in India, mainly May–Aug in N (but Mar–Jun in Haryana and Feb–May in Bihar) and Nov–Aug (earlier in S) in Deccan; May–Jun in Nepal, Jan–Jun (mostly Mar–Apr, occasionally to Sept) in Sri Lanka, and Feb–May in Myanmar; nest with young in Cambodia, Feb; often double-brooded in Oman and C India, and at two or more broods in quick succession in Bihar. Nest, built in 5–15 days, an oblong purse, usually with porch, made of soft grass and fibres, leaves, cobwebs, etc., decorated with detritus and rubbish, including pieces of bark and caterpillar frass, lined with silky-white seed down; suspended on twig 2–6 m (rarely, 13 m) from ground, often from inner branch of bush (including *Opuntia*), or may be hung from trelliswork, creepers, rope, chain, rafter or electric wire (including wire attached to live bulb) on verandah or even inside building, or placed among spider nest mass. Clutch 1–3 eggs, greyish-white, chocolate-brown streaks forming band around broad end; incubation period 14–15 days; nestling period 13–17 days. Nests parasitized by Plaintive Cuckoo (*Cacomantis merulinus*).

Movements. Mostly resident. Wanders to S Oman in non-breeding season, when moves in search of flowers; flocks of up to 200 seen in Jan; seen in flight over deserts 30 km from nearest suitable habitat. Recently recorded in Kuwait, Jan–Feb 2008, during very cold weather; status uncertain.

Status and Conservation. Not globally threatened. Common in Indian Subcontinent and N Oman. Expanding in United Arab Emirates in response to afforestation, which provides new nesting habitats. Occurs in many protected areas, such as Keoladeo and Nagarhole National Parks, in India, Chitwan National Park, in Nepal, and Doi Inthanon National Park, in Thailand. This sunbird’s habit of eating grapes has afforded it the status of a pest species in parts of India (Haryana and around Hyderabad).

95. Olive-backed Sunbird
Cinnyris jugularis

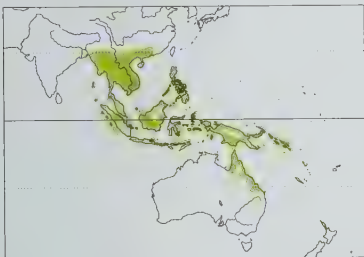

French: Souimanga à dos vert **Spanish:** Suimanga Dorsioliva
German: Grünrücken-Nektarvogel
Other common names: Yellow-breasted Sunbird (*frenatus*, *flavigaster*); Yellow-bellied Sunbird (“nominate group”); Black-breasted/Black-throated Sunbird (*idenburgi*)

Taxonomy. *Certhia jugularis* Linnaeus, 1766, Philippine Islands. Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. buettikoferi*, and possibly conspecific; closely related also to *C. solaris*, but considerable overlap in range. Races fall within two (sometimes treated in three) groups: “nominate group”, comprising populations from Continental Asia, Greater and Lesser Sundas, Sulawesi, parts of Moluccas, and Philippines S to New Guinea, Bismarck Archipelago, Solomon Is and Australia, and “*clementiae* group”, with remaining races (*buruensis*, *clementiae*, *keiensis*, *idenburgi*, *teysmanni*) from some small islands of Lesser Sundas, Moluccas and R Mamberamo region of N New Guinea. These groups may represent two separate species; moreover, the second group could arguably be split into three species, *teysmanni* and *idenburgi* each being accorded species rank and *clementiae* (with *buruensis* and *keiensis*) treated as an additional species. Alternatively, if all are deemed to belong to one species, *teysmanni* could be separated into a group of its own. It is possible that tendency for development of dark plumage is dependent on gene pool of colonizing population, and that *clementiae* (with *buruensis* and *keiensis*) descended from one “typical” race, *idenburgi* from another, and *teysmanni* from a third. It is not known if ranges of the two New Guinea races (*frenatus*, in “nominate group”, and *idenburgi*, in “*clementiae* group”) are contiguous, although a female of former and a male of latter have apparently been found together at Aiome, in R Ramu drainage (in NE part of island). Birds on Andaman is currently placed in race *andamanicus*, but some variation exists, indicating that perhaps more than one race is involved. Conversely, several races poorly differentiated, e.g. *blanfordi* could perhaps be included in *klossi* or *ornatus*, and *robustirostris* in *frenatus*. Race name *pictus*, described from NW Basilan (in W Philippines), was based on a composite specimen, major parts deriving from nominate race. Many additional races have been described, all considered insuffi-

ciently distinct to warrant retention: *tamdaoensis* (from NE Vietnam) treated as synonym of *rhizophorae*, and *annamensis* (Nha Trang, in C Vietnam) included in *flammaxillaris*; *heliobletus* (Tanjung Dungun, in Peninsular Malaysia), *microleucus* (Pulo Taya, off SE Sumatra), *helioretetus* (Tanjung Rengsam, on Bangka I, off SE Sumatra), *zapezus* (Pulo Subi, in Natuna Is), *heliomanis* (Salintukan, in E Borneo) and *pectoralis* (Java) all synonymized with *ornatus*; in Philippines, *dinagatensis* (from Dinagat) and *mindanensis* (Zamboanga, in W Mindanao) both included in nominate; *meyeri* (N Sulawesi), *dissentiens* (Indralaman, in S Sulawesi) and *saleyerensis* (Salayer I, off SW Sulawesi) all merged with *plateni*; *zenobius* (Ambon, in S Moluccas) considered inseparable from *clementiae*; and *hachisuka* (Obi, S of Halmahera), *valia* (Goodenough I, off SE New Guinea) and, in Australia, *macgillivrayi* (Cape York, in N Queensland), *olivet* (Cairns, in NE Queensland) and *australis* (Port Molle = Airlie Beach, Whitsundays, in E Queensland) all merged with *frenatus*. Twenty-two subspecies currently recognized.

Subspecies and Distribution.

C. j. flammaxillaris (Blyth, 1845) – Myanmar, Thailand, Indochina (except N) and N Peninsular Malaysia (S to Penang and Kuantan); probably W to SE Bangladesh.
C. j. rhizophorae (Swinhoe, 1869) – S China (S Yunnan, Guanxi, Guangdong, Hainan I) and N Vietnam.
C. j. andamanicus (Hume, 1873) – Andaman Is.
C. j. proselius Oberholser, 1923 – N Nicobar Is (Car Nicobar).
C. j. blanfordi (Stuart Baker, 1921) – Katchal and Kondol (Nicobars).
C. j. klossi (Richmond, 1902) – Nicobar Is (except Car Nicobar, Katchal and Kondol).
C. j. ornatus Lesson, 1827 – C & S Malay Peninsula (S of Penang and Kuantan), Sumatra and most satellites, Borneo, Java, Bali and Lesser Sundas (except Sumba, Timor and some small islands), probably also Tanimbar Is.
C. j. polyclystus Oberholser, 1912 – Enggano I, off W Sumatra.
C. j. obscurior Ogilvie-Grant, 1894 – N Philippines (N Luzon).
C. j. jugularis (Linnaeus, 1766) – Philippine Is (except N Luzon, SW and Sulu Is).
C. j. aurora (Tweeddale, 1878) – SW Philippines (Calautit, Busuanga, Culion, Dumaran, Palawan, Ursula, Balabac, Lumbacan), including islands in N Sulu Sea (Agutaya, Cuyo, Cagayancillo).
C. j. woodi (Mearns, 1909) – Sulu Archipelago (Balukbaluk, Jolo, Dammaj, Simaluc, Siasi, Tawi-Tawi, Sanga Sanga, Bongao, Papahag, Simunul, Manuk Manka, Sitanki, Omapoy, Sibutu, Tumindao, Saluag, Tres Islas), in S Philippines.
C. j. plateni (A. W. H. Blasius, 1885) – Talaud Is, Sangihe I, Siau I, and Sulawesi (including Manadotua, Manterawu, Bangka, Togian Is and Salayar).
C. j. robustirostris (Mees, 1964) – Banggai Archipelago and Sula Is (off E Sulawesi).
C. j. infrenatus E. J. O. Hartert, 1903 – Butung, Hoga I and Tukangbesi Is, off SE Sulawesi.
C. j. teysmanni Büttikofer, 1893 – islands in Flores Sea (Tanahjampea, Kalao, Bonerate, Kalaotoa and Madu).
C. j. frenatus (S. Müller, 1843) – N Moluccas (Morotai, Halmahera, Ternate, Mare, Moti, Kayoa, Bacan, Obi and Gomumu, possibly also Bisa) E to New Guinea (except N coastal region), Aru Is, D'Entrecasteaux Archipelago and NE Australia (N & E Queensland).
C. j. buruensis E. J. O. Hartert, 1910 – Buru, in S Moluccas.
C. j. clementiae Lesson, 1827 – Boano, Seram, Ambon, Saparua, Nusa Laut and Watubela Is.
C. j. keiensis Stresemann, 1913 – Kai Is.
C. j. idenburgi Rand, 1940 – N New Guinea (R Mamberano system E to R Ramu drainage).
C. j. flavigastra (Gould, 1843) – Bismarck Archipelago and Solomon Is.

ers, white-tipped black tail, and deep yellow below, slightly paler on undertail-coverts; bare parts as male. Juvenile resembles female, but usually paler and browner. Races differ to varying degrees, sometimes considerably, in plumage: *obscurior* male is paler below than nominate, and usually has brown border between throat and breast; *aurora* male differs from nominate in having variably sized bright orange band or spot on breast; *woodi* differs from last in having centre of throat metallic purple-blue; *ornatus* male differs from nominate in having variable amount of purple-black gloss on forehead and is paler yellow below (also, birds on Singapore larger); *polyclystus* male resembles previous but is much larger and has longer bill, is much darker olive above and darker yellow on posterior underparts; *andamanicus* male is browner above than preceding races, lacks metallic colour on forehead, has blue-green tinge in metallic colour of breast, a rusty breastband, bright yellow pectoral tufts (duller on slightly larger and brighter yellow-bellied birds on Narcondam, which have breastband more ginger, as do those on Coco Is, in far N Andamans), female paler and duller; *proselius* has much brighter green upperparts and less bright underparts than last, centre of throat metallic purple, forecrown usually metallic purple-blue, throat and breast metallic purple-blue (little or no maroon or chestnut on breast), rich yellow belly, pectoral tufts more orange; *klossi* is larger and bigger-billed than last, male pectoral tufts less orange; *blanfordi* male differs from previous in having little gloss on bronze-purple centre of throat and breast, more blue (less purple) gloss on breastband, less gloss on crown, and brown on face and hindcrown; *flammaxillaris* male has upperparts, including side of head and forehead, greenish olive, brown wings with green edging on remiges, blackish tail with slight blue gloss, chin and throat glossed blue at side and purple in centre, upper breast glossed purple and bordered below by maroon band, lower breast and belly yellow, greyer flanks, pectoral tufts orange, female has slight bluish gloss on black tail; *rhizophorae* male differs from preceding race in having bluish gloss on forecrown (variable, often absent), broad sooty band below maroon breastband, rest of underparts greyish-white, more yellow on centre of belly, pectoral tufts yellow; *flavigaster* male is brighter and more yellow-green above than *ornatus*, throat to upper breast glossed purple, blackish tail with slight purple gloss, short line behind eye and moustachial stripe yellow, bright yellow below with orange-yellow pectoral tufts, female similar to male above and very bright yellow below, has yellow moustachial stripe; *frenatus* male differs from last in having more extensive metallic gloss on breast in most individuals, and has more obvious yellow moustachial stripe; *robustirostris* is similar to previous but longer-billed; *plateni* is also similar, but male duller above and lacks gloss on front of face, also has yellow supercilium, purple-blue gloss on black throat, yellow moustachial stripe; *infrenatus* male differs from last in being generally darker, and lacking superciliary and moustachial stripes; *clementiae* male is yellowish-olive above, with no face stripes, has purplish throat, black abdomen and yellow

pectoral tufts, female slightly paler than *frenatus*; *keiensis* male is somewhat similar to previous but golden-green above, has slight maroon margin to purplish throat, flanks yellowish-green, orange-yellow or yellow pectoral tufts, rest of underparts blackish with purple-maroon tinge; *buruensis* male differs from last mainly in being brighter green above and lacking maroon below; *idenburgi* male is dark olive-green above, and black, glossed blue-green, below; *teysmanni* male is brownish above, has dark purple or purple-green throat, green at sides and bordered below with dark chestnut or maroon band, rest of underparts black with purple gloss, pectoral tufts orange and yellow, female has greyish-yellow supercilium and is greyish-olive above and pale yellow to yellowish-white below. Voice. Much geographical variation. Songs include discordant jumble of twittering notes; musical “cheep, cheep, chee-weet”, and short melody ending in clear trill, “tswi-tswit-titititit, tswi-tswit-tswit-tswit-tswit, tuiit tuiit-tuiit, tuchi-tuchi-tuchi-tuchi”. Other vocalizations include a loud rising “tweet”, a long loud “tsip” sometimes mixed with higher-pitched rapid twitters, a thin “sweet-sweet”, a “twe-ez”; also thin, nasal, upslurred, occasionally wavering “sweet”, and repeated “chip” note; incessantly repeated “pease” given eight times on descending scale by courting male; long wheezy “ja-zyew, ja-zyew” series; loud, piercing, upslurred “weest” (Myanmar), said to be richer and more strident than similar calls of *C. asiaticus* and *Leptocoma sperata*; loud, sharp “tsip, tsip...”, irregular or in long series (Great Nicobar), and wheezy, insistent “jha-zyew, jha-zyew...” (Katchal, in C Nicobars); flight call short “chup-chup-chup”, or “trik trik trik” similar to call of flowerpecker (Dicaeidae); persistent “sweep” by female.

Habitat. Various forest types, including mangroves, at forest edge, in open country, scrub, coastal vegetation, agricultural land, plantations, parks and gardens; found in urban areas, as well as in rural ones. Generally in lowlands, but to 1700 m.

Food and Feeding. Insects, usually small ones, and spiders (Araneae), also nectar and small fruits. Forages singly, in pairs and in small groups; joins mixed-species flocks. Generally feeds at low levels. Hover-gleans for insects, and takes spiders while hovering in front of webs; nectar-robbs flowers.

Breeding. Breeds in all months except Oct and Dec (mostly Jan–Aug) in Borneo and Java, and in all months (chiefly Oct–Mar, when less rain) in Australia; elsewhere, laying recorded in Jan–Aug and Oct in Andamans and Jan and Mar in Nicobars, in Jan–Mar, Jun–Sept and Nov in Myanmar, Jan–May, Jul–Sept and Nov–Dec in Thailand, and calculated as Dec–Jul (nest-building seen Jan–May and Jul) in Malay Peninsula; lays May and Jun in Philippines, Jan and Feb (and fledglings Dec–Sept) in Sulawesi but probably breeds throughout year in S (peak Aug–Sept on Butung and Hoga), eggs in Sept (Seram) and fledglings in Nov (Buru) in Moluccas, and laying Mar–Jul (peak Apr–May) in Lesser Sundas (Flores) and Nov in S New Guinea; often multi-brooded. Nest, built entirely by female, a pendulous oval purse 30–60 cm long, with hooded side entrance, usually with dangling “beard”, constructed from grass, cotton, bark, cocoons, moss, lichens, leaf fragments, vegetable fibres and spider webs, lined with bark or feathers, normally 0.5–1.5 m (occasionally up to 10 m) above ground, may be placed in spiny bush or suspended from palm frond, creepers, cable or fence wire, or roof or other part of house. Clutch 1–3 eggs, matt or faintly glossed, very variable, grey-green or pale grey-white to pale brown, mottled with brown overall or at broad end, or speckled black; incubation by female, period 11–16 days; chicks tended by both parents, nesting period 13–16 days. Nests parasitized in Australia by Little Bronze-cuckoo (*Chrysococcyx minutillus*). Although clutch in Borneo normally 2 eggs, usually only one chick fledges; nest predators include monitor lizards (*Varanus*) and possibly rats (*Rattus*) and ground squirrels (Sciuridae).

Movements. Resident, with short local movements. Seasonal movements in N Queensland.

Status and Conservation. Not globally threatened. Generally common throughout range. Recent sight records (presumably of race *flammaxillaris*) from SE Bangladesh almost certainly valid, but corroboration required. Attempted colonization of Booby I, in Torres Strait, presumably from near-est occupied island, 24 km distant. Occurs in numerous protected areas.

96. Apricot-breasted Sunbird

Cinnyris buettikoferi

French: Souimanga de Sumba **German:** Sumbanektarvogel **Spanish:** Suimanga de Sumba
Other common names: Sumba (Island) Sunbird

Taxonomy. *Cinnyris buettikoferi* E. J. O. Hartert, 1896, Sumba Island, Lesser Sunda Islands.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. jugularis*, and possibly conspecific; closely related also to *C. solaris*. Monotypic.

Distribution. Sumba, in C Lesser Sunda Is.

wee-chew, wee-chew-wee” (4–9 notes) repeated. Flight call sharp, high “chee” or “sip”.

Habitat. At forest edge, in secondary forest, cultivation and scrub; sea-level to at least 950 m.

Food and Feeding. No information on diet. Forages singly and in pairs, mostly in middle and upper storeys.

Breeding. No information.

Movements. None recorded.

Descriptive notes. 11 cm. Male has crown grey-brown, neck and back brown with strong olive tinge, remiges brown, edged green, tail blackish, slightly glossed, with brown tips; chin to upper breast iridescent purplish blue-green, orange breast patch, bright yellow pectoral tufts, rest of underparts yellow, white underwing-coverts; iris dark brown; bill black; legs blackish. Female differs from male in having whole underside yellow, paler on throat, with greenish-olive side of breast, and bill dark brown. Juvenile undescribed. **VOICE.** Song a long, sweet, high-pitched tinkling warble; another song consists of “wee-chew, wee-chew,

Status and Conservation. Not globally threatened. Restricted-range species: present in Sumba EBA. Very poorly known: considered very common.

Bibliography. Cheke & Mann (2001), Coates & Bishop (1997), Jones, Juhaeni *et al.* (1994), Jones, Linsley & Marsden (1995), Linsley *et al.* (1999), Rensch (1931b), White & Bruce (1986).

97. Flame-breasted Sunbird

Cinnyris solaris

French: Souimanga de Timor **German:** Sonnennektarvogel **Spanish:** Suimanga de Timor
Other common names: Timor/Sunda Sunbird

Taxonomy. *Nectarinia solaris* Temminck, 1825, Ambon; error = Timor.

Genus often subsumed in *Nectarinia*. Closely related to *C. jugularis* and *C. buettikoferi*. Described race *degener* (from Flores) considered inseparable from nominate. Birds on Atauro I (between Wetar and Timor) of uncertain racial identity, provisionally placed in nominate. Moreover, plumage variation clinal, male duldest in W of range (Sumbawa and Flores), grading through C (Lomblen and Alor) and becoming brighter in E (Semau and Timor), and most richly coloured on Wetar, where female also brightest. Race *exquisitus* rather poorly differentiated, could be considered to represent E end of cline, and species perhaps better treated as monotypic. Two subspecies tentatively recognized.

Subspecies and Distribution.

C. s. solaris (Temminck, 1825) – Lesser Sundas (Sumbawa, Komodo, Flores, Lomblen, Alor, Atauro, Timor, Semau, Roti).

C. s. exquisitus E. J. O. Hartert, 1904 – Wetar I.

Descriptive notes. 11.0 cm. Male nominate race has metallic blue-green forehead and crown, and from moustachial area and chin to upper breast, central throat purple, forming contrasting stripe; nape, ear-coverts and upperparts dull green to golden, upperwing and tail dark brown, former edged green, latter with slight bluish-black gloss, terminal third of outer tail feathers grey, tips of inner rectrices (T2 and T3) greyish; breast orange-red, pectoral tufts orange or deep yellow; abdomen orange or yellow, flanks more greenish-yellow, underwing-coverts whitish; iris blackish-brown;

bill and legs blackish. Female is greenish above, with yellow supercilium pronounced on some, lacking on others, wing brown, edged green, tail blackish with slight green gloss, terminal half of outer tail feathers white and large whitish tips on second feathers; throat and underparts sulphur-yellow to bright yellow, deeper on lower breast and belly. Juvenile resembles female, but greyer above and below, with yellow confined to side of neck, flanks and belly, and underwing-coverts yellowish-white. Race *exquisitus* male has orange-yellow pectoral tufts, heavier bill, female bright yellow below. **VOICE.** Song 1 second in duration, consists of 3–4 high-pitched, halting notes, up and down scale, with half-second interval between repetitions.

Habitat. Secondary forest, at forest edge, in woodland, scrub, plantations, *Eucalyptus alba* savanna, cultivation and gardens. Lowlands; occurs to at least 800 m on Atauro I.

Food and Feeding. No details of diet. Forages singly, in pairs and in small groups. Feeds at flowering *Tamarindus* trees.

Breeding. Laying in Mar–Aug (peak May) on Flores. Nest a rather untidy pendulous bag 14–15 × 6 cm, with entrance hole 5 cm from bottom, and lacking “tail”, constructed from various leaves and leaf fragments (some quite large) and plant fibres, suspended by a short broad connection from thorny twig. Clutch 1–2 eggs, purple-brown with darker markings (similar to those of *C. jugularis* but darker, and more purple-brown). No further information.

Movements. Nothing known.

Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Nusa Tenggara EBA and in Timor and Wetar EBA. Varies from scarce to abundant depending on island.

Bibliography. Bishop (1992), Bruce (1986), Cheke & Mann (2001), Coates & Bishop (1997), Hartert (1904), Mayr (1944a), Mees (2006), Rensch (1929, 1931a), White & Bruce (1986).

 cm 5

98. Souimanga Sunbird

Cinnyris sovimanga

French: Souimanga malgache **German:** Malegassenektarvogel **Spanish:** Suimanga Malgache
Other common names: Madagascan Sunbird

Taxonomy. *Certhia sovimanga* J. F. Gmelin, 1788, Madagascar.
Genus often subsumed in *Nectarinia*. Species name sometimes spelled “*souimanga*”, but this appears to be an unjustified emendation. Forms a superspecies with *C. humbloti* and *C. comorensis*, and all three could perhaps be considered conspecific. Mitochondrial DNA work suggests that *C. comorensis* belongs in present species, which forms a clade with *C. humbloti*, *C. coquerellii* and *C. dussumieri*, and further suggestion is that this clade colonized Indian Ocean islands from continental Africa (at earliest 3·9 million years ago) initially through Comoros; sister-group appears to contain *C. bouvieri*, *C. talatala* and *C. venustus*. Geographical variation well marked. Race *apolis* intergrades with nominate in S Madagascar (Petriky region). Five subspecies recognized.

Subspecies and Distribution.

- C. s. aldabrensis* Ridgway, 1894 – Aldabra I.
- C. s. abbotti* Ridgway, 1894 – Assumption I, in Aldabra Is.
- C. s. buchenorum* J. G. Williams, 1953 – E Aldabra Is (Cosmoledo, Astove).
- C. s. sovimanga* (J. F. Gmelin, 1788) – Madagascar (except SW) and Is Glorieuses.
- C. s. apolis* E. J. O. Hartert, 1920 – SW Madagascar (E to Ankapoky).

Descriptive notes. 10–11 cm; male 5·5–8·5 g, female 5·5–7·6 g. Male nominate race breeding has crown to mantle, upper back and lesser upperwing-coverts glossed dark green, lower back and rump dark olive-grey, tail dark brown with slight dark green gloss, upperwing dark brown, remiges edged green; throat to upper breast glossed green with glossy blue lower border, dark brownish-red band of variable width below this, rest of breast sooty brown (birds on Is Glorieuses have slightly broader breastband than nominate and narrower dark area on abdomen); pectoral tufts yellow, belly variably yellow to off-whitish, often more yellowish.

low or creamy white in centre, rest of underparts mixed yellow and grey, sometimes greenish on flanks, with dark streaking on vent; iris brown; bill and legs black. Male non-breeding (eclipse plumage) variable, may have many metallic feathers on head and breast or almost completely lack metallic feathering, and has occasional scattered red feather on chest. Female is dark olive-brown above, with pale short supercilium from just in front of eye; throat to breast greyish with dark feather fringes (giving variable scaled effect), centre of belly yellow, rest of underparts dull yellow, greyer and indistinctly streaked on sides, whiter with more distinct dark brown streaks on undertail-coverts; bare parts as male. Juvenile is as female, but without scaling on throat, and with belly and flanks much greyer, lacking yellow. Races differ mainly in colour of lower breast and belly of male: *buchenorum* male has broader red breastband than nominate, and rest of underparts except pectoral tufts dark sooty brown (males on Astove have paler smoky olive-grey flanks and lower belly than those on Cosmoledo), rump glossy green, female much darker on throat and breast than nominate; *abbotti* male differs from previous in having brown underparts and greenish flanks; *aldabrensis* male has much broader red breastband than nominate, rest of underparts sooty brown, female darker than nominate; *apolis* male differs from nominate in having centre of belly creamy white with little yellow, breastband darker and redder, underparts below sooty band off-white, female is greyer, less olive, above and paler below. **Voice.** Apparent song of short warbling phrases, with or without harsher notes. Calls include loud chirps, e.g. “pit”, repeated up to four times; “teeee, teeteeteete”, first note plaintive and diminishing, second one frequently repeated; also “chissik”.

Habitat. Forests, including mangroves, spiny subdesert vegetation, secondary growth, plantations, gardens; lowlands to 2300 m.

Food and Feeding. Insects, including beetles (Coleoptera), Hymenoptera, bugs (Hemiptera) and Orthoptera; also spiders (Araneae) and other small arthropods; nematodes; nectar. Forages in pairs; outside breeding season often in small groups, and joins mixed-species flocks. Gleans items from leaves; hovers to take items from spider webs. Pierces flower buds.

Breeding. In Madagascar, breeds from start of rains (in Oct) until Mar in NW and Jan in SE (where also fledglings Sept–Nov), but begins Jul or Aug (towards end of rains) in E; Aug–Mar (also enlarged gonads in Jun) on Aldabra, juveniles in Apr on Cosmoledo, and nesting recorded Jan on Is Glorieuses. Small oval nest well camouflaged, with small porch over entrance one-third from top, constructed from plant down, dry leaves, feathers, hair, bark and lichens, lichens used also as decoration, suspended from building, from coral overhang, from exposed roots along road cutting, in bush or from outer branch of tree c. 0·5–2·5 m above ground, occasionally over water in mangroves. Clutch 1–3 eggs, usually 2, pale greyish-white to brownish-grey, speckled brownish-grey, especially at larger end; incubation period 14 days; chicks brooded and fed by female, no information on duration of nestling period; male occasionally feeds female on nest.

Movements. None recorded.

Status and Conservation. Not globally threatened. Abundant throughout almost whole of Madagascar. Apparently very numerous also on islands elsewhere in range.

Bibliography. Benson (1984), Benson & Penny (1971), Benson *et al.* (1975), Cheke & Mann (2001), David & Gosselin (2002b), Frith (1977), Goodman & Parillo (1997), Goodman & Putnam (1997), Goodman *et al.* (1997), Hartlaub (1877), Langrand (1990), Louette (1988), Milon (1949), Penny (1974), Prys-Jones & Diamond (1984), Roberts (1987), Sinclair & Langrand (1998), Warren *et al.* (2003), Williams (1953b).

99. Humblot’s Sunbird

Cinnyris humbloti

French: Souimanga de Humblot **Spanish:** Suimanga de Humblot
German: Schlichtmantel-Nektarvogel

Taxonomy. *Cinnyris humbloti* A. Milne-Edwards and Oustalet, 1885, Grand Comoro, Comoro Islands.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. sovimanga* and *C. comorensis*, and all three could perhaps be considered conspecific. Mitochondrial DNA work suggests that these three form a clade with *C. coquerellii* and *C. dussumieri*, and further suggestion is that this clade colonized Indian Ocean islands from continental Africa (at earliest 3·9 million years ago) initially through Comoros; sister-group appears to contain *C. bouvieri*, *C. talatala* and *C. venustus*. Two subspecies recognized.

Subspecies and Distribution.

- C. h. humbloti* A. Milne-Edwards & Oustalet, 1885 – Grand Comoro, in Comoro Is.
- C. h. mohelicus* Stresemann & Grote, 1926 – Mohéli, in Comoro Is.

Descriptive notes. 11 cm; male 5·5–7 g, female 5·5–8 g. Male nominate race has crown, shoulder (often), and throat to upper breast glossed green, bordered by narrow glossy purple band; hindcrown has some glossy purple, upperparts golden-olive, with more golden wash on mantle; upperwing dark brown, edged green, tail blackish with slight green gloss, narrowly tipped grey; broad dull red band across breast, grading into yellow-olive belly and vent, pectoral tufts yellow, underwing-coverts yellowish-white; iris dark brown; bill black, legs black, soles grey. Female is olive-green above, with tail as male, otherwise

upperparts without gloss; throat to upper belly greyish, feathers with dark centres (giving scaled or speckled effect), rest of underparts yellowish with fine dark streaking, becoming unmarked buffy white on vent, some having golden wash on belly; no pectoral tufts; bare parts as male. Juvenile male is blackish above, more glossy on head and back, brown on lower breast to belly, becoming greyer and paler on flanks and towards vent. Race *mohelicus* is slightly smaller than nominate, male duller green above, lacking golden wash, has bronze-purple gloss on head and throat to breast, purple lower border of breast, more extensive glossy purple area on shoulder and larger grey tips on rectrices, female duller above than nominate, juvenile male resembles adult female but has a few metallic violet feathers on forehead and crown, maroon patches on side of chest and dark olive-green on side of belly. **Voice.** Song a jumbled series of chipping notes. Harsh scolds, “tsk, tsk”.

Habitat. Forest, scrub and gardens; sea-level to 790 m.

Food and Feeding. Insects and their larvae, spiders (Araneae), nectar and other plant material. Feeds by gleaning and hover-gleaning.

Breeding. Eggs and nestlings found in Sept, and food-carrying adults in Feb; birds with active gonads in Aug–Sept. Nest constructed from fine grass, with or without covering of moss or a few strands of *Usnea barbata* on outside, lined with soft silken pappus from asclepiads and a few feathers; average height 13 cm, maximum width 8 cm, side entrance (2 cm across) about equidistant from top and bottom, 2–5 m above ground and attached by moss to slender horizontal branch of *Philippia* bush or palm. Clutch 1 egg, rather pointed for a sunbird, whitish-grey or very faintly tinged blue or cream, finely spotted and speckled all over with pale yellow-brown on underlying pale lilac-grey (zone of concentration around top), all markings rather faint and grey underlying markings scarcely distinguishable. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Restricted-range species: present in Comoro Islands EBA. Common within small global range.

Bibliography. Benson (1960, 1970), Cheke, A.S. & Diamond (1986), Cheke, R.A. & Mann (2001), Louette (1988), Sinclair & Langrand (1998), Warren *et al.* (2003).

100. Anjouan Sunbird

Cinnyris comorensis

French: Souimanga d’Anjouan **German:** Anjouannektarvogel **Spanish:** Suimanga de Anjuán

Taxonomy. *Cinnyris comorensis* W. K. H. Peters, 1864, Anjouan, Comoro Islands.

Genus often subsumed in *Nectarinia*. Forms a superspecies with *C. sovimanga* and *C. humbloti*, and all three could perhaps be considered conspecific. Mitochondrial DNA work suggests that these three form a clade with *C. coquerellii* and *C. dussumieri*, and further suggestion is that this clade colonized Indian Ocean islands from continental Africa (at earliest 3·9 million years ago) initially through Comoros; sister-group appears to contain *C. bouvieri*, *C. talatala* and *C. venustus*. Monotypic.

Distribution. Anjouan, in Comoro Is.

Descriptive notes. 10 cm; male 7·3–9 g, female 6·8–7·5 g. Male has crown to upper back, throat to upper breast, and lesser and median upperwing-coverts glossy blue-green, lower back, rump and tail blackish with slight dark blue gloss, upperwing blackish-brown; narrow, very dark maroon band across breast; pectoral tufts orange or vermillion with yellow feather bases; rest of underparts sooty brown; iris dark brown; bill blackish; legs black with grey soles. Female is greenish-olive above, with darker mottling on crown, tail blackish with slight blue gloss, distal half of outer rectrices greyish-white, next pair with large grey distal spots;

greyish on throat, becoming yellowish on lower breast and belly, dark feather centres giving mottled appearance to throat and breast and streaking on belly; undertail-coverts buffy white; bare parts as male. Juvenile is similar to female but lacks mottling, has centre of throat and upper breast darker (one specimen much browner above); presumed juvenile male as adult female above, but with sooty chin, dark grey-green throat and upper breast, dark yellow rest of underparts with indistinct dark grey-green streaking, olive-grey flanks, dark brown bill with pale flesh-coloured base. **Voice.** Song a variable jumbled series of notes. Calls include sharp “pit pit”; “tweedle-di-dii” by female near nest, answered with sharp chirp by male; rising plaintive chirp by female; “cheep”

from birds near nest; alarm "tswi" given about eight times, rising in pitch, male slightly deeper and less shrill; also "sweet tswee, tswee, tswee, tswee" by male.

Habitat. Forest and thickets, at 90–855 m.

Food and Feeding. Diet insects, spiders (Araneae) and plant material. Few other details available. **Breeding.** Juveniles seen in Sept and birds with active gonads in Sept–Oct. Nest constructed from very fine grass, covered on outside with coarser grass and tendrils, decorated with very fine strips of curly bark and a little black fern fibre, lined with very soft asclepiad pappus, suspended by numerous fine strips of bark c. 1 mm wide (woven into top of nest) from horizontal branch of acacia bush (*Acacia*) 2 m above ground. Clutch 1 egg, white, faintly tinged bluish or greenish, boldly but not very thickly freckled all over with dull brown on underlying grey. No other information available.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Restricted-range species: present in Comoro Islands EBA. Common throughout the island.

Bibliography. Benson (1960, 1970), Cheke & Mann (2001), Hartlaub (1877), Louette (1988), Sinclair & Langrand (1998), Warren *et al.* (2003).

101. Mayotte Sunbird

Cinnyris coquerellii

French: Souimanga de Mayotte **German:** Mayottenektarvogel **Spanish:** Suimanga de Mayotte
Other common names: Mayotte Buff-breasted Sunbird

Taxonomy. *Nectarinia coquerellii* Hartlaub, 1860, no locality = Mayotte, Comoro Islands. Genus often subsumed in *Nectarinia*. This species has been thought to be part of the superspecies formed by *C. sovimanga*, *C. humbloti* and *C. comorensis*, but is quite distinct in plumage from all of these. Recent mitochondrial DNA work suggests that these three, present species and *C. dussumieri* form a clade, and further suggestion is that this clade colonized Indian Ocean islands from continental Africa (at earliest 3.9 million years ago) initially through Comoros; sister-group appears to contain *C. bouvieri*, *C. talatala* and *C. venustus*. Monotypic.

Distribution. Mayotte and nearby islets, in SE Comoros.

Descriptive notes. 10 cm; male 9 g, female 7 g. Male has crown, side of head, throat, back to rump, and lesser and median upperwing-coverts glossy dark green, with small amount of purple iridescence on uppertail-coverts and varying amounts on back; remiges and rectrices black, tinged glossy blue; purple band across upper breast and some purple on throat; pectoral tufts bright yellow, centre of breast orange-red, this colour extending into a point through lower breast to belly; rest of underparts yellow, more buff on vent; iris dark brown; bill and legs black. Female is grey-brown above, rump and uppertail-coverts

greenish, wings darker and browner, wing-coverts plain grey, tail glossy bluish-black; throat to breast pale grey with indistinct darker streaking, rest of underparts yellowish, brighter in centre of belly, whitish on vent, with lower flanks and undertail-coverts greyish-white, underwing-coverts white, axillaries pale yellow; bare parts as male. Juvenile undescribed. Voice. Variety of harsh chipping notes.

Habitat. Forest edge and in open areas; sea-level to 460 m.

Food and Feeding. Insects, including pupae and larvae, spiders (Araneae), and presumably nectar. Few other details.

Breeding. Nest-building observed in Oct and Nov and birds with active gonads also in Oct–Nov. Nest constructed from fine grass, thickly lined with white silken asclepiad pappus, strands of fine grass straggling untidily for c. 10 cm from bottom of nest, similar in size to those of *C. humbloti* and *C. comorensis* but top of entrance only 2 cm from top of nest; suspended 3 m above ground. Male with unossified skull and not yet in full breeding plumage had active testes, indicating possible breeding before full maturity reached. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Restricted-range species: present in Comoro Islands EBA. Common within tiny global range.

Bibliography. Benson (1960, 1970), Cheke & Mann (2001), Hartlaub (1877), Louette (1988), Sinclair & Langrand (1998), Warren *et al.* (2003).

102. Seychelles Sunbird

Cinnyris dussumieri

French: Souimanga des Seychelles **Spanish:** Suimanga de Seychelles
German: Seychellenektarvogel
Other common names: Seychelles Blue-headed Sunbird

Taxonomy. *Nectarinia dussumieri* Hartlaub, 1861, Seychelle Islands. Genus often subsumed in *Nectarinia*. Recent mitochondrial DNA studies indicate that this species belongs to a clade which includes also *C. sovimanga*, *C. humbloti*, *C. comorensis* and *C. coquerellii*, resulting from a colonization of Indian Ocean islands from continental Africa (at earliest 3.9 million years ago) initially through Comoros; sister-group appears to contain *C. bouvieri*, *C. talatala* and *C. venustus*. Was formerly thought perhaps to be close to *Chalcomitra balfouri*, another island species but currently placed in a different genus. Birds on Mahé having almost completely orange pectoral tufts described as a geographical race, *mahe*, but this possibly due to individual variation, and too few specimens available for examination. Treated as monotypic.

Distribution. Seychelle Islands, occurring on Aride, Silhouette, Cousin and Cousine, Praslin, La Digue, Mahé and Frégate.

Descriptive notes. 12 cm. Male is sooty-brown above, rectrices narrowly tipped white; throat to breast metallic darkish blue, sometimes a trace of maroon breastband; pectoral tufts (not gained until second moult) lemon-yellow, yellow-orange or bright orange-red; rest of underparts grey-brown, grading into whitish on vent and undertail-coverts; rectrices with broad white tips on underside; iris grey, brown, maroon or black; bill black; legs dark slate or black. Female differs from male in lacking gloss and pectoral tufts, and has paler feather tips on throat and upper breast (sometimes slight scaled effect), remiges have olive edging, tips of tail grey or white, and underwing-coverts brownish-white, with or without yellowish tinge. Juvenile is similar to female, but slightly

smaller-billed, and underparts sparsely speckled. Voice. Male song a high-pitched squeaky jumble of 6–20 or more notes, beginning as slow "dze-dze-dze-dze" and accelerating to "der-tseet-tseet-tsit-tsit-tsit" or "pse-pser-eu-eu-tsit", sometimes lasting for more than one minute, and may be preceded by rattling trill; also a rapid less squeaky trill; male also delivers complex trilling and throbbing "chee-chee-chee", also a harsh "chesooty-choo" when displaying; quiet repeated "tsuu" with varying rhythm by male. Female song, uttered occasionally, is quieter and less harsh than male's. Calls include repeated "pseeu" at 2-second intervals, "tsick-tsick", "tseet", and insect-like "tziit-tziit"; alarm "chirr"; short "tsuu" or "tsee" by nesting female.

Habitat. Found in almost all habitats, including man-made ones, from sea-level to 900 m.

Food and Feeding. Insects and their larvae, spiders (Araneae) and other arthropods; nectar; known to visit plants of following genera *Albizia*, *Allamanda*, *Averrhoa*, *Bougainvillea*, *Braunsia*, *Camelia*, *Caesalpinia*, *Canna*, *Carica*, *Casuarina*, *Catharanthus*, *Chrysobalanus*, *Cocos*, *Cordia*, *Costus*, *Datura*, *Eucalyptus*, *Eugenia*, *Euphorbia*, *Ficus*, *Gastonia*, *Gliricidia*, *Gossypium*, *Hibiscus*, *Kalanchoe*, *Lantana*, *Mangifera*, *Morinda*, *Musa*, *Nepenthes*, *Petrea*, *Phyllanthus*, *Quiscalis*, *Randia*, *Spathodea*, *Stachytarpheta*, *Tabebuia*, *Tecoma*, *Thespesia*, *Thevetia*, *Thunbergia* and *Turnera*. Forages singly and in pairs, also in mixed-specied parties, mostly at 6–10 m, sometimes down to ground. Techniques include gleaning, probing, hovering and flycatching; takes insects trapped in spider webs. Nectar-robots flowers. Drinks from standing water.

Breeding. Nests found in Sept–Oct and Dec–Jan, and nesting activity in all months except Apr–Jun; several broods. Monogamous or polygynous; sometimes co-operative breeder, young of earlier broods acting as helpers. Territory defended throughout year. Male courts female by singing from prominent perch, with head thrown back, chest feathers puffed, pectoral tufts exposed, while swaying from side to side. Male selects nest-site, but female does most or all of building work, which may take 6 days, nest pear-shaped or coconut-shaped, c. 15.5 × 8.5 cm, often with "tail" up to 30 cm long, entrance sheltered by porch half-way up, constructed from dead grass, some also with *Casuarina* needles, legume fruits, leaves and leaf skeletons, strips of bark or plant stems, strips of coconut fronds, spider webs, down, body feathers of birds (especially of seabirds), cotton, pieces of string, nylon, plastic and other domestic debris, moss and palm fibres, lichens, tendrils, fine roots, skink (Scincidae) skin, and lined with kapok, cotton wool or feathers, mostly downy feathers (obtained from ground, occasionally from air) and even from living chicks of White Tern (*Gygis alba*), suspended 1–20 m above ground from end of tree branch or twig; nest generally well concealed on Mahé and Silhouette, where Seychelles Kestrel (*Falco araea*) occurs. Clutch 1 egg, dirty white with brown spots; incubation by female, period 11–16 days; chicks fed mostly by female, also by any helpers present, nestling period averages 20 days on Aride. Most pairs rear one chick per year, sometimes two or three; rarely four, when male took over feeding of fledglings, allowing female to nest again quickly.

Movements. Resident; some inter-island movement, e.g. individuals found on Aride had been ringed on Cousin, a N movement of 20 km.

Status and Conservation. Not globally threatened. Restricted-range species: present in Granitic Seychelles EBA. Common on all of the wooded islands in the archipelago. Recently recolonized Aride.

Bibliography. Anderson (1994), Beckett (1996), Benson (1967, 1984), Cheke & Mann (2001), Cresswell *et al.* (1997), Delacour (1944), Diamond (1984), Gaymer *et al.* (1969), Gerlach (2001), Greig-Smith (1978, 1980, 1986), Hall & Moreau (1970), Hartlaub (1877), Lucking (1996), Oliver (1991), Owen & Bresson (1987), Penny (1974), Prys-Jones & Diamond (1984), Sinclair & Langrand (1998), Warren *et al.* (2003), Watson (1984), Williams (1953a).

103. Long-billed Green Sunbird

Cinnyris notatus

French: Souimanga angaladian **German:** Stahlnektarvogel **Spanish:** Suimanga Piquilargo
Other common names: Madagascar (Green) Sunbird, Violet-breasted/Violet-green/Noted Sunbird

Taxonomy. *Certhia notatus* Statius Müller, 1776, Madagascar.

Genus often subsumed in *Nectarinia*. No obvious close relative, but has been thought perhaps to form a superspecies with *C. pembae*. Recent mitochondrial DNA studies indicate that it is close to *C. erythrocerus*, *Chalcomitra adelberti*, *Chalcomitra senegalensis* and *Nectarinia kilimensis*; these results furthermore point to an African origin via the Comoro Is, colonists spreading from there to Madagascar. Proposed race *nesophilus* (from Grand Comoro) is treated as a synonym of *moebii*. Three subspecies recognized.

Subspecies and Distribution.

C. n. moebii Reichenow, 1887 – Grand Comoro, in W Comoro Is.

C. n. voeltzkowi Reichenow, 1905 – Mohéli, in W Comoros.

C. n. notatus (Statius Müller, 1776) – Madagascar.

Descriptive notes. 14–15 cm; male 13.8–21.6 g, female 12–21 g. Male nominate race breeding has head to scapulars and back, and uppertail-coverts glossy green, lesser and median upperwing-coverts purple-blue and green, rump glossed green and blue; tail blackish with purple sheen and glossy green edges; upperwing mostly blackish-brown, some violet gloss at carpal joint; chin to breast glossy green, separated by glossy violet-blue band from black and blackish-brown of rest of underparts; iris dark brown; bill and legs black. Male non-breeding (eclipse plumage) is similar to female, but with some metallic feathers.

Female is brown above with olive tinge, with very narrow off-white supercilium, darker feather centres on head and nape (slight scaling effect) appearing as conspicuous longitudinal streaking, tail blackish with bluish sheen, whitish tips on some rectrices, whitish edges on outer feathers; greyish throat and breast, becoming more yellow on lower breast and belly, with heavy dark mottling and streaking, undertail-coverts dark brown with pale edges; bare parts as male. Juvenile is similar to female, but more olive and less brown above, and chin to chest much greyer and with much less obvious mottling. Races differ chiefly in colour of gloss of male: *moebii* male has much purple and

Genus *AETHOPYGA* Cabanis, 1851

105. Grey-hooded Sunbird

Aethopyga primigenia

French: Souimanga de Hachisuka **Spanish:** Suimanga de Hachisuka
German: Grauhauben-Nektarvogel
Other common names: Grey-headed/Hachisuka's Sunbird

Taxonomy. *Philippinia primigenius* Hachisuka, 1941, Galog, 4000 feet [c. 1220 m], Mount Apo, Mindanao, Philippines.
No obvious close relative. Two subspecies recognized.

Subspecies and Distribution.

A. p. primigenia (Hachisuka, 1941) – C Mindanao (Mt Kitanglad, Mt Apo, L Sebu, Mt Busa, Mt McKinley, Mt Lamut, Civolig, Dagawayan), in S Philippines.
A. p. diuatae Salomonsen, 1953 – Mt Hilong-Hilong, in NE Mindanao.

Descriptive notes. 10.8 cm. Male nominate race has iridescent bronze-green forehead and similar-coloured patch on ear-coverts; top of head and neck dark grey, back olive-green, rump bright yellow, tail and upperwing dark olive-brown, tail tipped white; chin and throat dark grey (one specimen with indistinct pale central streak ending in yellow breast spot), breast and centre of belly white, flanks and undertail-coverts yellow; iris deep reddish-brown to brick-red; bill blackish-brown; legs dark brown to dark olive-grey or black, soles pale. Female is similar to male, but lacks iridescence on forehead and ear-coverts. Juvenile not described. Race *diuatae* is greyer below than nominate, throat darker and male with indistinct pale grey-white central streak ending in yellow spot on breast (exhibited also by one male specimen of nominate), centre of belly greyer and with very indistinct darker grey streaks, and iridescence on forehead of male is more extensive. Voice. Repeated high-pitched “pink-pink-pink”, level or ascending, and may become “see-see-see...”; also “seek-seek” up to six times.

Habitat. Forest and forest edge; 1000–1700 m.
Food and Feeding. Often seen around banana flowers; no other information.
Breeding. Birds with active gonads in Nov–Feb. No other information.
Movements. No data.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Mindanao and the Eastern Visayas EBA. Common within its small range. Although its habitat appears not to be under any immediate threat, the species is considered at risk on account of its very small global range.

Bibliography. Anon. (2007f), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), David & Gosselet (2002a), Dickinson *et al.* (1991), Kennedy *et al.* (2000), duPont (1971b), Rand (1950b), Ripley & Rabor (1961), Salomonsen (1953b), Stattersfield & Capper (2000).

106. Apo Sunbird

Aethopyga boltoni

French: Souimanga de Bolton **German:** Mindanaonektarvogel **Spanish:** Suimanga de Bolton
Other common names: Mount Apo Sunbird

Taxonomy. *Aethopyga boltoni* Mearns, 1905, Mount Apo, 6250 feet [c. 1900 m], Mindanao, Philippines.
Forms a superspecies with *A. linaraborae*. Three subspecies recognized.

Subspecies and Distribution.

A. b. malindangensis Rand & Rabor, 1957 – Mt Malindang, in W Mindanao (S Philippines).
A. b. boltoni Mearns, 1905 – Mt Kitanglad, Mt McKinley and Mt Apo, and presumably Mt Pasian, in C Mindanao.
A. b. tibolii Kennedy *et al.*, 1997 – Mt Busa and Mt Matutum, and presumably Mt Parker and L Sebu, in S Mindanao.

Descriptive notes. Male 12 cm, 4.9–9.2 g; female 10.8 cm, 6–8.5 g. Male nominate race has head dark grey, becoming olive-green on back and upperwing, forehead with metallic greyish-green fringes, rump light yellow, and graduated tail black with metallic green gloss, rectrices except central two tipped white; chin and throat light yellow, bordered dark grey at side, breast orange-yellow, bright orange pectoral tufts, belly olive-yellow; iris red; bill black; legs black, soles yellowish. Female has head olive-grey, paler than in male, nape to upper back olive, becoming greener on wing-coverts and lower back, and some yellow on

rump; remiges blackish, edged bright olive, graduated tail blackish with slight green sheen; chin whitish, throat to upper breast olive-grey with indistinct paler stripes, rest of breast more yellowish, with dull orange suffusion on lower breast, rest of underparts and pectoral tufts yellow, brighter on flanks, with some orange on centre of belly; underside of central three pairs of rectrices with large grey tips; bare parts as male. Juvenile of nominate race undescribed; for race *tibolii*, juvenile male paler than adult, less yellow on throat, lacking orange in breast and belly and pectoral tufts, juvenile female similar to adult but paler. Races differ chiefly in coloration of underside of male: *malindangensis* is generally brighter than nominate, male also has more extensive orange centre on

breast, more red on side of breast, brighter yellow flanks and abdomen, more iridescence on forehead and crown, female has more and brighter orange on lower breast and brighter yellow flanks and abdomen; *tibolii* is less richly coloured than nominate, lower breast and patch on belly orange-yellow (not orange) and pectoral tufts paler, female has edges of secondaries paler, chin and throat pale grey with fine white streaking, belly paler yellow. **Voice.** Song rapidly produced, rising, squeaky, high-pitched trill of c. 15 notes, or rapid even-pitched decelerating trill, or continuous “sip-sip-sip” or “clip-clip-clip”. Calls include series 2–3 seconds long of ascending snapping notes, repeated after short pause; rapid, continuous, metallic snapping “twit-twit-twit...”, which may change to whistled “whirr”; 1–6 bubbling “peep” notes, first ones separated, the rest rapid.

Habitat. Forest, generally above 1500 m, sometimes down to 1100 m.
Food and Feeding. Forages singly and in pairs; joins mixed-species flocks. No other information available.

Breeding. Nesting recorded in Jan–May and Jul, and birds with enlarged gonads in Mar–Apr. Nest a pendulous bag, 8 × 16 cm, with side entrance, made from loosely woven moss, and spider and insect cases, suspended c. 2.4 m above ground from small branch in tree or bush, or from tall grass, or on outside of clump of ferns. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Mindanao and the Eastern Visayas EBA. Common within its range. Although its habitat appears to be secure, this species is considered to be potentially at risk because of its very small global range.

Bibliography. Anon. (2007f), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), Dickinson *et al.* (1991), Harrop & Fisher (2007), Hornsbov (1996), Kennedy, Gonzales, Dickinson *et al.* (2000), Kennedy, Gonzales & Miranda (1997), McGregor (1909), duPont (1971b), Rand & Rabor (1957, 1960), Ripley & Rabor (1961), Stattersfield & Capper (2000).

107. Lina's Sunbird

Aethopyga linaraborae

French: Souimanga de Lina **German:** Linanektarvogel **Spanish:** Suimanga de Lina

Taxonomy. *Aethopyga linaraborae* Kennedy *et al.*, 1997, 1200 m, near peak of Mount Pasian, Davao del Norte Province, Mindanao, Philippines.
Forms a superspecies with *A. boltoni*. Monotypic.

Distribution. E Mindanao (Mt Pasian, Mt Puting Bato, Mt Mayo), in S Philippines.

Descriptive notes. Male 10.8 cm, 5.7–8.7 g; female 10.2 cm, 6–7 g. Male has forehead metallic emerald-green with hint of blue, ear patch metallic cobalt-blue, head otherwise blackish-grey, crown feathers edged metallic blue, back olive-green with clearly defined sulphur-yellow rump, uppertail-coverts deep metallic emerald-green; tail feathers blackish-grey, edged violet, all except central feathers with whitish-silver tips; lesser and median upperwing-coverts bright metallic emerald-green, greater coverts metallic ultramarine, remiges dark brown, edges of scapulars and secondaries cobalt-blue; chin to upper breast

sulphur-yellow, small orange flecks on upper breast and orange patch in centre of breast, pectoral tufts scarlet, lower breast and belly yellow, undertail-coverts sulphur-yellow, and wing-lining white (individual variation in brightness of yellow underparts and size of orange breast patch); iris dark brick-red to blood-red, skin around eye blackish-brown; bill black; legs dark brown to black, soles pale ochre-yellow. Female has more muted colours than male, and lacks metallic sheen on forehead, ear-coverts, uppertail-coverts and wing-coverts; head dark grey with trace of pale metallic emerald-green feather edges, and olive-green of back grades into olive-tinged sulphur-yellow at tail base; edges of tail feathers metallic cobalt-blue, wing-coverts olive-green, remiges edged orange olive-yellow; throat yellowish olive-green and breast to belly yellowish-olive, all with indistinct olive-yellow streaking, diffuse orange patch on centre of lower breast and belly; bare parts as male. Juvenile undescribed. **Voice.** Song a long series of high-pitched squeaky twittering notes with repeated sequences. Calls include high-pitched “sweet”, sometimes with upward inflection, repeated two to three times at 5-second intervals, or more frequently repeated at irregular intervals.

Habitat. Montane forest, from 1000 m upwards.
Food and Feeding. Forages singly and in pairs, and occurs also in mixed-species flocks. No other information.

Breeding. Birds with enlarged gonads in May. No other information.

Movements. No information.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Mindanao and the Eastern Visayas EBA. Common within its very small range. Considered to be potentially at risk mainly because of the tiny extent of its overall range.

Bibliography. Anon. (2007f), Butchart & Stattersfield (2004), Cheke & Mann (2001), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), Kennedy, Gonzales, Dickinson *et al.* (2000), Kennedy, Gonzales & Miranda (1997), Stattersfield & Capper (2000).

108. Flaming Sunbird

Aethopyga flammans

French: Souimanga flamboyant **Spanish:** Suimanga Llamanteante
German: Feuerbrust-Nektarvogel

Taxonomy. *Aethopyga flammans* Oustalet, 1876, Lagune, Luzon, Philippines.
Possibly part of the superspecies formed by *A. boltoni* and *A. linaraborae*. Race *decolor* possibly inseparable from nominate. Proposed race *excellens* (described from Manito, in Albay District of SE Luzon) considered unsustainable, and is synonymized with nominate. Four subspecies provisionally recognized.

Subspecies and Distribution.

A. f. decolor Parkes, 1963 – N Luzon, in N Philippines.
A. f. flagrans Oustalet, 1876 – C & S Luzon and Catanduanes.
A. f. guimarasensis (Steere, 1890) – Panay and Guimaras, in WC Philippines.
A. f. daphoenonota Parkes, 1963 – Negros, in SC Philippines.

Descriptive notes. 9.5 cm. Male nominate race has forehead and forecrown metallic blue-green, hindcrown, back and upperwing-coverts bright olive-yellow, washed orange or bronzy golden on mantle and scapulars, uppertail-coverts metallic blue-green, tail black, edged metallic green; remiges edged greenish; malar stripe to chin and upper throat dark metallic purple, lower throat and breast dull black, bright reddish-orange to scarlet spot or medial stripe on central breast, rest of abdomen yellow with orange patch on centre of lower breast and upper belly, paler yellowish-grey on flanks and vent, undertail-coverts whitish; iris dark

brown, bill blackish, legs dark brown, often paler and more fleshy coloured on soles. Female has head and upperparts olive-green, throat and underparts greyer, with yellowish patch on lower breast. Juvenile undescribed. Race *decolor* male differs from nominate in having yellow-olive upperparts, and breast stripe and patch on belly less red (one specimen identical to nominate in this character); *guimarasensis* male differs in having hindcrown to mantle blood-red or dark orange-red to maroon-chestnut, wing-coverts and edges greenish, and yellow on underparts much brighter, with less orange on belly; *daphoenonota* male has more extensive blood-red to dull maroon on mantle than previous, more extensive and deeper orange on underparts, and wing-coverts and edges orange, female also has orange edgings and is greener (and grey) above. **VOICE.** Short, high-pitched rising “tsweet”, repeated at intervals.

Habitat. Forest, forest edge and secondary growth; sea-level to 1350 m.

Food and Feeding. No information on diet. Forages singly, in pairs and in mixed-species flocks.

Breeding. Males with enlarged testes in Apr on Luzon. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Uncommon. Occurs in Quezon National Park, on Luzon.

Bibliography. Cheke & Mann (2001), Dickinson *et al.* (1991), Goodman & Gonzales (1990), Kennedy *et al.* (2000), McGregor (1909), Parkes (1963), duPont (1971b), Rand (1951a).

109. Metallic-winged Sunbird

Aethopyga pulcherrima

French: Souimanga montagnard

Spanish: Suimanga Submontano

German: Glanzflügel-Nektarvogel

Other common names: Mountain Sunbird

Taxonomy. *Aethopyga pulcherrima* Sharpe, 1876, Basilan, Philippines.

No obvious close relatives, but has been suggested that this species forms a superspecies with *A. duyvenbodei*. Proposed race *dubia* (described from Dinagat) seems insufficiently distinct from nominate to be tenable. Three subspecies recognized.

Subspecies and Distribution.

A. p. jefferyi (Ogilvie-Grant, 1894) – N & C Luzon, in N Philippines.
A. p. pulcherrima Sharpe, 1876 – Samar, Biliran, Leyte, Dinagat, Siargao, Mindanao and Basilan.
A. p. decorosa (McGregor, 1907) – Bohol.

Descriptive notes. 9.6 cm; unsexed 4.4–7.5 g. Male nominate race has forehead and spot behind eye metallic purplish-green or steel-blue, crown to back olive-green, rump bright yellow, uppertail-coverts and upperwing-coverts metallic green; tail black, glossed metallic green, and remiges olive-green; chin and throat bright yellow, breast yellowish with small orange-red patch, belly greyish-yellow; iris blood-red; bill blackish; legs dark brown. Female differs from male in having entire upperside except rump olive-green, and throat and underparts dull olive-grey, with some yellowish especially on breast. Juvenile differs from female in having

rump and underparts paler yellow, iris yellowish-brown, bill brown, legs dark grey with soles ochraceous. Race *jefferyi* male differs from nominate in dark metallic blue forehead, bright yellow lower back concolorous with rump, and metallic green edging on remiges; *decorosa* male differs from previous in metallic purple-blue edging on remiges, metallic blue (not green) wing-coverts, uppertail-coverts and tail, has paler yellow rump, much paler underparts, and red breast patch very small or absent, female differs in having much lighter rump patch. **VOICE.** Song slow, consisting of well-spaced notes followed by long high-pitched trill, followed by a further series of slow spaced notes. Calls a repeated “squeak”, and repeated high-pitched “zeeep”; high-pitched “zip zip” which may accelerate into metallic trill; sharp “see”, or “see-see, tsik tsik”, becoming short rising trill.

Habitat. Forest, forest edge, secondary growth and plantain (*Musa*) plantations. Usually submontane to 1700 m; also in lowlands on Mindanao, and to 2000 m on Luzon.

Food and Feeding. No data on diet. Forages singly and in mixed flocks.

Breeding. Laying recorded in Apr–Jul, and birds with active gonads in Mar–May. Nest attached to climbing fern 2–4 m above ground. Clutch 3 eggs, dull pink, mottled pinkish-grey, spotted deep brown. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Common to fairly common throughout range.

Bibliography. Cheke & Mann (2001), Dickinson *et al.* (1991), Goodman & Gonzales (1990), Kennedy *et al.* (2000), McGregor (1907, 1909), Ogilvie-Grant & Whitehead (1898), duPont (1971b), Rand & Rabor (1960).

110. Elegant Sunbird

Aethopyga duyvenbodei

French: Souimanga des Sangi

German: Sangihenektarvogel

Spanish: Suimanga Elegante

Other common names: Duyvenbode’s/Sangihe/Sanghir (Yellow-backed) Sunbird

Taxonomy. *Nectarinia duyvenbodei* Schlegel, 1871, Sanghir Island (= Sangihe), north of Sulawesi. No obvious close relatives, but has been suggested that this species may form a superspecies with *A. shelleyi*, *A. bella* and/or *A. pulcherrima*. Monotypic.

Distribution. Sangihe I; also one specimen from Siau.

Descriptive notes. 12 cm. Male has crown metallic green (sometimes appearing blue), nape side, neck and ear-coverts maroon-red, mantle and back dark olive-green, upperwing-coverts glossed greenish-blue, shoulder glossed blue, rump deep yellow, uppertail-coverts metallic purple; remiges blackish, metallic blue edging on inner secondaries, rounded tail blackish-brown with whitish edging and pale grey tips; forehead dull blackish, often with some dull yellow on lores, bright yellow eyering broken into upper and lower halves, underparts yellow, with richer, more orange tinge to central abdomen, dark green of mantle

extends as indistinct bar onto breast side, rest of underparts orange-yellow; iris black; bill black or blackish; legs blackish or reddish-pink. Female has lores olive; is dark golden-olive above, with indistinct scaling on forehead and crown, wings brownish, edged greenish, primaries noticeably darker, edged greenish-olive, and tail blackish, tipped grey; throat to upper breast greenish-yellow, narrow darkish olive band across lower throat separating it from breast, and rest of underparts bright yellow; bare parts as male. Juvenile is similar to female, but with pale pinky-brown bill and legs. **VOICE.** Male song a very short, high, insect-like trill; male also produces a high trill of chipping notes. Calls include high-pitched and rasping “treek” or “tseek”; also “tit”, given singly or up to four in rapid sequence; various squeaky notes.

Habitat. Remnant forest, bamboo, mixed plantations, secondary forest, scrub and tree-ferns; to 900 m.

Food and Feeding. Diet includes insects and nectar. Forages singly and in pairs, sometimes in small groups; joins mixed-species flocks. Insects are taken from vegetation or extracted from spider webs.

Breeding. Birds with enlarged gonads in May, recently vacated nest in Aug, juveniles observed in Aug–Sept, and singing and lek-like behaviour recorded in Nov–Dec; data suggest two breeding seasons. No other information.

Movements. Nothing recorded.

Status and Conservation. ENDANGERED. Restricted-range species: present in Sangihe and Talaud EBA. Uncommon to locally more common. Has fragmented population, and undergoing continuing decline owing to loss and degradation of habitat. Presence in Siau questionable; one specimen apparently taken there in 1866. On Sangihe, common in forest and plantations on Mt Sahengbalira in Aug 2004. Global population estimated as 2500–9999 individuals, in total range of c. 560 km², within which it has been recorded from Talawid Atas, Kedang, Mt Awu, Petta, Manganitu, Mt Sahendaruman, Mt Sahengbalira, Mt Palenti, Kentuhang, Ulung Peliang, Tabukan and Tahuna. Tiny remnant of primary forest surviving on Sangihe inadequately protected and continues to suffer from agricultural encroachment at lower fringes; forest on Mt Sahendaruman nominally conserved. Since 1995, fieldwork and conservation-awareness programmes have been conducted, and ideas developed for future land use, through agreements between interested parties. Proposals made to reclassify the 4 km² of “protection forest” on Mt Sahengbalira as a wildlife reserve, and some forest in Kentuhang valley is protected as watershed for a hydro-electric scheme. Other proposals include establishment of permanent presence of forestry staff on Sangihe I.

Bibliography. Anon. (2007), Bishop (1992), Butchart & Stattersfield (2004), Cheke & Mann (2001), Coates & Bishop (1997), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Riley (1997), Riley *et al.* (1999), Stattersfield & Capper (2000), White & Bruce (1986).

111. Lovely Sunbird

Aethopyga shelleyi

French: Souimanga de Palawan **German:** Goldkehl-Nektarvogel **Spanish:** Suimanga Filipino

Other common names: Palawan/Shelley’s(!) Sunbird

Taxonomy. *Aethopyga shelleyi* Sharpe, 1876, Palawan, Philippines.

Forms a superspecies with *A. bella*, previously treated as conspecific; has been suggested that *A. duyvenbodei* may be part of this superspecies. Monotypic.

Distribution. Busuanga, Culion, Palawan and Balabac, in W Philippine Is.

Descriptive notes. Male 10.5 cm, female 8.4 cm. Male has crown metallic purple and green, side of head, hindneck and upper back dark red, lower back and rump bright yellow, uppertail-coverts and graduated tail metallic blue-green, upperwing yellowish-green; chin and throat yellow with red margin, blue-green malar stripe, breast yellow with red streaking, belly pale grey; iris black; bill and legs dark brown. Female has dull olive-green upperparts, greyer on head; narrow eyering whitish, throat and breast pale greyish-yellow, yellower on centre of abdomen, whiter on rest of underparts. Juvenile similar to female, but much

greyer below, with buffy centre of breast and belly. **VOICE.** Seesawing “zuep-zip” for several seconds.

Habitat. Forest, forest edge and cultivation, often around flowering and fruiting trees; sea-level to 2000 m.

Food and Feeding. Feeds on small insects and their larvae, and nectar. Forages singly and in pairs; joins mixed-species flocks.

Breeding. Laying recorded in Feb. No further information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Locally common. Occurs in St Paul Subterranean River National Park, on Palawan.

Bibliography. Cheke & Mann (2001), Dickinson *et al.* (1991), Kennedy *et al.* (2000), Mann (2002), McGregor (1909), Ogilvie-Grant & Whitehead (1898), duPont (1971b), Zimmer (1918).

112. Handsome Sunbird

Aethopyga bella

French: Souimanga oreillard **German:** Philippinennektarvogel **Spanish:** Suimanga Hermoso
Other common names: Lovely(!)/Shelley's(!) Sunbird

Taxonomy. *Aethopyga bella* Tweeddale, 1877, Surigao, north Mindanao, Philippines. Forms a superspecies with *A. shelleyi*, previously treated as conspecific; it has been suggested that *A. duyvenbodei* may be part of this superspecies. Race *minuta* not well differentiated, and validity has been questioned. Six subspecies recognized.

Subspecies and Distribution.

A. b. flavipectus Ogilvie-Grant, 1894 – N Luzon, in N Philippines.
A. b. minuta Bourns & Worcester, 1894 – S & C Luzon, Polillo Is, Mindoro and Marinduque.
A. b. rubrinota McGregor, 1905 – Lubang.
A. b. bonita Bourns & Worcester, 1894 – Panay, Masbate, Ticao, Negros and Cebu.
A. b. bella Tweeddale, 1877 – Samar, Leyte, Dinagat, Siargao and Mindanao, in E & S Philippines.
A. b. arolasi Bourns & Worcester, 1894 – Sulu Archipelago (Jolo and Tawi-Tawi).

Descriptive notes. Male 9.1 cm, 3.9–5.3 g; female 8.3 cm, 3.1–4.2 g. Male nominate race has crown to rear of eye metallic green, rest of crown and nape unglossed dark green, side of head and upper back dark red, glossy purple spot on cheek; lower back and rump bright yellow, uppertail-coverts and graduated tail metallic blue-green, upperwing yellowish-green; chin and throat yellow (with or without variable amounts of red or orange), blue-green malar stripe, breast yellow with red streaks, abdomen and undertail-coverts pale grey to yellow; iris black; bill with upper mandible blackish, lower mandible dark brown, legs dark brown. Female is olive-green above, duller on head, with yellow rump; white eyering, pale underparts with yellowish-olive tinge, especially on throat and breast. Juvenile is as female, but much greyer below, with buffy centre of breast and belly. Race *arolasi* is larger than nominate, male has heavier orange-red streaking on breast and

belly, and yellower abdomen and undertail-coverts, female has less yellow on rump; *minuta* male is similar to previous but smaller, and throat is pure yellow with no red or orange; *flavipectus* male has little or no red on breast, and only forecrown is glossed green; rest of crown and nape unglossed dark green; *rubrinota* male differs from last in having slightly lighter yellow on breast, and has slight bluish cast in forehead; *bonita* male is darker yellow on lower back and rump than nominate, breast more heavily streaked red. **Voice.** Rapid “sit-sit-sit-tee-tee-tee-tee”, last notes at lower pitch; also “tsit-tit-tit-it”.

Habitat. Thickets, cultivation, forest and forest edge; sea-level to 2000 m.

Food and Feeding. Feeds on small insects and their larvae, and nectar. Forages singly and in pairs; joins mixed-species flocks.

Breeding. Breeding recorded in Jan, Jun–Jul and Sept. One nest (nominate race) a long bag-shaped pocket with loose dangling “tail” of dead leaves, side entrance roofed over, suspended from bramble (*Rubus*) in old clearing some distance from forest. Clutch 3 eggs, pale pinkish-white, heavily marked with irregular zone of dull red towards large end, scattered spots and blotches of same colour over rest of shell, and underlying brown markings. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Locally common throughout most of Philippines.

Bibliography. Cheke & Mann (2001), Dickinson *et al.* (1991), Kennedy *et al.* (2000), Mann (2002), McGregor (1905b, 1909), Ogilvie-Grant & Whitehead (1898), duPont (1971b), Rand & Rabor (1960), Ripley & Rabor (1958), Tweeddale (1877b).

Aethopyga gouldiae

Taxonomy. *Cinnyris gouldiae* Vigors, 1831, Himalayas = Simla–Almora District, north India. Additional proposed races are *trochiloidea* (described from Blue Mountain, in Lushai Hills of NE India) and *melitae* (Mt Victoria, in W Myanmar), both subsumed in *isolata*, and *harrietae* (Phu Kobo, near Xiangkhouang, in Laos) and *bangsi* (Hongsurkou, in Hubei, in C China), which are synonymized with *dabryi*. Four subspecies recognized.

A. g. annamensis Robinson & Kloss, 1919 – S Laos and SC Vietnam.

Bibliography. Ali & Ripley (1974), Cheke & Mann (2001), Échécopar & Hüs (1983), Fleming & Traylor (1968), Fleming *et al.* (1976), Gaston (1989), Gretton (1990), Grimmett *et al.* (1998), Inskip & Inskip (1985), King *et al.* (1975), McClure (1998), Melville & Round (1984), Meyer de Schauensee (1940), Oates (1890a), Rasmussen & Anderson (2005b), Ripley (1953), Robson (1988, 2000b), Traylor (1967), Vuilleumier (1993).

Aethopyga nipalensis

Taxonomy. *Cinnyris nipalensis* Hodgson, 1837, Chandragiri Pass, central Nepal. Race *horsfieldi* intergrades with nominate in W Nepal. In India, proposed race *griseiceps* (from Ghoom, near Darjeeling) considered inseparable from nominate and *ripleyi* (from Mawryngkneng, in Khasi Hills) synonymized with *koelzi*. Nine subspecies recognized.

A. n. koelzi Ripley, 1948 – Bhutan and NE India (Arunachal Pradesh, Meghalaya and Nagaland S to Chittagong Hills) E to S China (S Xizang E to C Sichuan and NW Yunnan) and N Vietnam.

Bibliography. Ali & Ripley (1974), Birand & Pawar (2004), Cheke & Mann (2001), Ètchécopar & Hùc (1983), Fleming (1968), Fleming *et al.* (1976), Grinnett *et al.* (1998), Inskip & Inskip (1985), King *et al.* (1975), Melville & Round (1984), Meyer de Schauensee (1984), Rand & Fleming (1957), Rasmussen & Anderton (2005b), Ripley (1953, 1961a), Robson (2000a, 2000b), Smythies (1986), Stepanyan (1985b), Wells (2007).

Aethopyga eximia

iris brown, bill black; legs black or brownish-black. Female is dull olive above, greyer on head,

dark olive-green below, greyish on throat, with white underwing-coverts, pectoral tufts and flanks; tail much shorter than male's, and rounded. Juvenile is as female but more brownish, particularly below, and darker grey on throat. **Voice.** Clear "tee-tee-tee-leet" with variations.

Habitat. Forest, forest edge, clearings, and alpine scrub above tree-line; 1200–3000 m.

Food and Feeding. Diet thought to include nectar and small arthropods. Forages singly, in pairs and in small groups; mostly in lower and middle storeys. Often around flowering trees and vines; recorded around mistletoes (Loranthaceae).

Breeding. Laying in Jan, Mar–Jun, Nov and Dec. Nest a pouch of moss and other materials, suspended high up in forest tree. Eggs greyish-white with small dark brown spots and clouds, markings forming heavy cap. No other information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Restricted-range species; present in Java and Bali Forests IBA. Common, particularly above 2400 m. Occurs in Gunung Gede-Pangrango National Park.

Bibliography. Cheke & Mann (2001), Hebbekers & Hoogerwerf (1967), Hoogerwerf (1949, 1950), MacKinnon & Phillips (1993).

116. Fork-tailed Sunbird

Aethopyga christinae

French: Souimanga de Christine **German:** Hainannektarvogel **Spanish:** Suimanga de Christina

Taxonomy. *Aethopyga christinae* Swinhoe, 1869, Hainan Island, south China.

This species and *A. eximia* have in the past been placed together in a separate genus, *Urodrepanis*, but no evidence that they are particularly closely related. Three subspecies recognized.

Subspecies and Distribution.

A. c. latouchii Slater, 1891 – SE China (E Sichuan E to Fujian, S to Guangxi and Guangdong), N Vietnam and C Laos.

A. c. christinae Swinhoe, 1869 – Hainan I.

A. c. sokolovi Stepanyan, 1985 – S Vietnam.

of belly; iris brown or dark brown; bill black or reddish-brown; legs brown. Female has crown dull brownish or blackish with greyish-olive edging (giving sealy appearance), upperparts olive-green, chin, throat and breast light yellowish-green, rest of underparts greenish-yellow; bare parts as male. Juvenile is as female, but greyer above and on throat and upper breast; young male develops longer tail and yellow rump before acquiring iridescence. Race *latouchii* male has back yellowish-olive (as wing), chin to breast maroon-crimson; *sokolovi* male is similar to previous, but has darker olive back, blackish side of head tinged reddish, yellow area on upperparts larger and darker, breast, belly and undertail-coverts olive-green to green. **Voice.** Song an accelerating "pe-et, pe-et, pit, pit". Calls "twisk", singly or repeated up to five times; also "chip-chip", developing into slightly descending trill of 5–8 notes.

Habitat. Forest and forest edge, occasionally gardens; generally on lower hills, up to 1400 m.

Food and Feeding. Few data. Diet seeds, and presumably nectar and small arthropods. Visits flowering bushes and trees.

Breeding. Laying from Apr onwards in China. Nest pear-shaped, constructed from mosses, grasses, plant fibres, sometimes decorated with lichens, and suspended from leaves on a branch. Clutch 2–4 eggs, greenish-grey, with purplish markings tinged reddish-brown, with dusky dots. No other information.

Movements. In China, moves into S Guangdong and C Fujian in winter months.

Status and Conservation. Not globally threatened. Common in China; fairly common within somewhat limited range in SE Asia. Occurs in Cue Phuong National Park, in Vietnam.

Bibliography. Caldwell & Caldwell (1931), Cheke & Mann (2001), Corlett (1998), Étiéopcar & Hûe (1983), King *et al.* (1975), Lei Jinyu & Liu Yang (2006), Liu Yang & Lei Jinyu (2005), Meyer de Schauensee (1984), Prinzing, Lübben & Schuchmann (1989), Prinzing, Schäfer & Schuchmann (1992), Robson (1994a, 2000a, 2000b), Stepanyan (1985a).

117. Black-throated Sunbird

Aethopyga saturata

French: Souimanga sombre **German:** Schwarzkehl-Nektarvogel **Spanish:** Suimanga Gorjinegro
Other common names: Hodgson's/Black-breasted Sunbird

Taxonomy. *Cinnyris saturata* Hodgson, 1836, Nepal.

Geographical variation extremely well marked in some cases, isolated race *wrayi* perhaps approaching species level. Birds in Cambodia (except SW) of uncertain racial identity. Proposed race *ariel*,

described from near Nokrek (in Garo Hills), in NE India, considered inseparable from *assamensis*. Ten subspecies recognized.

Subspecies and Distribution.

A. s. saturata (Hodgson, 1836) – Himalayas from N India (Garhwal and Mussoorie) E to Nepal, Bhutan and S China (SE Xizang).

A. s. assamensis (McClelland, 1839) – NE India, N Myanmar and S China (W Yunnan).

A. s. petersi Deignan, 1948 – E Myanmar, extreme N Thailand, N Laos, N Vietnam and SE China (SE Yunnan, W Guangxi).

A. s. galenae Deignan, 1948 – NW Thailand.

A. s. sanguinipictus Walden, 1875 – SE Myanmar.

A. s. anomala Richmond, 1900 – S Thailand (S to Trang).

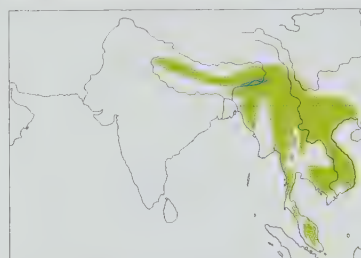

A. s. wrayi Sharpe, 1887 – Malay Peninsula S of Trang.

A. s. ochra Deignan, 1948 – S Laos and C Vietnam.

A. s. cambodiana Delacour, 1948 – SW Cambodia.

A. s. johnsi Robinson & Kloss, 1919 – S Vietnam.

Also N & E Cambodia (race as yet undetermined).

Descriptive notes. Male 14–15 cm, 5.5–6.5 g; female 10 cm, 5.5 g. Male with elongated central tail feathers. Male nominate race has crown and nape metallic violet-purple, side of neck and back crimson-brown or maroon, variably narrow yellow band on lower back (sometimes absent), uppertail-coverts metallic purple-blue; uppertail metallic purple-blue, upperwing blackish-brown; lores, face and throat to upper breast blackish, broad metallic purple or blue malar stripe, lower breast unglossed blackish, rest of underparts pale greyish-olive to greenish-grey; iris brown; bill brownish-black to black; legs dark horn-brown to dark

brown. Female is olive-green above, with crown grey, yellow band on lower back, tail graduated and with greyish-white tips; greyish-olive below, except for whitish flanks. Juvenile is similar to female, but tail not so graduated, and white tips not so distinct; male later developing dark maroon on mantle, wings, tail and breast. Race *assamensis* male is richer in colour than nominate, with a little more yellow on lower back, belly dull olive-green and grey, female entirely greenish below with little or no yellow tinge; *petersi* male has glossy blue crown and moustachial stripe, unglossed black chin to breast, sulphur-yellow lower breast streaked scarlet, belly, flanks and vent olive-yellow; *galenae* male has mixed scarlet and yellow breast, greenish-grey lower breast, belly and flanks, differs from previous in sulphur-yellow breast patch being more extensive distally and less clearly separated from olivaceous yellow (rather than greyish olive-green) of rest of underparts, female in having lower underparts yellowish (rather than greyish olive-green); *sanguinipictus* male differs from preceding race in having entire throat except centre metallic blue-violet, fewer red streaks on chest; *cambodiana* male differs from last in having darker red on back; *anomala* male has no yellow on lower back/rump, has throat to upper breast dull smoky black with glossy purple border, lower breast to vent greyish, with dull yellowish band across breast; *johnsi* male has breast entirely scarlet with narrow yellow streaks, belly, vent and flanks olive-green or greyish-green, female has entire underparts greenish with little or no yellow tinge; *wrayi* male has very little yellow on rump, breast sooty black with feathers tipped yellowish, belly, flanks and vent greyish olive-green, only few red streaks on breast; *ochra* male has more extensive yellow on underparts than last, female below entirely greenish with little or no yellow tinge. **Voice.** Song a twittering containing series of sharp, high-pitched "swi", "tis" and "tsi" notes with rapid metallic trills, e.g. "swi, it, it, it, it, it" or "swi, i, i, i, i, i". Calls include high-pitched, repeated, rather thin "tit, tit-tit" or "tiss-it", and "tu-ti-tee-tee".

Habitat. Primary forest, heavily disturbed forest and regenerating secondary forest, dense jungle edge, scrub, secondary growth, gardens and along shady streams. At 820–2200 m; down to 305 m in winter.

Food and Feeding. Nectar, including that from *Aeschynanthus*, *Rhododendron* and *Lantana*, and perhaps pollen; also arthropods. Forages singly and in pairs, from canopy down to understorey, sometimes on ground. Nectar-robbs flowers.

Breeding. Laying in Jan–Mar in India, Feb–May and Sept in Nepal, Apr in Myanmar; in Malay Peninsula, laying calculated as Feb–Apr and Jun, but nest-building observed in mid-Mar, May and Sept, nestlings found Feb and Mar and fledglings in late Apr; birds with enlarged gonads in Apr in Thailand. Nest, apparently built by female alone, is pear-shaped, entrance hole one-third from top and with porch 2–3 cm (or without porch), made from felted vegetable down or dry grass, moss (especially on upper half), lichens, rootlets, fibre from fern rhizomes, and cobwebs, decorated externally with wood chips and bamboo leaves, lined with soft seed down, attached to thin branch of bush or creepers or to tips of tree-fern fronds up to 4 m above ground. Clutch 1–3 eggs, white, with inky black, inky brown or muddy brown speckles, spots and blotches. No further information.

Movements. Mostly resident. Known to make some seasonal altitudinal movements in higher parts of range.

Status and Conservation. Not globally threatened. Fairly common to common in India, Nepal and Bhutan; uncommon in Thailand; common to uncommon in Malay Peninsula. Status in Bangladesh uncertain; may have occurred in past, but now extirpated. Nominative race possibly occurs in NE Pakistan (Murree Hills). Occurs in several protected areas, such as Namdapha National Park, in India, and Kaeng Krachan National Park, in Thailand.

Bibliography. 118. Vigors's Sunbird

Aethopyga vigorsii

French: Souimanga de Vigors **German:** Vigorsnektarvogel **Spanish:** Suimanga de Vigors
Other common names: (Vigors's) Yellow-backed Sunbird, Western Crimson Sunbird

Taxonomy. *Cinnyris vigorsii* Sykes, 1832, Western Ghats, Deccan, India. Forms a superspecies with *A. siparaja*, and often treated as conspecific. Proposed race *concolor* (described from W Deccan) appears to be undiagnosable. Monotypic.
Distribution. NW Maharashtra (W Satpuras) and Western Ghats (from R Narmada S at least to Goa area), in W India.

Descriptive notes. Male 15 cm, 7.9 g; female 10 cm, 7.7 g. Has heavy, strongly curved bill. Male has forehead to centre of crown metallic blue-green, metallic violet or blue cheek spot; nape to mantle and shoulders dark, dull crimson-red, back blackish, patch on lower back pale yellow; uppertail-coverts and elongated narrow central tail feathers blackish-brown, edged metallic blue, outer rectrices tipped dark grey, edges of other tail feathers metallic green; upperwing blackish-brown; throat to breast scarlet with obvious yellow streaks. Metallic violet or blue malar streak, breast bordered below by thin blackish band which extends

downwards to form narrow black patch; rest of underparts grey, underwing-coverts and axillaries white; iris red-brown to crimson; bill blackish, dark brown below; legs dark brown to blackish. Female has crown, nape and mantle greyish-olive, back olive, brightening to olive-yellow on rump and uppertail-coverts; tail black, outer webs tipped olive, inner webs tipped white, central feathers olive, wing dark brown, edged olive; chin whitish-grey, throat to breast olive-grey, rest of underparts grey, some individuals with chin to breast dull orange-scarlet; bare parts as male. Juvenile male is occasionally like adult female, but with dull scarlet throat and breast (possibly a transitional stage, rather than a discrete plumage); juvenile female as adult but greyer below. **VOICE.** Sharp, harsh "chi-wee"; also "shwing!", said to be richer, more strident and more slurred than similar call of *A. siparaja*.

Habitat. Evergreen and moist-deciduous forest, and forest edge, particularly around flowering trees and shrubs, foothills, to 1000 m.

Food and Feeding. Nectar; presumably also small insects, and spiders (Araneae). Forages mostly in small groups, generally in upper levels but often lower.

Breeding. Season Jun–Oct. Nest purse-like, with porch, ornamented with scraps of bark, paper and caterpillar frass, and attached to twig over stream, or suspended from bush or exposed roots along earth cuttings in hilly country. Clutch 1–3 eggs, white or cream, with brown or reddish-brown speckling, occasionally almost completely covered with brown suffusion of varying intensity. No other information.

Movements. Not recorded.

Status and Conservation. Not assessed. Restricted-range species: present in Western Ghats EBA. Common. Range possibly extends farther S, as reported from Nilgiris and presence suspected elsewhere in Kerala, but confirmation required.

Bibliography. Ali (1932, 1969), Ali & Ripley (1974), Cheke & Mann (2001), Mann (2002), Mukherjee (1981), Oates (1890a, 1890b), Rasmussen & Anderton (2005b).

119. Crimson Sunbird

Aethopyga siparaja

French: Souimanga siparaja **German:** Karmesinnektarvogel **Spanish:** Suimanga Siparaja
Other common names: Eastern Crimson Sunbird, Yellow-backed/Goulpourah/Scarlet-throated/Scarlet-breasted Sunbird

Taxonomy. *Certhia siparaja* Raffles, 1822, Sumatra.

Forms a superspecies with *A. vigorsii*, and often treated as conspecific. Geographical variation sometimes well marked; some distinctive races, e.g. *seheriae* and *magnifica*, perhaps merit separation at species level. Conversely, poorly differentiated *heliogona* may be better synonymized with nominate; also *labecula* with *seheriae*, and these two intergrade in N West Bengal and Bhutan. Nominative race intergrades with *transgensis* on W coast of Malay Peninsula. Many additional races described, all considered insufficiently distinct to warrant recognition: thus, off W Sumatra, *tinoptila* (from Pulo Siemat, near Simeulue I), *heliophilica* (Pulo Bangkaru, in Banyak Is), *niasensis* (Nias I), *melanetra* (Pulo Lasia), *siberu* (Siberut I) and *photina* (North Pagai I) are included in nominate, as also is *ochropyrrha* (Pulo Rittan, in Anamba Is); *mussooriensis* (Mussoorie, N India), *miles* (Nepal), *andersoni* (Sawaddy, E of Bhamo, in N Myanmar) and *viridicauda* (Tengyueh, in Yunnan, in S China) all subsumed in *seheriae*; *terglanei* (Bangladesh) included in *labecula*, and *heliotis* (Dome I, in Mergui Archipelago) synonymized with *cara*; and *marinduquensis* (Barrio Canat, Boac, Marinduque), formerly erroneously treated as a race of *Leptocoma sperata*, is merged with *magnifica*. In addition, there may be a further undescribed race in Bangladesh. Fifteen subspecies recognized.

Subspecies and Distribution.

A. s. seheriae (Tickell, 1833) – Himalayan foothills in India from W Himachal Pradesh (Kangra) E to Sikkim and Bhutan, S to N West Bengal, E Bihar, E Madhya Pradesh and Orissa (possibly N Andhra Pradesh), and W Bangladesh.
A. s. labecula (Horsfield, 1840) – Bhutan, NE India (N West Bengal, Assam, Arunachal Pradesh, Meghalaya, Nagaland, Manipur) and Bangladesh S to Chittagong Hills, E to Myanmar (except S), S China (S Yunnan), NW Laos and NW Vietnam.
A. s. cara Hume, 1874 – S Myanmar and Thailand.
A. s. nicobarica Hume, 1873 – S Nicobar Is (Great and Little Nicobars, Kondal I, Meroe I).
A. s. tonkinensis E. J. O. Hartert, 1917 – NE Vietnam and S China (SE Yunnan E to W Guangdong).
A. s. owstoni Rothschild, 1910 – Naozhou I (SW Guangdong), in S China.
A. s. mangini Delacour & Jabouille, 1924 – SE Thailand and C & S Indochina.
A. s. insularis Delacour & Jabouille, 1928 – Phu Quoc I, off S Cambodia.

A. s. transgensis Meyer de Schauensee, 1946 – S Thailand and N Malay Peninsula.

A. s. siparaja (Raffles, 1822) – Malay Peninsula (S of Narathiwat), Anamba Is (E of Peninsular Malaysia), Sumatra (except Aceh) and satellite islands, and Borneo and associated small islands (except Natunas).

A. s. natunae Chasen, 1935 – Natuna Is.

A. s. heliogona Oberholser, 1923 – Java.

A. s. magnifica Sharpe, 1876 – WC Philippine Is (Marinduque, Tablas, Sibuyan, Panay, Negros, Cebu).

A. s. flavostriata (Wallace, 1865) – N Sulawesi.

A. s. beccarii Salvadori, 1875 – C, S & SE Sulawesi, Kabaena, Muna and Butung.

Descriptive notes. Male 11.7–15 cm, 4.8–9 g; female 10 cm, 5–6.9 g. Male nominate race has forehead to centre of crown glossed purple-green, hindcrown and side of head to back and lesser upperwing-coverts crimson, rump yellow, uppertail-coverts and tail black (uppertail-coverts sometimes glossed green), elongated central rectrices metallic purple; upperwing feathers (except lesser coverts) dark brown, edged olive; chin and throat to breast scarlet, metallic purple-blue moustachial streak, underparts olive-grey; iris dark brown; upper mandible dark brown, black at base, lower mandible horn-brown; legs dark brown.

Differs from *A. vigorsii* mainly in smaller bill, paler general appearance. Female is greyish-olive on crown, nape and mantle, back olive, rump and uppertail-coverts olive-yellow; tail black, edged olive on base of outer webs, outer webs tipped pale grey, central rectrices olive, wings dark brown, edged ochraceous olive; throat light grey, sometimes with some dull red, breast olive-grey, rest of underparts light olive, some yellowish streaking on upper belly, undertail-coverts yellow, and long flank feathers yellowish-white; bare parts as male. Immature male is like adult female, but has scarlet chin, centre of throat and breast, mantle and shoulders, and yellow patch on back and uppertail-coverts; juvenile female greyer and less yellow than adult. Race *natunae* male has paler grey underparts than nominate; *heliogona* is very similar to nominate, but male has some orange mixed with yellow of rump patch, and belly paler grey; *flavostriata* male differs from nominate in having much more pronounced yellow streaking on scarlet throat, metallic blue forehead, moustachial stripes and tail, extensive red margins on upperwing, broad yellow rump patch and dusky belly, female has olive back with slight carmine feather tipping; *magnifica* is larger than previous and has stronger bill, male has metallic purplish gloss on black forehead and tail, crown dark red, rump bright orange-yellow, belly to undertail-coverts black, female dark olive-green head, back and rump, varying amounts of red on scapulars, back and wings, black tail edged red, underparts grey-green; *beccarii* resembles nominate, but female has red back; *seheriae* has longer and more curved bill than nominate, male differs from it in having forehead to centre of crown glossy emerald-green, back brighter crimson, olive lower back with concealed golden-yellow patch, uppertail-coverts and narrow central rectrices glossy green, latter considerably more lengthened than in nominate, rest of rectrices black, outer pair tipped dark grey, much more extensive red below, lower underparts light yellowish-olive to olive-grey, female differs from nominate in having much longer central rectrices; *labecula* of both sexes is darker and richer above and below than previous; *cara* male has green gloss on crown; *nicobarica* male differs from last two in having crown and tail violet-purple, nape dark red, lower mantle blackish, throat to breast orange-red, rest of underparts olive-grey, and central tail feathers not elongated; *tonkinensis* male has more extensive yellow on rump and back than nominate, lacks green on uppertail-coverts, has central rectrices moderately elongated and not markedly narrowed; *owstoni* male has brown nape, dark crimson throat with blackish (not yellowish) feather bases, olive-green abdomen; *mangini* male differs from nominate in having purple gloss on crown; *insularis* male differs from nominate in having belly, lower breast and flanks paler grey; *transgensis* male differs from nominate in having lower breast and belly more olive, becoming yellowish in centre, and wing edged also more olive. **VOICE.** Song, often in flight, a loud sharp or chirping trill; described also as very high-pitched, dry, metallic, hissing, clipped "psip-psip, psip-psip" (first notes much lower and louder) given in rapid short series, quickly repeated for long periods with or without pauses. Calls include a metallic, clicking "zit-tit", a soft "siesiep-siesiep", and a quickly upslurred "shwip!"; short segments of song may sometimes be used as calls.

Habitat. Various forest types, including mangroves, heavily disturbed and regenerating secondary forests, forest edge, also parkland, secondary growth and scrub in open country, coastal vegetation, coconut groves, plantations and gardens, particularly around flowering and fruiting trees; usually avoids closed-canopy forest. Mainly in foothills to 1200 m, occasionally to 2000 m, lower during winter months; recorded to 1500 m in Nepal, 1690 m in Bhutan; sea-level to 1190 m in Borneo, 50–1500 m in Sulawesi, and sea-level to 1000 m in Philippines.

Food and Feeding. Insects, spiders (Araneae) and nectar. Forages in pairs and singly, also in family parties, usually low down but occasionally in canopy. Nectar taken from e.g. *Malvaviscus arboreus*; robs flowers of nectar by piercing corolla bases.

Breeding. Season Feb–Oct in Indian Subcontinent; laying recorded in Jan–Feb and Apr–Jun in Myanmar, calculated as Mar, Jun and early Jul in Malay Peninsula, recorded in Apr in Sumatra and Borneo, in all months except Aug, Oct and Nov in W Java, and Feb–Jun (nestlings in May) in Philippines; nestlings in Sept in Sulawesi. Nest a concealed, attenuated, pear-shaped bag, side entrance usually with porch, woven from fine grass, palm fronds, vegetable down, rootlets, moss and cobwebs, decorated with oddments such as cobwebs or bark, or clothed with rootlets on outside, attached to tendrils or palm fronds 0.15–2 m above ground, sometimes under overhanging bank. Clutch 1–3 eggs, matt or slightly glossed, highly variable, pinkish, with sparse spots and fine lines of dark reddish-brown and clouded light reddish-brown (chiefly at blunt end or densely and uniformly spotted), or pale salmon-pink with dark red blotches and speckles, or white to cream, speckled brown to reddish-brown, or greenish-white and covered with greenish-grey speckles; no information on incubation and nesting periods. Nests parasitized by Asian Emerald Cuckoo (*Chrysococcyx maculatus*) in India; observed to feed juvenile of non-parasitic Yellow-billed Malkoha (*Phaenicocorypha calyculata*) in Sulawesi.

Movements. Seasonal altitudinal movements in Himalayas. Sight record from Pakistan (Islamabad) in winter months.

Status and Conservation. Not globally threatened. Generally common throughout wide range; uncommon to rare on Butung (off SE Sulawesi). Occurs in many protected areas, such as Chitwan National Park, in Nepal, Dibru-Saikhowa National Park, in India, Cuc Phuong National Park, in Vietnam, Way Kambas National Park, in Sumatra, and several reserves in Borneo.

Bibliography. Ali & Ripley (1974), van Balen (1993), Birand & Pawar (2004), Blasius (1897), Cheke & Mann (2001), Coates & Bishop (1997), Dickinson *et al.* (1991), Étiénope & Hùe (1983), Fleming *et al.* (1976), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949), Inskipp & Inskipp (1985), Kennedy *et al.* (2000), King *et al.* (1975), MacKinnon & Phillips (1993), Mann (1996, 2002), van Marle & Voous (1988), McGregor (1909), Medway & Wells (1976), Mees (1986), Mey (2000), Nash & Nash (1985), Oates (1890b), Ogilvie-Grant & Whitehead (1898), duPont (1971a, 1971b), Prinzing & Jackel (1986), Prinzing *et al.* (1989), Rand & Fleming (1957), Rasmussen & Anderton (2005b), Robson (2000b), Rozendaal & Dekker (1989), Smythies (1960, 1986), Smythies & Cranbrook (1981), Vyas (2002), Wells (2007), White & Bruce (1986).

120. Javan Sunbird

Aethopyga mystacalis

French: Souimanga écarlate **German:** Scharlachnektarvogel **Spanish:** Suimanga de Java
Other common names: Violet-tailed (!)/Scarlet Sunbird

Taxonomy. *Nectarinia mystacalis* Temminck, 1822, Java.

Forms a superspecies with *A. temminckii*, previously considered conspecific. Monotypic.

Distribution. Java.

Descriptive notes. Male 12 cm, female 9 cm. Male has bright crimson head to breast and back, except for iridescent purple crown and malar stripe, yellow streaking on breast; rump yellow, uppertail-coverts and long graduated tail dark iridescent purple, lesser and median upperwing-coverts crimson, remiges and remaining coverts blackish; belly grey, flanks whitish; iris dark brown; bill and legs brown. Female has grey head, paler on throat; rest of plumage olive, paler below, with flanks whitish; bare parts as male. Juvenile is similar to female, but greyer. **VOICE.** Soft but ringing "tseep-tseep, cheet-cheet".

Habitat. Hill dipterocarp forest, lower montane forest and secondary forest, and forest edge; usually at 800–1985 m, once at 2300 m, but occasionally down to near sea-level.

Food and Feeding. Little information. Diet thought to comprise nectar and small arthropods. Forages in pairs in upper levels of forest.

Breeding. Breeding in almost all months; laying recorded in Jan, Mar–Jun and Oct. Nest pendulous, said to be similar to those of other sunbirds, otherwise undescribed. Eggs unglossed or slightly glossed, white or greyish-white with few greyish-brown spots. No other information.

Movements. Nothing recorded.

Status and Conservation. Not assessed. Restricted-range species: present in Java and Bali Forests EBA. Not uncommon.

Bibliography. van Balen (1992, 1993), Cheke & Mann (2001), Hoogerwerf (1949, 1950), Hoogerwerf & Rengers Hora Stecama (1938), MacKinnon (1988), MacKinnon & Phillips (1993), Mees (1986).

121. Temminck's Sunbird

Aethopyga temminckii

French: Souimanga de Temminck **Spanish:** Suimanga de Temminck
German: Temmincknektarvogel
Other common names: Scarlet Sunbird

Taxonomy. *Nectarinia temminckii* S. Müller, 1843, Mount Singalang, 1600 feet [c. 490 m], 0°24' S, 100°20' E, Sumatra.

Forms a superspecies with *A. mystacalis*, previously treated as conspecific. Birds from Mt Dulit, in NW Borneo, described as a geographical race, *peretti*, but this considered unsustainable. Monotypic.

Distribution. S peninsular Thailand, Peninsular Malaysia, Sumatra and Borneo.

Descriptive notes. Male 13 cm, 4.6–6.1 g; female 10 cm, 5 g. Male has lateral crownstriae that meet in a patch on central nape, and moustachial stripe, glossed purple and violet; lores blackish, rest of head to back, upperwing-coverts and breast scarlet; rump yellow, lower rump brownish with purple gloss, uppertail-coverts glossed purple and violet; tail blackish-brown with scarlet edging, elongated central feathers mostly scarlet with dark centres; remiges dark brown with golden-olive edging; underparts below breast grey, with centre of belly yellowish, flanks whitish; iris brown; bill and legs black to dull brown. Female has head grey, with narrow white eyering; hindneck and rest of upperparts olive-green; tail sooty olive edged warm golden-olive to coppery red on outer webs; lesser and median upperwing-coverts and tertials as back, greater coverts olive-green with sooty brown inner webs, remiges sooty brown with bright olive fringes, often becoming more bronzy or coppery red on primaries; underparts whitish grey clearly tinged grey olive on chin to breast, and olive-green on sides of breast, rear underparts slightly tinged creamy yellow, especially on vent and undertail-coverts; bare parts as male. Juvenile is similar to female, but greyer below. **VOICE.** Soft "cheet-cheet"; rhythmic "tit-ti tit-it tit-it tit-it...".

Habitat. Lowland and hill dipterocarp forests, lower montane forest and peatswamp-forest; generally submontane, but recorded from near sea-level to 1985 m.

Food and Feeding. Nectar, including from mistletoes (Loranthaceae), and small arthropods. Forages singly and, sometimes, in pairs; occasionally joins mixed-species flocks. Very active, mostly in canopy, but exploits all levels of forest.

Breeding. Laying recorded in Feb and fledglings found in early May and early Aug in Malay Peninsula; lays in Oct in NW Borneo (Sarawak). Nest egg-shaped, 12.5 × 6 cm, entrance hole with small porch one-third down from top, made of dry grass and vegetable down, also lined with down, with a few decorations of paper, bark and other plant material, suspended by pointed apex (forming attachment) from small twig. Clutch 3 eggs, undescribed. No other information.

Movements. None known.

Status and Conservation. Not assessed. Generally uncommon. Listed as "Vulnerable" in Malay Peninsula. Occurs in Kinabalu Park, in Borneo.

Bibliography. Cheke & Mann (2001), Gauthier (1994), Holmes (1996), MacKinnon & Phillips (1993), Medway & Wells (1976), Mees (1986), Robson (2000a, 2000b), Smythies (1957, 1960), Smythies & Cranbrook (1981), Wells (2007).

122. Fire-tailed Sunbird

Aethopyga ignicauda

French: Souimanga queue-de-feu **Spanish:** Suimanga Colafuego
German: Feuerschwanz-Nektarvogel

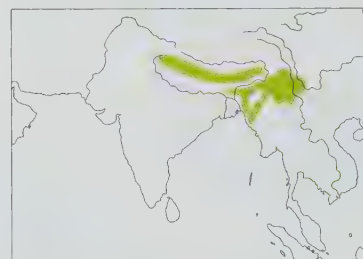

Taxonomy. *Cimyrus ignicauda* Hodgson, 1837, Nepal.

Proposed race *exultans*, described from S China (Salween Divide, in W Yunnan), considered inseparable from nominate. Two subspecies recognized.

Subspecies and Distribution.

A. i. ignicauda (Hodgson, 1837) – N & NE India (from Rajaji National Park and Garhwal E in Himalayas to Arunachal Pradesh, also Meghalaya E to Nagaland and S to Manipur and Chittagongs), Nepal, Bhutan, NE Bangladesh (Sylhet), S China (S Xizang, and W Sichuan S to C Yunnan) and N Myanmar.

A. i. flavescens Stuart Baker, 1921 – NE India (Lushai Hills, in E Mizoram) and adjacent W Myanmar (Chin Hills).

Descriptive notes. Male 15–20 cm, 7.5–9 g; female 8.5–11 cm. Distinctive sunbird with bill only slightly decurved, male with striking plumage tail streamers. Male nominate race has metallic purple-blue crown, blackish side of face, scarlet hindneck and upperparts, yellow patch on lower back; tail, including greatly elongated central rectrices, also scarlet, upperwing olive; throat metallic purple-blue, underparts yellow, washed orange or scarlet on breast, and greyer towards vent; iris dark brown; bill and legs blackish-brown. Male possibly has a non-breeding (eclipse) plumage, but this not confirmed. Female has grey head,

olive upperparts, yellow on rump, olive uppertail-coverts and tail with variable orange wash, upperwing as male; chin to breast olive-grey, yellow lower breast and belly, becoming whitish on vent, flanks olive; may have some orange on breast; bare parts as male. Juvenile is like female, but greyer on head, and tail duller olive, young male brighter yellow below and often with some red on throat and breast; first-winter male as smaller adult female, but tail longer, more yellow below, has yellow patch on back, orange-red on rump, uppertail-coverts and tail, sometimes red or orange on underparts. Race *flavescens* male is shorter-billed than nominate, tends to have slightly smaller iridescent cap, shorter tail and much less scarlet in yellow of breast, female paler and brighter olive above than nominate, with more and brighter yellow on rump, more red on tail, brighter yellow on throat and breast (but no orange). **VOICE.** Song a series of descending very thin, high-pitched, well-separated notes. Calls include high-pitched repeated "dzdzdzdzdzdzdzdz"; high sharp "tsitsitsitsi...tsi...tsi...tsi", last 2 notes slower; rapid staccato twittering.

Habitat. Coniferous and oak forest, particularly with rhododendron (*Rhododendron*) understorey, also juniper (*Juniperus*) scrub above tree-line; 3000–4880 m in summer, and 610–2900 m in winter. In NE Myanmar found in broadleaf lower montane and upper montane evergreen forest, often along edges.

Food and Feeding. Nectar, small insects, and spiders (Araneae). Forages singly and in pairs; outside breeding season also in groups, and joins mixed-species flocks. Catches insects in air.

Breeding. Laying in Apr–Jun in India and nest-building in May in Nepal. Nest built mostly by female, with little, if any, assistance from male; oval, 14 × 7 cm, with small entrance near top, constructed from moss, rootlets, cobweb and papery bark and lined with vegetable down, fine grass and feathers, or fine seed down from fallen pods of simul tree (*Bombax malabarica*), held together with spider webs, scraps of moss and long shreds of grass, or constructed from lichen, and may be decorated with moss and caterpillar frass; suspended from branch of dwarf bamboo or bush within 2 m of ground, or attached by grass and moss to a bracken (*Pteridium*) frond. Clutch 2–3 eggs, pale violet-white covered with purplish speckles, or brick-red with darker brick-red freckles, or white with tiny brown blotches forming broad ring at large end. No other information.

Movements. Seasonal altitudinal movements in Himalayas. Some 3000 birds seen moving N on a Nov morning along Gaoligongshan ridge in W Yunnan, China. Recorded as a vagrant (presumably race *flavescens*) in C Myanmar and once in NW Thailand.

Status and Conservation. Not globally threatened. Widespread and fairly common in India, Nepal and Bhutan; considered very common in Myanmar above tree-line (3900 m) in Adung valley. Probably extirpated from Bangladesh.

Bibliography. Ali & Ripley (1974), Cheke & Mann (2001), Étiénope & Hùe (1983), Fleming *et al.* (1976), Grimmett *et al.* (1998), Inskipp & Inskipp (1985), Inskipp *et al.* (2000), Landmann *et al.* (1991), Meyer de Schauensee (1984), Rand & Fleming (1957), Rasmussen & Anderton (2005b), Robson (2000b), Singh (2000), Smythies (1986), Sultana & Khan (2000).

Genus *ARACHNOTHERA* Temminck, 1826

123. Little Spiderhunter

Arachnothera longirostra

French: Petit Arachnothère **German:** Weißkehl-Spinnenjäger **Spanish:** Arañero Chico

Taxonomy. *Certhia longirostra* Latham, 1790, Tippera District, Bangladesh. Additional proposed races, all considered insufficiently distinct, are *vantyni* (from Jagalbed, Bombay, in W India), subsumed in nominate, and *antelia* (Trang, in S Thailand), *heliocrita* (Selitar, near Singapore), *melanchima* (upper R Siak, in E Sumatra), *hypochra* (North Pagai I), and *exochra* (South Pagai I), all synonymized with *cinireicollis*. For race *cinireicollis*, original spelling often altered to “*cinireicollis*”, but this is an unjustified emendation. Thirteen subspecies recognized.

Subspecies and Distribution.

A. l. longirostra (Latham, 1790) – SW, CE & NE India (Western Ghats from Goa region S to W Tamil Nadu and Kerala; E Orissa and N Eastern Ghats; Darjeeling; Arunachal Pradesh S to Meghalaya and Manipur), E Nepal, Bhutan, Bangladesh, Myanmar E to S China (W Yunnan) and W Thailand (S to Isthmus of Kra)

A. l. sordida La Touche, 1921 – extreme S China (S & SE Yunnan, extreme NW Guangxi), NE Thailand and N Indochina.

A. l. pallida Delacour, 1932 – SE Thailand and C & S Indochina.

A. l. cinireicollis (Vieillot, 1819) – Malay Peninsula (S of Isthmus of Kra) S to and Sumatra and satellite islands (except Banyak Is and Nias I).

A. l. zarhina Oberholser, 1912 – Banyak Is, off W Sumatra.

A. l. niasensis van Oort, 1910 – Nias I, off W Sumatra.

A. l. rothschildi van Oort, 1910 – N Natuna Is.

A. l. atita Oberholser, 1932 – S Natuna Is.

A. l. buettikoferi van Oort, 1910 – Borneo.

A. l. prillwitzii E. J. O. Hartert, 1901 – Java (including Madura I) and Bali.

A. l. dilutior Sharpe, 1876 – Palawan, in W Philippine Is.

A. l. flammifera Tweeddale, 1878 – E & S Philippines (Samar, Biliran, Leyte, Bohol, Dinagat, Mindanao).

A. l. randi Salomonsen, 1953 – Basilan (off W Mindanao).

Descriptive notes. 13.3–16 cm; male 10.3–16.1 g, female 8.8–14 g. Male nominate race has very long, stout, gently decurved bill; plumage olive above, crown feathers dark-centred, side of head grey, lores white, short blackish submoustachial streak; upperwing-coverts olive, remiges dusky-brown with olive edges, tail dark brown, fringed olive and narrowly tipped whitish; throat and breast greyish-white, breast tinged yellow, rest of underparts bright yellow, usually whiter on undertail-coverts, pectoral tufts orange; iris brown to dark brown; bill horn-brown, greyer on gonyes and at base of lower mandible, or black above and pale grey below; legs black, blackish-grey or bluish-grey. Female is similar to male but smaller, has whiter throat, paler base of lower mandible, and lacks pectoral tufts. Juvenile is similar to female but browner, with bright olive fringes on wing feathers, and paler bill and feet. Race *sordida* is similar to nominate, but has dull whitish-grey lores, much shorter bill; *pallida* has much shorter bill than nominate, olive-green of upperparts paler and greyer, very white throat, underparts very pale yellow; *cinireicollis* is very long-billed, has bluish tinge in the grey on side of head, neck and throat, black at corner of mouth, with upperwing and tail greenish-brown, breast to vent yellow, white undertail-coverts; *zarhina* has much longer bill than previous, but shorter wing, and much duller upper surface; *niasensis* also has longer bill and wing, and very pale yellow underparts; *rothschildi* is yellow below (like *cinireicollis*), but bill and often also wing shorter; *atita* differs from last in having longer bill, and yellow of underparts deeper, brighter and more golden; *buettikoferi* is browner and less olive than nominate, has paler pectoral tufts; *prillwitzii* has brighter yellow underparts than nominate, and more orange pectoral tufts; *dilutior* differs from nominate in being more olive-brown on crown, with brown lores, more olive-green above, flanks washed sulphur-yellow, pectoral tufts dull orange, underparts ashy white; *flammifera* differs from preceding race in having faint orange-green wash above, flanks, belly and undertail-coverts yellow, pectoral tufts bright orange; *randi* is similar to last, but bill much longer. **VOICE.** Much geographical variation. Songs include “which-which”, twice per second for c. 2 minutes, continuous “tee-chu”, first note rising, second falling, and squeaky “chew-chew-chew-chew” whistle; in S India described as continuous, syncopated, strident, metallic “clink-clink-clink”, each note an upstroke, and in NE India as simple, metronomic, metallic upstroke “clink-clink...”, recalling Common Tailorbird (*Orthotomus sutorius*), or more varied “wink-link-wink-wink-link-link-wink”, irregular and with more noticeable pitch differences; in Malay Peninsula “tee tay” and “ti tee-tee-tah”, stressed on first syllable. Antiphonal singing occurs, presumably by pair-members. In flight, sharp “weechoo” or “cheek-cheek-cheek”; high-pitched “tik-ti-ti-ti”, first note higher, repeated continuously; harsh metallic “cheet” or “chee-chee”; repeated “chee-chee-chee” or “chip-chee-chee” or “chip-chip”; loud, harsh “sheep” repeated up to 25 times; loud “jit-jit”, increasing in rate and intensity.

Habitat. Understorey of various types of forest, including mangroves, regenerating secondary forest, disturbed and heavily logged forests, forest edge, also coastal vegetation, secondary growth, plantations, gardens and cultivation, particularly around plantains (*Musa*) and gingers (*Zingiberaceae*). Generally below 600 m; up to 1500 m in S India, 75–305 m in Nepal, to 2100 m in China, 1680 m in Peninsular Malaysia, and 2000 or 2200 m in Sumatra, Java and Bali; sea-level to 1400 m in Borneo, and sea-level to 1000 m in Philippines.

Food and Feeding. Nectar, insects, and spiders (Araneae). Forages singly and in pairs, mostly in lower levels of vegetation. Takes insects from spider webs, and from pools of water in vegetation. Nectar-robbing recorded. Pollinates and takes nectar from durian trees (*Durio*); pollinates *Strelitzia nicotai*, also *Musa* species with either erect or pendulous inflorescences.

Breeding. Laying in India in Dec–Aug (chiefly Jan–May) in SW and Jan–Nov (chiefly May–Aug) in Assam; probably Mar–Sept in Nepal, Jan in Thailand, calculated as Dec–May (once early Oct) in Malay Peninsula, May–Jun and probably Aug in Sumatra, in all months except Nov in Java; in Malay Peninsula, egg-laying calculated as Dec–May (once early Oct), nest-building observed mid-Aug, nestlings found in Apr and Oct, and juveniles in all months (most in May–Jun, fewest Sept–Dec); in Borneo, oviduct eggs/active gonads in Jan, Mar–Apr, Jul and Sept–Dec, food-carrying adults (Sabah) in May and Nov and juveniles in Jul–Aug; active gonads in May and Jun in Philippines. Nest a compact cup 10 cm deep, with semi-circular entrance hole on one side (some nests have two entrances), constructed from leaf skeletons, soft grass and vegetable down neatly felted together, lined with fine grass, and attached by rim to underside of banana leaf by cobwebs or vegetable cotton passed through leaf and knotted on upper surface, or made from rootlets, dead leaves, plant fibres and cobwebs in tunnel created by the sewing-up of ginger and plantain leaves; sometimes placed under *Khydia* leaf, or in elephant grass, or under giant creeper or large dock (*Rumex*) leaf or on castor-oil plant (*Ricinus communis*); can be as little as 0.5–2.5 m above ground; nest described also as trough-like, closed at one end to form cup, with entrance tunnel pointing downwards. Clutch 2 or 3 eggs, dull white or creamy with zone of heavy red-brown or purple-brown spotting, or with very few spots, or unglossed pinkish-white to salmon-pink with sparse reddish speckles all over and sharply defined ring of red-brown spots around broad end; no information on incubation and nestling periods. Nests parasitized by Violet Cuckoo (*Chrysococcyx xanthorhynchus*), Asian Emerald Cuckoo (*Chrysococcyx maculatus*), Common Cuckoo (*Cuculus canorus*), Large Hawk-cuckoo (*Cuculus sparveroides*) and Hodgson’s Hawk-cuckoo (*Cuculus fugax*).

Movements. Altitudinal movements recorded on Mt Mulu, in NW Borneo (Sarawak); movements of up to 6 km recorded in Peninsular Malaysia. Thought to undertake local movements in Nilgiri Hills, in SW India. Nomadic in some areas.

Status and Conservation. Not globally threatened. Locally common in India in Western Ghats and NE; very scarce and local in SE Nepal, where recorded also in C; rare in Bhutan; locally common in Bangladesh; common in Tenasserim, but rare elsewhere in Myanmar, generally common in Thailand except E, locally common in S Laos, and common in Peninsular Malaysia; not uncommon in Sumatra; common in Borneo; uncommon in Philippines. Occurs in numerous protected areas, examples of which are Kaeng Krachan National Park and Khao Pra Bang Wildlife Sanctuary, in Thailand, Cat Tien National Park, in Vietnam, Way Kambas National Park, in Sumatra, Gunung Gede-Pangrango National Park, in Java and Bali, Danum Valley Conservation Area, in Borneo, and St Paul Subterranean River National Park, in W Philippines.

124. Thick-billed Spiderhunter

Arachnothera crassirostris

French: Arachnothère à bec épais **Spanish:** Arañero Picogordo
German: Dickschnabel-Spinnenjäger

Taxonomy. *Arachnocestra crassirostris* Reichenbach, 1853, no locality = Sumatra. Proposed geographical race *temminckii*, described from Malay Archipelago, considered inadequately differentiated from birds elsewhere in species’ range. Monotypic.

Distribution. Malay Peninsula (including Singapore), Sumatra and Borneo.

Descriptive notes. 16–17 cm; 15.5–16.4 g. Male is dark olive-brown above, with large yellow patch around eye bordered olive below, and dark olive stripe through eye; flight-feathers with greenish-yellow edging, and tail with greyish-yellow tips and edging on outer feathers; chin to breast greyish-yellow, pectoral tufts yellowish-orange, rest of underparts greenish yellow, becoming yellow on undertail-coverts and flanks; iris brown or dark brown; bill black, horn at base; legs blackish, soles orange. Female is like male but lacks pectoral tufts. Juvenile is thought to be similar to female, but browner and with paler bill. **VOICE.** Hard, nasal “chit chit, chissie-chissie”, also “tch-tch”, also “chek-chek-chek” and variants; captured individual held in hand uttered a wheezing rattle.

Habitat. Various types of forest, once mangroves, also plantations, secondary growth, gardens, and among bananas (*Musa*) and wild gingers (*Zingiberaceae*); sea-level to 1350 m.

Food and Feeding. Insects, including butterflies (Lepidoptera) and termite alates (Isoptera); nectar, including that from mistletoes (*Loranthaceae*), *Eugenia* and *Hibiscus*. Forages mostly singly and in all storeys, often low down.

Breeding. Laying in late Apr, nestlings early Jun and dependent juvenile early May in Malay Peninsula; males with enlarged testes in Jan in N Borneo (Sabah). Nest not certainly described, apparently like a smaller version of that of *A. robusta*. Clutch 2 eggs, ovate, unglossed white, with small black dots and long fine scrawls in zone around broad end. No other information.

Movements. Nothing recorded.
